Operative procedure was by the snare technique following dissection. Sutures were used only when bleeding could not be controlled by direct pressure with sponges. Patients were asked to chew one of the new troches for ten to fifteen minutes at four-hour intervals for five days after surgery.

There were manifest subjective, if not entirely objective, benefits attributable to the medication. The medication acted like a "bacteriostatic bath" over the

oropharyngeal membranes and the muscular exercise and increased salivation initiated by the chewing and swallowing was of value in minimizing and shortening post-tonsillectomy morbidity. There was only one instance of secondary hemorrhage in the patients receiving the troche. The tonsillar fossae appeared unusually clean and showed only minimal inflammation.

Soreness of the throat and pain on swallowing were invariably lessened and patients returned to regular diets rapidly. Reflex otalgia occurred in only two of the patients treated and was so mild that it required no medication. In none of the patients was there a reaction, either systematically or locally. Tolerance and acceptance of the preparation were excellent.—GRANBERRY, C., and BEATROUS, W. P.: *E.E.N. & T. Mo.*, 36:294, 1957.

Chorionepithelioma

Report of a Case with Spontaneous Intra-abdominal Hemorrhage

HARRY B. NEEL, M.D.

Albert Lea, Minnesota

CHORIONEPITHELIOMA is the term applied to the most rapidly fatal malignant tumor encountered in medicine. It is also a tumor of exceptional rarity and of bizarre manifestations.

Three cases described by Chiari in 1877 as carcinoma of the uterine fundus have since been classified as chorionepithelioma and stand as the first reported cases. Additional cases were reported by Sanger in 1893 and by Marchand in 1895. According to Williams, Marchand identified protoplasmic masses with the syncytium, and the individual cells with those of Langhans' layer. Maintaining that the tumor was epithelial in origin, he proposed the term chorionepithelioma.

This tumor occurs in females in the child-bearing period, rarely after the menopause, more rarely in virgins, and in teratomas of the testis. It develops during or after a full term pregnancy, after an abortion, and in cases of hydatidiform mole.

The ages of those affected range from seventeen to fifty-eight years with 67 per cent of cases occurring between the ages of twenty and forty years. In the fifteen cases reviewed by Dilworth and his co-workers the average age was 25.8 years. The incidence is said to increase with the number of pregnancies; Voegelin found an incidence of one case in 13,850 pregnancies; Hepp found one case in 59,300 deliveries. Hydatidiform mole has an incidence of one in 2,500 pregnancies. In St. Luke's Hospital in Duluth in eleven years there were 12,722 deliveries, eight moles and one chorionepithelioma. At St. Joseph's Hospital in Milwaukee there were 24,951 deliveries between 1937-1947; there were fifteen moles and one chorionepithelioma. It is said that this tumor is so rare that a case has not been seen in many large medical institutions.

As stated previously, chorionepithelioma may make its appearance during pregnancy or there may be a latent period of as long as seven years,

as in a case reported by Willeford and Rigdon. Novak believes that chorionepithelioma occurs in only about 1 per cent of moles and that radical treatment of moles is not warranted.

The primary tumor is usually located in the uterus, but cases have been reported in which it has arisen outside the uterus, in the cervix, fallopian tube or a teratoma. Grossly, the tumor may be small and insignificant in appearance. Metastasis may occur to the labia, lungs, diaphragm, liver, spleen, kidneys, brain, mediastinum, thyroid, bone, bladder, urethra and lymph nodes. In fifty-two cases collected by Dorland, metastasis to the lungs were present in 78.38 per cent, to the vagina in 54 per cent, to the kidneys, spleen and ovary in 13.5 per cent, to the liver, broad ligament and pelvis in 10.8 per cent, and to the brain in 5.4 per cent of the cases.

Symptoms usually appear one to four months after labor. The most common symptom is hemorrhage which is said to be present in 90 per cent of cases. It may be "sudden, severe, depleting" and may be secondary to a metastasis, as vaginal, pulmonary or cerebral. Intra-abdominal hemorrhage from perforation of the uterine wall or rupture of a metastasis may be present. Cough or bloody sputum may result from a pulmonary metastasis. In two previously reported cases death was from rupture of the liver at the site of a metastasis.

Nodules may appear in a labium or in the vagina, or the early signs may resemble those of retained placenta, sepsis and subinvolution with abdominal pain, chills and fever. "Bluish nodules in the vagina or vulva which ulcerate should arouse suspicion." In one case enlargement of the liver was the main feature; the original tumor was not found and visceral metastasis were confined to the liver and broad ligament. In another instance bleeding from the bowel resulted from an implant in the jejunum.

As in other conditions, diagnosis must be based upon an evaluation of the clinical manifestations, dilatation and curettage, or biopsy and biologic tests. Persistent bleeding after delivery should arouse suspicion. Curettage frequently fails to provide tumor tissue and therefore does not establish the diagnosis.

Biologic tests for the determination of gonadotropin in the urine are employed in the diagnosis of mole and chorionepithelioma. They are based upon the fact that living trophoblast produces a gonadotropic principle which appears in the maternal blood and urine and, since trophoblast is abundant in both mole and chorionepithelioma, gonadotropin is produced in great quantities. Picard states that in the presence of chorionepithelioma prolan excretion is 10 to 500 times that observed in normal pregnancy. When the Asheim-Zondek or Friedman test is positive some weeks after termination of pregnancy, either full term or abortion, one should suspect mole or chorionepithelioma. The frog test is advocated by Wenger because it is inexpensive, information can be obtained in four hours, and the test is said to be accurate.

One should be aware that the biologic tests are valuable aids but not infallible. After the evacuation of a mole, an Asheim Zondek or Friedman test should be made frequently, according to Jordan. Quantitative titration should be done when a positive test is obtained. An increasing titer causes one to suspect chorionepithelioma.

Treatment of chorionepithelioma is unsatisfactory and the prognosis is poor. If the diagnosis is made while the tumor is confined to the uterus, panhysterectomy is indicated. Roentgen therapy is used and a few authors have reported good results. In advanced cases a fatal outcome can be anticipated regardless of the therapy employed. In sixty cases reported by Park and Lees the mean interval between termination of pregnancy and death was 6.1 months.

Case Report

A married woman, aged twenty-six years, consulted Dr. R. A. Demo on March 20, 1953. She stated that she had not felt good since the birth of her baby a month previously. A severe backache was her main complaint. The pregnancy had been entirely normal and the delivery spontaneous and uneventful. The patient had been confined elsewhere. It was learned that she had had two miscarriages followed by two normal pregnancies.

On examination the patient was found to be well developed, well nourished and in no acute distress. There were a few moist rales at the pulmonary bases. The heart beat was regular. Blood pressure was systolic 110, diastolic 50 mm of mercury. The abdomen was flat and soft; above the umbilicus and slightly to the right there was a mass 5-6 centimeters in diameter which was tender and slightly movable. The entire abdomen was a trifle tender.

On the left wall of the vagina there was a large polypoid mass which was bluish in color and appeared necrotic. On the cervix there was an ulcerated area which, when scraped, bled profusely. It was necessary to clamp the cervix with a ring forceps in order to stop the hemorrhage. The patient was sent to the hospital by ambulance.

In the operating room, under sodium pentothal-oxygen anesthesia, the bleeding area on the cervix was sutured, the polypoid mass was removed from the wall of the vagina and some necrotic appearing material was removed from the uterine cavity. This procedure was carried out by Dr. Demo.

On the following day the hemoglobin was 5.1 gm. One thousand cubic centimeters of blood were administered. On March 22 the patient complained of sudden severe pain in the abdomen and dyspnea. On examination she was found to be in severe shock. She was pale, the pulse was rapid and thready, the blood pressure 44/10. The abdomen was full and everywhere tender. The small mass in the right upper quadrant was again felt. There was dullness in the flanks and a fluid wave was elicited. It was obvious that there was intra-abdominal bleeding. Blood and intravenous fluids were started and the patient taken to the operating room.

Under pentothal-gas-oxygen-ether anesthesia a low mid-line incision was made. The peritoneal cavity was filled with blood, some of which was old and clotted. The uterus was possibly a little soft, but otherwise the pelvic organs were normal. The liver was entirely nodular and there were large nodules on the edge of the liver. These nodules were rather black and reminded one of melanoma. One of the nodules on the posterior inferior surface of the liver was bleeding actively. A biopsy was taken, then gelfoam and sutures were used to arrest the bleeding. The wound was closed.

In spite of the use of numerous transfusions, intravenous fluids and other supportive measures, the patient's condition gradually deteriorated and she expired on March 25, three days following the operation.

Both surgical and autopsy material was examined by Dr. R. W. Koucky who submitted the following, very excellent, description:

"The specimen consists of the uterus and its adnexae, liver and all of the structures of the thorax. The heart weighs 390 grams. There are no tumor implants. The valves show no evidence of endocarditis. The coronaries are soft and large. The left lung weighs 305 grams and the right 310. Both lungs are riddled with innumerable tumor implants, generally about 1.5 cm. and ranging to about 2.5 cm. in diameter. The tumors are reddish

with occasional grey mottling. The lung parenchyma shows no significant change. The hilus of each lung shows tumor masses up to 3 x 4.5 cm. The liver weighs 3,020 grams and contains multitudes of tumor masses. Some of these are up to 6 cm. in size. Many appear within the hepatic veins. The tumors are markedly hemorrhagic and many are very soft, apparently due to necrosis. The surface of the liver is nodular due to these masses and several of these projecting tumors show defects due to rupture or surgery. The uterus is slightly enlarged. In the fundus and to one side there is a circular knob projecting into the cavity. The knob measures 3.5 cm. in diameter and is approximately the same height. It is made up of firm material resembling old blood clots. The material breaks off from the muscle so easily that it is difficult to keep the two together for purposes of section. When the material is removed, the uterine musculature appears intact and not infiltrated. The cervix and vault of the vagina show three areas of ulceration up to 1 x 1.5 cm. One of these shows the sutures of the recent cervical biopsy. The substance of the cervix and vaginal wall is thickened and discolored by hemorrhagic tumor tissue. In its thickest portion this tumor is about 12 mm. The surface of the uterus shows no tumor. The tubes are negative. The ovaries show essentially no change. Many of the follicles are 4 to 5 mm. in size. The multiple corpora lutei often seen with a mole or a chorionepithelioma are not present.

The sections taken from the uterine wall at the base of the hemorrhagic mass show an infiltration of malignant tissue. The cells show extreme variation in size and form and obviously are very rapidly growing. However there are definite evidences of a chorionepithelioma. The cells frequently coalesce to form masses of syncytium. The presence of tumor tissue in the uterine wall and the presence of these syncytial masses positively identifies the tumor as a chorionepithelioma. Study of the deep parts of the uterine wall shows that many of the large veins are filled with tumor tissue. The lesions in the cervix show the same type of tumor and unquestionably the cervical tumor is an implant from the uterus. Sections of lung and liver show the same type of tumor. The tumor in these positions is very much distorted by hemorrhage. Even tiny foci of tumor tissue are surrounded by a relatively large amount of blood and coagulated serum. In some of the masses within the lung the focus of tumor tissue is extremely small. Study of the blood vessels in both the lung and the liver show tumor emboli."

Diagnosis.—Chorionepithelioma.

Summary

1. Chorionepithelioma is a rare, extremely malignant tumor of trophoblastic origin.

2. It usually occurs in females in the child-bearing period, but may occur in virginal and postmenopausal women, and in teratomas.

3. It develops during or after a full term preg-

nancy, after an abortion, and in cases of hydatidiform mole.

4. Hemorrhage is the most common symptom. This may be secondary to a metastasis.

5. A case is reported in which there was widespread metastasis one month after a normal delivery and fatal intra-abdominal hemorrhage from a metastasis in the liver.

Acknowledgment

I am indebted to Dr. R. A. Demo for the privilege of seeing this patient and to Dr. R. W. Koucky for examination of the tissues.

Factors Involved in Screening Patients for Gastric Cancer

CLAUDE R. HITCHCOCK, M.D., Ph.D.
Minneapolis, Minnesota

THE SURVIVAL figures from the best clinics for patients with gastric cancer are still regrettably low. The current nihilistic approach, attempting to show that patients suffering from gastric cancer are predestined to either death or survival at the time their lesion first begins to grow, will gain us nothing toward ultimate improvement of our present situation. If we must wait for the biologically slow-growing cancer to manifest itself, and operate to cure patients only when the disease has been present for a matter of months without taking the life of the cancer victim, we will virtually condemn to death a major portion of those people whom (by virtue of present knowledge) we know could be saved by radical surgical therapy.

Undoubtedly, some authors have the weight of statistical study on their side when they demonstrate that the survivorship from gastric cancer is often better in those patients harboring symptoms for the longest period of time prior to treatment. However, if we are going to provide any possibility for cure to those unfortunate victims (now numbering between 85 and 90 per cent of all gastric cancer patients) who die within a matter of months following the diagnosis of their disease, we must accept the challenge of providing surgical therapy to the patient who has an asymptomatic, but malignant, gastric condition.

Immediately it becomes apparent that *whole-sale examination* of the entire population on an annual basis is impossible; however, *adequate screening* of the population to indicate those people with an increased likelihood for the development of gastric cancer is mandatory.

Physiological Factors of Importance

The association between gastric anacidity, gas-

tric mucosal atrophy, and gastric cancer has long been known. Only during recent decades, however, has a vigorous attempt been made to utilize these readily detectable factors in the screening of possible gastric cancer victims. Recent studies at the University of Minnesota Hospitals indicate that 80 per cent of patients with gastric cancer have complete achlorhydria following triple histamine stimulation of the gastric mucosa. The same studies indicate that cancer patients other than those suffering from stomach cancer have only a 30 per cent incidence of achlorhydria; non cancer patients in a similar age group of fifty years or older likewise have only a 30 per cent incidence of achlorhydria. In the Cancer Detection Research Center at the University of Minnesota, 25 per cent of the 7,786 people examined as of June 30, 1956, were found to be achlorhydric. This association has been utilized as a screening device in the Cancer Detection Research Center for the past eight years. We believe the results of this study indicate the possibility for great improvement in the survivals from gastric cancer on a large-scale basis with wider application of these methods.^{8,9}

All examinees at the Detection Research Center have had a gastric secretory analysis performed on gastric juice obtained by the passage of a Levine tube. The standard sodium hydroxide, Toepfer's reagent, determination has been performed. The gastric mucosa is stimulated with one hypodermic injection of 0.5 mgms. of histamine diphosphate. Twenty-five per cent of our examinees have been either achlorhydric or severely hypochlorhydric (less than 30 degrees free acid) by this method. These people receive routinely each year a gastrointestinal x-ray study, and in those instances where polyps of the stomach are suspected, or known to exist, an air contrast gastrointestinal study is performed.

Since only 25 per cent of persons over fifty years of age are achlorhydric or hypochlorhydric (as found in our own experience), and since over 80 per cent of all gastric cancers occur over

Dr. Hitchcock is Associate Professor of Surgery, University of Minnesota, and Chief of Surgery, Minneapolis General Hospital.

Presented as an inaugural thesis before the Minneapolis Surgical Society, February 7, 1957.

GASTRIC CANCER—HITCHCOCK

TABLE I. GASTRIC CANCERS IN CANCER DETECTION CENTER PATIENTS

March 1, 1948 to June 30, 1956

	Asymptomatic	Symptomatic
Achlorhydric	10 (1 normal—1 year)	11*
Total number	10 (1 carcinoid)	11
Alive and well	5 (50%) (36 months mean)	1 (9%) (18 months)
Positive lymph nodes	3 (30%)	10 (91%)
Local extension	1 (10%)	10 (91%)

*Four were achlorhydric with normal gastro-intestinal series. Re-fused to follow suggestions for re-examinations.

Developed gastric cancers—24, 50, 63 and 64 months later. Three dead.

the age of fifty years, we have limited the group to be tested periodically to those over fifty years of age who have achlorhydria or hypochlorhydria. These two filters enable us to reduce that segment of our population requiring repeated gastric roentgenograms to one-fourth of the group of persons over fifty years of age, or approximately 6.5 per cent of the over-all population.

In Table I we note that the total gastric cancer experience in the 7,786 men and women is twenty-one cancers. Of this group, ten were completely without symptoms at the time the diagnosis was established by x-ray examination, and have been placed in the asymptomatic group. Eleven patients either had symptoms at the time of discovery of their cancer, or were alerted to the necessity of annual x-ray examinations and, failing to follow the recommendations of the Center, developed symptoms of advanced gastric cancer. In this latter category, there were four patients who developed gastric cancers twenty-four, fifty, sixty-three, and sixty-four months after their first normal gastric x-rays performed at the Cancer Detection Center.

In the asymptomatic group there was one patient who might have been delayed in his surgery because of one annual gastric analysis revealing a normochlorhydric stomach, whereas examination the preceding year and the year following indicated a stomach that was definitely achlorhydric. Of the 75 per cent of the Cancer Detection Center patients who were normal as far as gastric secretion is concerned, there has been no indication of a gastric cancer developing during this eight-year-and-three-month-period of follow-up. The completeness of our annual contact with all examinees at the Detection Center makes this fact valid.

In the asymptomatic group of patients there were three (30 per cent) who had positive lymph

TABLE II. CANCER DETECTION CENTER: GASTRIC CANCERS

March 1, 1948 to June 30, 1956

X-Ray Reports	Number	Cancers Actually Found
Probably carcinoma	14	14
Gastric ulcer	28	0
Suspicious area	11	0
Gastric polyps	41 (patients)	4 (10%)
Epigastric mass	3	0
Defect distal esophagus	1	1
Enlarged gastric folds	3	0
Intra-mural lesion	7	1 (carcinoid)
Large luminal mass	2	1 (carcinoma)
		1 (lymphosarcoma)
	110	22 malignancies

nodes at surgery as contrasted with ten (91 per cent) in the symptomatic group. Local extension of the cancer beyond the stomach was found in only one patient out of ten in the asymptomatic group, and is to be contrasted with local extension found in ten out of eleven (91 per cent) in the group with frank symptoms at the time of diagnosis. Five of the asymptomatic patients (50 per cent) are living and well, for a mean survival of thirty-six months. Only one of the patients with symptoms at the time of diagnosis is living at this time, representing a 9 per cent survival.

Analysis of Patients with an Abnormal Finding by Gastric X-Ray

In Table II are listed the conclusions from the roentgenologists as they have examined the patients in the Cancer Detection Research Center with gastrointestinal x-ray. There were 110 people (1.4 per cent of the total; 5.6 per cent of the achlorhydric-hypochlorhydric group) who had a significant lesion noted during x-ray examination. There were twenty-two malignancies found in this group, or 20 per cent of the patients with a positive gastrointestinal x-ray series. It is of interest that the roentgenologists were correct 100 per cent of the time when they diagnosed a lesion as a probable carcinoma; similarly, in those instances where a frank diagnosis of gastric ulcer was made, there were no cancers subsequently proved. Among the forty-one patients who have had a diagnosis of gastric polyps made on x-ray findings and confirmed by gastroscopic examination or surgery, four carcinomas have been found, for a total of 10 per cent. This figure compares closely with the incidence of malignancy in gastric polyps as previously published from the University of Minnesota Hospitals (11 per cent). Of the seven asympto-

TABLE III.
INCIDENCE OF CANCER IN C.D.C. EXAMINEES
March 1, 1948 to June 30, 1956. (7,786 people)

Over-all incidence of cancer (all types)	3.1%—1 in 33
Incidence of gastric cancers	0.28%—1 in 357
Patients with positive gastric X-rays	110
Malignancies found in this group	22—20%

matic patients reported to have an intramural lesion by x-ray, one has been found to have a carcinoid of the stomach. There was one patient with a lymphosarcoma diagnosed as a large gastric luminal mass and this patient is doing well several years following surgery.

From Table III it is apparent that one person out of each 357 persons examined in the Cancer Detection Research Center had a gastric cancer. To date one person out of each thirty-three examined has had a malignancy of one kind or other.

Comparison of Gastric Cancer Incidence

In previous publications we demonstrated an increase of gastric cancer in persons over fifty years of age with achlorhydria and hypochlorhydria of 4.5 times over the expected incidence per unit of population over the age of fifty per year. In the group of patients with pernicious anemia from the gastric cancer precursor study at the University of Minnesota, we have found a 21.3 times greater incidence of gastric cancer than in the similar sample of the population as indicated above. The total increase for both of these groups has been found to be 4.9 times the expected incidence for the general population over fifty years of age. Therefore, it is safe to say that, as a group, the people who are either achlorhydric or hypochlorhydric, or who are suffering from pernicious anemia, have a 490 per cent greater chance of developing gastric cancer than normochlorhydric persons in the population over age fifty.⁸

Pernicious Anemia

The two common denominators that have been demonstrated for patients with pernicious anemia, achlorhydria, and carcinoma of the stomach, have been the absence of free hydrochloric acid and the atrophic gastritis which accompanies this physiologic disturbance. That the patient with pernicious anemia has the predisposition for the development of gastric cancer in the highest degree

yet known cannot be denied. Our recent studies have indicated a 21.3 times greater chance for the development of gastric cancer in the patient with pernicious anemia as against persons with normal gastric function in the population over fifty years of age. We have never been able to prove any difference in the gastric cancer developing in the patient with pernicious anemia as against the patient with achlorhydria. Recent studies have demonstrated, however, that a portion of the people in the achlorhydric group actually are in a preclinical stage of pernicious anemia. This group of people (6 per cent of all achlorhydric) respond to the Schilling test (utilizing radioactive Vitamin B₁₂ cobalt 60) in a manner similar to the patient with frank pernicious anemia. It is entirely possible that the wider application of the Schilling test to the achlorhydric group of people may focus our attention on an even more limited number of people with a significantly greater potential for the development of gastric cancer.^{10,11,14}

Summary

The regrettably high mortality from gastric cancer as we know the problem today indicates the need for further efforts to better control this serious malignancy. Current methods of patient screening and stomach examination could effect an over-all improvement in the gastric cancer picture. There have been 50 per cent of the *asymptomatic* gastric cancer patients surviving for a mean of thirty-six months, as against 9 per cent in the group of patients in the Detection Research Center with frank symptoms at the time of diagnosis.

The serious economic problem involved with mass x-ray screening of large groups of people has been partially met in a satisfactory manner by limiting our efforts in gastric cancer screening to those persons over fifty years of age, and to those who are either achlorhydric or hypochlorhydric. The feasibility of this limitation has been well demonstrated. From our studies it would appear that a rational program of examination would be as follows: Gastrointestinal roentgenograms every six months for the patients with pernicious anemia; gastrointestinal roentgenograms every nine to twelve months for the persons with achlorhydria or hypochlorhydria. The present failure of all forms of specific cancer tests to permit adequate population screening imposes a grave burden of

responsibility upon those who would deny to their fellow men the possibilities of improving their chances for surviving a gastric malignancy by application of the best known methods of our time.

THE MANAGEMENT OF NODULAR GOITER

(Continued from Page 387)

Conclusions

Goiters causing symptoms will be treated. Asymptomatic nodular goiters may not be. Nevertheless, the hazards of carcinoma, hyperthyroidism and pressure on contiguous structures are real in nodular goiter. Therefore, with the risk of prophylactic thyroidal surgery practically zero and with surgical morbidity at a minimum, there is justification in recommending thyroidectomy for the majority of patients who have nodular goiter and who are otherwise in good health.

Some Neglected Practical Points in Allergy

STUART LANE AREY, M.D.
Minneapolis, Minnesota

ANY FIELD of medicine where knowledge is incomplete and results are poor is frequently either completely ignored as being too difficult to master or is casually dismissed as being of no importance. Such is too often the case with allergy. This paper enumerates some practical points which are frequently neglected in dealing with allergic patients.

The diagnosis of allergic disease is made by history, physical examination, and special allergic tests. The history should include a general history, plus a detailed allergic history. A special allergic history form, as suggested by Glaser,¹ will prevent omitting many important facts. Of utmost importance is allowing adequate time to get the patient's complete story. The history is by far the most important tool of the allergist. For example, food allergy is suspected when there is a history of sneezing several times before breakfast, when there is a story of an itching nose or palate, when there is occurrence of fatigue which is not otherwise explained by physical examination, or when there is a history of profuse perspiration in infants associated with feeding. While these conditions can be caused by factors other than allergy, its consideration in the differential diagnosis is often rewarding.

It is almost superfluous to say that an adequate physical examination is necessary for good allergic care. It is most embarrassing to do skin tests for asthma, only to find that the wheezing is due to a foreign body in the lung.

Finally, special allergic tests are used in the diagnosis, of which the most generally useful are skin tests. Skin tests for inhalants correlated with the history are quite reliable, but skin tests for foods are notoriously misleading. Rinkel² repeated skin tests for fourteen common foods ten times in twenty-five patients. He found that 29.1 per cent of negative tests, 26.5 per cent of positive tests and 34.1 per cent of variable tests were associated with clinically demonstrable food allergies. In another

series of 4,264 positive skin reactions obtained from 200 tests on each patient, there were only 567 associated with a positive clinical reaction. Skin reactions not associated with clinical sensitivity are one of the most confusing facets of allergy. How can we best solve this problem? One of the most reliable is by individual feeding tests.

In order to understand the method, it is necessary to understand two points. First is the cyclic theory of food allergy²; that is, in 80 to 90 per cent of cases the symptomatology is related to the frequency of use; as a corollary, if a food is omitted from a diet for a period of months we tend to acquire a tolerance for this food. Second, Rinkel² introduced the concept of masking, i.e., "masking is a temporary decrease or abolition of symptoms following ingestion of a food to which the patient is specifically sensitive." This phenomenon will be seen only when a patient repeats a food in the diet during the time symptoms persist from a previous feeding of the allergic food. This is a clinical facet of allergy and does not occur with every sensitization, but it is a common reason for the patient failing to incriminate a food which is frequently eaten as a cause of symptoms. From a practical standpoint, if a food is omitted from the diet for four days, masking will not be seen. Therefore, in feeding tests, we omit the food to be tested for four days and feed it at noon of the fifth day. A base line of expected symptoms is arrived at by observing the patient at rest for thirty minutes before the food is eaten. Then an average helping of food is eaten and any increase in symptoms is noted for one hour. If there is no increase of symptoms at the end of one hour, a half portion is fed and the patient is observed an additional thirty minutes. As a rule, the number of sneezes, coughs and times the nose must be blown are counted. In addition, the patient's pulse is counted and the occurrence of pruritus, headache or fatigue is noted. This method determines food sensitivities, by positive findings, rather than by the negative findings of the expected relief from removal of the food. In the case of eczema, if we

Presented by title at the meeting of the Northwest Pediatric Society, September 28, 1956.

remove a positive food from the diet, the skin will not clear for about three weeks, but with a feeding test, we note an increase in pruritus within an hour. In order to avoid masking of food, it is necessary that we educate our patient as to unsuspected sources of common food antigens. We customarily supply our patients with lists of food which contain wheat, eggs, milk or corn. Obviously, we do individual food tests only on common foods, not those rarely used, such as caviar and cardamon.

Food allergy may be perennial, that is, unrelated to other environmental factors. It may be concomitant, as for example, the patient who gets symptoms only when he eats a food during the ragweed season. It may be thermal, as for example, the patient who gets symptoms from corn only when there is a sudden drop in temperature. Obviously, individual food tests may fail to disclose a concomitant or thermal allergen, if they are done at a time in which the concomitant allergen or thermal factor is not operating. In addition, certain foods may be cumulative reactors. As for example, the man who can eat eggs every five days, but will get symptoms if they are eaten daily for several days.

In short, if we treat our patient merely on the basis of positive skin tests for foods, our results will be very disappointing. However, if we base our treatment on foods incriminated by actual feeding tests, we will often achieve gratifying results.

With this background, we can discuss therapy. All allergic therapy can be grouped under three categories: avoidance of the offending allergen, hyposensitization when avoidance is impossible, and symptomatic therapy, which includes steroid therapy.

Foods are a common cause of symptoms in infancy. They may cause skin eruptions such as eczema, coughing, or nasal blocking. Diagnosis and treatment are largely worked out simultaneously. Colic is sometimes caused by cow's milk; but it is not the sole or even a frequent cause of this syndrome. A four-day trial of a milk substitute, such as soy bean milk or meat base milk, will suffice for the diagnosis. Another common pediatric problem is recurrent diarrhea. Most physicians are familiar with the fact that the gluten fraction of wheat has been implicated as the cause of the celiac symptoms, but other foods may cause recurrent diarrheas, especially in the

child under three years of age. I can recall one patient with "so-called" celiac disease who had been relieved perfectly on a diet of skim boiled milk, cottage cheese, banana and lean meat. Later on, he had a return of symptoms which were due to an allergy he had developed to banana. His symptoms were completely relieved when banana was omitted from the diet.

Another common syndrome, which may be relieved by avoidance (relative) of the offending allergen, is the common house dust allergy. This is suspected in a child who develops a cold and cough when the house is closed up in the fall and the heat is turned on. These symptoms persist until the heating season is over. Many of these children will show a so called "allergic salute," made by pressing the palm of the hand against the columella of the nose. This gesture serves temporarily to enlarge the nares. Characteristically, this person will report that his nose is better when he is outside the house. On examination the nasal mucosa will be found to be bluish gray, the turbinates boggy, and an excess of eosinophils may be found when the secretion is stained by Hansel's stain. Relief may often be obtained by environmental control of dust. All feathers should be kept out of the room twenty-four hours a day. The dust in the bedroom should be kept at a minimum by having bare or linoleum covered floors, avoiding dry sweeping, dusting the moldings, taking the bed apart and dusting it, washing the curtains at frequent intervals, and keeping the patient out of the room while this dusting is being carried on. Anti-dust preparations may be of some value. In the more severe cases, hyposensitization may be necessary, but it is surprising how many chronic coughs and running noses can be controlled by such a regime.

The so-called asthmatic or spasmodic bronchitis is a condition commonly encountered in pediatric practice in children under ten years of age. Such patients develop high fever and, on physical examination, expiratory sibilant rales are heard which are indistinguishable from a typical asthmatic attack. X-ray examination of the lungs will frequently be interpreted as showing bronchopneumonia. With this syndrome, there is almost always a family history of allergy. These children will respond to antibiotics and anti-asthmatics such as ephinephrine or ephedrine. With advancing years, a certain number will develop true asthma.

While they respond to antibiotics, their requirement can be greatly lessened by proper allergic management. This includes avoidance of house dust, hyposensitization to house dust, if necessary, and avoiding foods to which the patient is sensitive. If the attack is due to infection, the child will become ill and develop fever within twenty-four hours of the onset; if it is allergic in origin, characteristically he will have three to four days of runny nose and cough without fever before the febrile response appears. This is the symptom complex which can be prevented by allergic management.

In the management of the acute attack of asthma the drug of choice is still epinephrine. This can be best given in small doses of 3 minims every twenty minutes until the patient gets relief or until signs of toxicity, such as tremors, appear. Aminophyllin suppositories are quite valuable in the management of the milder episodes of asthma; however, it is easy to use an overdose of this drug. It has been my custom to advise the mothers to cut the infant size suppository in half and use it every four to six hours in treating a child five years of age or under. If relief is not obtained with one or two doses of aminophyllin by rectum, it is well to have recourse to epinephrine. The child who is vomiting and dehydrated with asthma needs extra fluids and should have parenteral fluid therapy in a hospital. Saturated solution of potassium iodide, one drop per year of age, given three to four times a day, is one of the most valuable remedies for chronic asthma or for the allergic cough which is often associated with asthma.

Finally, may I add a personal plea against the indiscriminate use of steroid therapy for allergic disorders. While deaths from asthma do occur, they were certainly rare before the advent of steroid therapy. At the present time, it is rare for a person interested in allergy to have a patient referred (especially one with asthma) who has not been started on steroid therapy. The reason given is always the same, that it was an emergency. The majority of patients can still be controlled by epinephrine, oxygen, hyposensitization and avoidance of offending allergens. The steroids are only symptomatic therapy, and should not be used in place of an adequate allergic program.

Some practical points in the management of eczema follow. First, in using any new ointment on an allergic patient, as suggested by Glaser,¹ it

is well to do a "use test." That is, make sure the ointment itself will not cause a dermatitis, by using it on a small area for twenty-four hours before applying it generously. Next, when applying ointment to an area such as the popliteal or antecubital spaces, a much greater degree of improvement can be obtained by bandaging. As suggested by Hill,⁵ this is best done by using a clean cotton cloth held in place by an elastic bandage. While restraints are sometimes necessary in handling severe eczemas, the majority can be prevented from traumatizing their skin by the use of arm splints and bandaging. There is considerable debate as to whether eczema is allergic, and whether it should be treated by allergic management or the use of topical remedies. If one rules out seborrheic dermatitis, the majority will do best with local therapy plus adequate allergic control.

As to prophylaxis, children with eczema or skin infection should not be vaccinated against smallpox. Their siblings should not be vaccinated against smallpox until such a time as the eczematous infants can be separated from their non-allergic siblings, during the entire course of the vaccination. As you know, a generalized vaccinia may result in serious or even fatal complications. Other immunizations, including Salk vaccine, may be given with very little more risk than to non-allergic child. It is mandatory that allergic individuals be immunized against tetanus, so that there is no necessity of using horse serum for tetanus prophylaxis.

The most challenging and rewarding field for those of us who care for children is the prophylaxis of allergic disorders. We can not change the constitution of an allergic person, but we can prevent the development of food sensitivity. Breast feeding will prevent the development of milk allergy in the newborn period, but unfortunately, it seems to be less and less popular in our present day society. If there is a distinct likelihood of major allergic difficulties in the infant, and breast milk is not available, milk allergy may be prevented by the use of milk substitutes prophylactically as suggested by Glaser.¹ Certain foods have a greater allergic potential in the infant, but seem to be better tolerated in the older child. For this reason, eggs in any form should be omitted until eight to twelve months of age. Orange juice is not necessary as a source of vitamin C, as it can be readily

Mediastinal Emphysema

J. P. MEDELMAN, M.D.
Saint Paul, Minnesota

EARLY in the summer of 1952, one of my internist colleagues and I were attending a meeting of the College of Chest Physicians. Upon my return to my home, I found my older son, who was abnormally healthy on my departure, confined to his bed. His experience drew my attention forcefully to the often unrecognized condition which I am discussing. I would like to recount a brief history of the illness to introduce my topic.

On Friday, June 6, 1952, this eighteen-year-old, exceptionally well-developed male, spent the major portion of the day water skiing. As is usual in that sport, he took several heavy falls. That night he attended a party from which he did not return until early in the morning of June 7, when he retired. He arose about noon the next day and prepared for himself and consumed an average breakfast. He then worked quietly on a boat which he was building. About 2:00 p.m. he came into the house complaining of discomfort in his chest and slight dyspnea which he attributed to his excessive activities of the past day and night. He alternately dozed and rested that afternoon. That evening he declined food, which was unusual. At 8:00 p.m., his mother, a graduate nurse, became suspicious that his symptoms were not due entirely to his fatigue. She found his temperature to be just over 99° F and his pulse to be irregular. A pediatrician, who had seen him through all of his childhood illnesses, was consulted, though the patient's mother realized the incongruity of calling him about this young adult who was then 6' 3" in height and about 180 pounds in weight. The pediatrician, familiar with such "emergencies," advised sedation and a consultation the following morning, Sunday, June 8, between himself, an internist, and a roentgenologist. The patient's symptoms had subsided slightly and the physical findings were less pronounced at the time of the consultation. At the outset, it was agreed upon by the consultants that chest

roentgenograms were indicated. While these were being procured the consultants indulged in a discussion concerning the differential diagnosis. The patient's mother, who was present at the discussion, recalls that several diagnostic possibilities were mentioned with coronary thrombosis figuring among the possibilities. She states that she felt "sick" during the discussion, being greatly alarmed about the patient's pain, fever and abnormal pulse. She, particularly, but apparently all present, were greatly relieved to see the result of the roentgenographic examination (Figs. 1 and 2) which revealed that his condition was the result of mediastinal emphysema. The patient's physical activities were restricted, he was given antibiotics prophylactically for a short time and was allowed to return to his normal regime in about ten days. There has been no recurrence of symptoms or signs since his initial attack, though he is leading a very active life as a jet pilot in the Air Force.

Mediastinal emphysema is a condition which ranks low, chest-wise, in this day and age of "coin lesions," tuberculomas, photofluorograms, hamartomas, bronchogenic carcinoma, segmental resections, and cigarette smoking. However, it is worthy of consideration because it must be included in the differential diagnosis of clinical pictures in which chest pain or discomfort is a signal symptom. In reviewing the literature on this condition, I was impressed by the similarity of the opening paragraph of a preponderance of writers since Hamman in 1938¹ invited his audience, at the second Henry Sewall Lecture in Medicine, to go back with him one hundred years to matters novel and absorbing to physicians of that time. Hamman cited the revolutionary discoveries of Laennec in physical diagnosis. Doctor Hamman's opening paragraphs of this lecture are heartily recommended for all physicians' persual because of his remarks concerning the accumulation and integration of medical knowledge. Incidentally, Dr. Hamman in that lecture described the sign in physical diagnosis which immortalizes

Presented before the Minnesota Academy of Medicine, in January, 1955.

his name. He noted the sign as a "most extraordinary, crunching, bubbling sound" over the apex of the heart at each impulse. His first patient, a physician, could bring on the sound by

its association with alcoholism, due to spontaneous rupture of the esophagus from retching.⁷ I shall report two cases of such a rupture in which one patient was known not to be an alcoholic and

Fig. 1, Case 1. Arrows indicate the mediastinal air.

Fig. 2, Case 1. Arrows indicate the mediastinal air.

shifting his position to that in which both patient and examiner could hear it simultaneously, evidently to their joint delight.

Dr. Hamman, whose name is so strongly linked to mediastinal emphysema, delivered the Frank Billings Lecture on his favorite topic before the American Medical Association in Chicago on June 14, 1944.² His lecture and bibliography brought the topic up to date at that time. Unfortunately, he apparently did not have access to what I believe to be the classic article on the subject. This article was published by the Macklins of the University of Western Ontario in December, 1944.³ The Macklins' exhaustive treatment of the subject covers all necessary experimental, historical and clinical aspects to furnish a well-grounded concept of the condition for anyone especially interested. Evans and Small-don presented a paper entitled "Mediastinal Emphysema" at the American Roentgen Ray Society meeting in October, 1949,⁴ which brought into focus present roentgenologic ideas on the subject. From time to time, articles appear which call attention to the importance of diagnosing mediastinal emphysema. Differential diagnosis from myocardial infarction is often considered an important diagnostic procedure⁵; however, a paper appeared citing two cases in which the conditions were associated.⁶ Another article discussed the condition, suggesting the possibility of

there is good evidence that the other was not. Towbin mentions in the opening paragraphs of his article on the subject practically all of the conditions which are known to give rise to it.⁸

Air may gain access to the mediastinum by way of the interstitial tissues of the lungs. Macklins' experiments and others cited by them demonstrate the mechanism by which rupture of the pulmonary alveolar bases allows the escape of the air principally into the vessel sheaths. Air may also escape from alveolar bases which rest upon interstitial tissue, if the expansion of the bases is greater than that of the underlying interstitial tissue. The sheaths of the pulmonary vessels then carry the air to the mediastinum by reason of the normal physiologic expansion and contraction of the contents of the sheaths and also because these sheaths are the paths of least resistance. The escaped and escaping alveolar air is literally "pumped" along these sheaths. After reaching the mediastinum, air may dissect along the fascial planes into the neck, face and axillae and sometimes down over the chest, arms, abdomen and even the legs. Air may even infiltrate the perirenal tissue by dissecting down the aortic sheath (*Jehn and Nissen: Pathologie und Klinik des Mediastinal Emphysems. Deutch Ztschr. f. Chir., 205:221, 1925, quoted by Evans and Small-don*). Rupture of the mediastinal pleura may follow mediastinal emphysema producing pneu-

mothorax. Pneumothorax is such a common occurrence in the condition that the subjects cannot be considered entirely separately. The Macklins feel that pneumothorax of the so-called spontaneous type usually results from pulmonary interstitial emphysema and mediastinal emphysema. Their arguments are convincing.

It is a medical maxim that air may gain access to the mediastinum by way of the fascial planes of the neck. This view is supported by a study on 120 consecutive post-tracheotomy patients in the St. Louis Children's and City Hospitals in which 25 per cent of the individuals developed mediastinal emphysema.⁹ Surgeons have described hearing air being sucked into the mediastinum during thyroidectomy and tracheotomy. Persons doing this type of work may take some comfort in the Macklins' contention that mediastinal emphysema in these cases is often the result of pulmonary interstitial emphysema due to the condition for which the tracheotomy was performed. Thus they may feel that mediastinal emphysema and pneumothorax discovered after such operations are frequently not a result of their operative procedures.

Air may gain access to the mediastinum by way of the retroperitoneal fascial spaces. I have been unable to find a definite example of such a mechanism in my own experience though I have been shown such instances. In Case 9 in my series it is possible that air entered the mediastinum by way of the retroperitoneal route.

It is obvious that air may gain access to the mediastinum by reason of perforation of the trachea, esophagus, or bronchus.

It is my belief that the most common cause for the production of mediastinal emphysema and its frequent concomitant lesions, pneumothorax and subcutaneous emphysema, is a result of a pressure gradient between the alveoli and the interstitial tissues causing rupture of the alveolar bases. The Macklins state that rupture of the pulmonary alveolar base results from any of three conditions: "(1) those in which there is first an atelectasis of some part of the lung, followed by hyperinflation in adjoining regions of the same or in the opposite lung; (2) those in which there is a general overinflation with or without increased intra-alveolar pressure; (3) those in which there is evident a decreased blood supply to the pulmonary vessels preferably either with increased

intra-alveolar pressure, or with hyperinflation."

In the newborn, the conditions cited by the Macklins to produce a pressure gradient between the alveoli and their supporting structures are apt to be present most effectively. The lungs may not expand properly. This atelectasis allows for hyperinflation of surrounding areas and hyperinflation may be added to by attempts at resuscitation. Then, too, imperfect closure of the ductus arteriosus may be present with poor establishment of pulmonary circulation. Circumstances at the time of birth are such that they would seem to beg for alveolar base rupture, pulmonary interstitial emphysema and ensuing conditions.

Case Reports

Following are brief examples of this condition which I have been able to assemble, with short comments on each. Only typical illustrations are shown.

Case 1 (SJ 19146).—No doubt this patient incurred his mediastinal emphysema as the result of pulmonary interstitial emphysema occasioned by his water skiing on the day his symptoms developed. He undoubtedly fell with inflated lungs and a closed glottis, thus performing involuntarily the Valsalva experiment. It seems evident that the leakage continued for at least twenty-four hours when the symptoms became pronounced.

Case 2 (SJ 49334).—This twenty-five-year-old semi-student played football strenuously three days before admission. He entered the hospital complaining of substernal pain of two days' duration, aggravated by exertion and relieved by assuming the erect posture. It radiated to the left shoulder. He stated that he heard a gurgling sound with every beat of his heart at the onset of the illness. This noise was audible to him when he was lying on his back. Unfortunately, the intern in recording the physical examination failed to mention the sound. He missed the significance of it and it was his impression that the patient had either pericarditis or coronary insufficiency, but the resident in radiology was able to elicit Hamman's sign. The patient was discharged symptom-free after four days. The mechanism of the emphysema was similar to that in Case 1.

Case 3 (SJ 64904).—A ten-year-old boy was admitted to the hospital for evaluation of a suspected congenital heart lesion. His roentgenograms revealed that mediastinal emphysema was present. Hamman's sign was not elicited, probably because of a "Grade IV systolic murmur with thrill heard over the entire precordium and a Grade I diastolic murmur heard at the apex." The mediastinal emphysema was apparently an accidental finding but because of its presence, cardiac catheterization was not carried out as had been intended. The mechanism of the production of mediastinal emphysema was apparently similar to that in the previous two cases, the so-called spontaneous type.

Case 4 (SJ 61440).—An elderly man has a diagnosis of rather rapidly progressive chronic interstitial pneumonia. His symptoms were aggravated late in November, 1954. On admission to the hospital, roentgenograms

demonstrated a 1.5 cm. rent in the esophagus just above the diaphragm. No cause for the perforation was apparent. Mediastinitis and bilateral pleural empyema were present. (Fig. 4) No history of alcoholism could be

Fig. 3, Case 5. Arrows indicate retroperitoneal air.

Fig. 4, Case 5. Arrows indicate mediastinal air. The lungs are markedly congested.

Fig. 5, Case 6. Note axillary subcutaneous emphysema and (central arrow) mediastinal air.

Fig. 6, Case 8. Note similarity to Figure 5.

showed mediastinal emphysema, together with slight collapse of the left lung due to pneumothorax. No pleural blebs were demonstrable. The findings were almost surely based on the mechanism of pulmonary interstitial emphysema following alveolar rupture.

Case 5 (SJ 48112).—A seventy-three-year-old man suddenly became nauseated after his evening meal. He vomited and, upon vomiting, was seized with a severe pain in the epigastrium. Upon hospitalization the findings indicated a ruptured hollow viscus. Roentgen examination revealed slight but definite evidence of mediastinal emphysema and retroperitoneal gas or air. (Fig. 3) Laparotomy was performed and no lesion was found. Two days later a chest roentgenogram made at the bedside demonstrated marked mediastinal emphysema, and the patient died a week after admission. Autopsy

obtained and it was said that the patient had led an exemplary life.

Case 6 (B 39341).—A sixty-four-year-old man suddenly fell ill, thirty-six hours before hospitalization, with vomiting, severe epigastric pain and difficulty in breathing. The striking findings were subcutaneous emphysema on physical examination and mediastinal emphysema on roentgen examination. He was in shock and in such poor condition that surgical intervention was never considered. He lived two and one-half days after admission, developing pneumothorax and subcutaneous emphysema down to the pelvis. (Fig. 5) Autopsy revealed a 3 cm. tear in the esophagus without apparent cause. The attending physician, who was also the patient's nephew, states that the patient did not use alcohol.

Case 7 (SJ 51915).—A forty-two-year-old man had surgical removal of the lower part of the sternum because of a tumor. His roentgen examination after operation furnishes a classic example of mediastinal emphysema

Fig. 7, Case 10. Air in mediastinum due to ruptured esophagus.

Fig. 8, Case 11. Arrow on reader's right points out anterior mediastinal air. Central arrow shows air surrounding hernia sac. Lipiodol given orally partially superimposed on sac.

and his history leaves no doubt as to the mechanism of the introduction of the air. The tumor was a metastasis from carcinoma of the thyroid.

Case 8 (SJ 62833).—A twenty-seven-year-old woman had a segmental resection for a tuberculous granuloma in the left upper lobe. Postoperatively, air was recognized roentgenographically in the subcutaneous soft tissues, in the pleural cavity, and in the mediastinum. The roentgen appearance does not differ from cases in which these conditions arise from other than surgical trauma (Fig. 6).

Case 9 (B 24825).—A middle-aged man underwent a total gastrectomy for gastric and duodenal ulcer. The procedure was poorly tolerated, the patient's condition was not good during the operation, and he died eight hours after the surgery. A roentgenogram of the chest made in the post-anesthesia room revealed mediastinal emphysema and subcutaneous emphysema. This may be an example of air entering the mediastinum by way of the retroperitoneal tissues. It could also be that the mechanism of entry was due to the factors responsible for the patient's poor condition during surgery. Pulmonary interstitial emphysema may have initiated the difficulties.

Case 10 (SJ 32225).—A sixty-two-year-old man was admitted to the hospital for study because of dysphagia. A long constricting lesion of the lower third of the esophagus was discovered on roentgen examination. At subsequent esophagoscopy, the lesion, later shown to be inflammatory, ruptured and mediastinal emphysema ensued. The mechanism responsible for the condition is obvious. (Fig. 7)

Case 11 (M 10874).—An elderly woman, known to have a large esophageal hiatal hernia, entered the hospital for removal of an ingested foreign body in the esophagus. A splinter of bone was removed. Nine hours

later, subcutaneous emphysema was noted. Administration of a little lipiodol by mouth demonstrated a rupture of the esophagus about 4 cm. below the level of the aortic arch. Air was present in the mediastinum anteriorly and also posteriorly where it outlined the hernia sac in an unusual manner. The patient did not survive. In this instance, the means of entry of the air into the mediastinum was also obvious. (Fig. 8)

Case 12 (M 18239).—A fifty-five-year-old man came to the hospital complaining of dysphagia of a few hours' duration after eating a pheasant dinner. Roentgenograms demonstrated a fragment of bone in the lower cervical esophagus, and an attempt to remove it was unsuccessful. Mediastinal air, evidence of mediastinitis and subcutaneous emphysema are seen on a chest roentgenogram made two days later. Another examination, six days after the attempt at endoscopic removal of the foreign body, is interesting in that it makes visible two routes by which air presumably could enter the mediastinum. The presence of a tube in the trachea and an esophageal rupture are seen. This patient did not survive the perforation of the esophagus and the mediastinal infection which followed (Figs. 9 and 10).

Case 13 (SJ 65294).—A new born male infant delivered by Cesarean section three weeks before the expected date of delivery because of Rh factors consistent with possible erythroblastosis, was considered to be doing well for the first hour of life. It was then noted that respiratory difficulty was developing. Roentgen examination revealed marked bilateral atelectasis, mediastinal emphysema and left pneumothorax. Death occurred about twenty-four hours after delivery. After study of the material obtained at autopsy the pathologists

concluded that death was due to the presence of hyaline membrane, although there were microscopic findings of erythroblastosis in the liver and spleen. Conditions were ideal for alveolar rupture with its resultant events.

case is another example of pulmonary interstitial emphysema with its attendant conditions, resulting from over-inflation or raised intra-alveolar pressure, either of which can well happen during the course of a tonsillectomy.

Fig. 9, Case 12. (left) Demonstrates widening of mediastinum due to infection. Arrow indicates air.

Fig. 10, Case 12. (right) Arrow points to esophageal perforation with leakage of ingested lipiodol into mediastinum. Tracheotomy tube (T) was also seen.

Case 14 (SJ 63233).—This newborn full term female infant was in respiratory distress from the time of birth. Examination demonstrated a startling similarity between the appearance of her chest roentgenograms and those of the infant reported in Case 13. She responded well to treatment and seemed to be normal a few days later.

Case 15 (SJ 24298).—Roentgen examination of the chest of a newborn infant in slight respiratory distress revealed several long pockets of air in the mediastinum and evidence of atelectasis in the right lung. Supportive care resulted in an improvement in symptoms. The infant was discharged with his mother on the fifth day of his life. This is a typical case of mediastinal emphysema occurring in the newborn.

Case 16 (SL 87933).—This child was admitted for tonsillectomy. During the operation, subcutaneous emphysema appeared in the neck, which progressed post-operatively to the stage seen on x-ray examination. (Fig. 11) Mediastinal emphysema was also demonstrated. This is seen best on the lateral view where it can be traced in the mediastinum directly along the fascial planes to the cervical region. This case brings out well the importance of the lateral view in demonstrating the condition under discussion. The aberrant air may not always be manifest on postero-anterior projections, especially when consideration is given to the fact that many of the examinations are made at the bedside and film quality is apt to be poor. It is barely conceivable that (1) air entered the tonsillar bed as a result of operation, (2) air could be forced into the parotid duct from the anesthetic implement, or (3) a vesicle ruptured under the pleura with subsequent dissection of this air around the pleura in the hilum and mediastinum. All of these reasons have been advanced for the production of mediastinal emphysema following tonsillectomy. This

Fig. 11, Case 16. (above) Arrows indicate mediastinal and other aberrant air.

Fig. 12, Case 17. (below) Roentgenogram on reader's right shows bone in esophagus. That on left shows emphysema.

Case 17 (SJ 62944).—This case is an example of nearly all the possible known causes of mediastinal emphysema. Four days previous to our observation, this two-and-one-half-year-old boy had been eating chicken pie when he stopped eating, coughed, refused to take much more food and began to regurgitate most of the solid food which he had accepted. That same evening he was seen in another hospital and his parents were told there was nothing wrong. He had been lethargic and ate poorly during the intervening time. On admission a lateral roentgenogram of the cervical region revealed a disproportionately large foreign body (bone) in the upper esophagus. This relatively enormous bone was removed endoscopically, and considerable manipulation was required. An area of puncture was seen on the esophageal wall, so it was known that at least the muscularis had been entered. Because of perilaryngeal edema, a tracheotomy was performed. Since it was feared that an abscess would develop, the soft tissues were then dissected from the left lateral trachea and esophagus and a Penrose drain was inserted. His recovery was rapid and uneventful. He was hospitalized for seven days. This boy had been subjected to severe cough, perforation of at least the muscular coat of the

esophagus, tracheotomy and drainage of the mediastinum. One may take his choice of the possible mechanisms to explain the mediastinal emphysema in this individual (Fig. 12).

Fig. 13, Case 19. ME shows mediastinal emphysema. PT indicates right pneumothorax.

Case 18 (SL 83054).—This female infant coughed and developed respiratory distress while eating peanuts, and roentgen examination failed to make a definite diagnosis possible as to the location of the aspirated material. However, the history and symptoms were such that bronchoscopic examination had to be done. A peanut was discovered on the carina, which explained the failure of the pre-operative recognition of the exact location of the foreign body. The nut was so large that it could not be removed through the glottis and so it was taken out through a tracheal incision. A tracheal tube was required for only a few hours. Before removal of the peanut, there was no mediastinal emphysema, subcutaneous emphysema or pneumothorax. After removal, all three conditions were demonstrated. The mechanism of their production was probably pulmonary emphysema as the "streaky" appearance of the lungs indicated that such emphysema was present. The concept that mediastinal emphysema arises often from opening of the trachea cannot be entirely discredited even though pre-operative roentgenograms did not show it.

Case 19 (SJ 59882).—A sixteen-month-old male infant was admitted with a history of hoarseness for less than twenty-four hours. About four hours prior to admission he was seen at home by a pediatrician because he was developing fever and was coughing. Penicillin was administered and he seemed to be doing well until he was given a bottle of milk about forty-five minutes before admission. He "choked" and developed severe respiratory difficulty at this feeding. On admission, his temperature was 104°F, there was substernal and suprasternal retraction, and breath sounds were absent on the right and over the left upper chest. A diagnosis of acute laryngotracheobronchitis with upper respiratory obstruction was made, and an emergency tracheotomy was done. He improved following this procedure. Twelve hours later a film made at the bedside revealed mediastinal emphysema and pneumothorax on the right (Fig. 13).

One cannot be sure as to the mechanism of the production of these conditions in this case. The observation that breath sounds were absent on the right and over the left upper chest at the time of hospital admission

Fig. 14, Case 21 (above) I indicates inspiratory phase. E indicates expiratory phase.

Fig. 15, Case 22. (below) Typical example of mediastinal emphysema.

would indicate that the conditions were present then. However, here again, it cannot be stated dogmatically that the tracheotomy made before roentgen examination had nothing to do with their production.

Case 20 (SJ 34099).—A seven-year-old boy was admitted to the hospital after being ill for two days with an acute respiratory infection. Poliomyelitis was initially suspected but had been ruled out at another hospital. The admitting diagnosis was tracheitis. Roentgenograms made on admission revealed mediastinal emphysema and subcutaneous emphysema. Therapy, using antibiotics and oxygen, resulted in a rapid recovery and he was discharged on the seventh day of hospitalization. There can be no doubt in this case that air entered the mediastinum and subcutaneous tissues as a result of alveolar rupture, as there were no other pathways available.

Case 21 (SJ 62075).—A twenty-six-month-old girl had a choking spell while eating peanuts five days before admission to the hospital. Fever up to 104°F, frequent coughing and choking spells, refusal to eat well, and vomiting had been present since then. On the day of admission subcutaneous emphysema of the neck and upper chest developed. The initial roentgenograms disclosed mediastinal emphysema, subcutaneous emphysema, left pneumothorax, pulmonary interstitial emphysema and obstructive emphysema of the left lung (Fig. 14). It is interesting to note dissection of air into the sheath of the right side of the diaphragm. All of the findings

					Rib fracture?	

were interpreted as arising from a nonopaque foreign body in the left main bronchus. After removal of the peanut, the patient made a rapid and uneventful recovery and was discharged on the fourth hospital day. The mechanism of displacement of the thoracic air into the several abnormal locations must be pulmonary interstitial emphysema due to alveolar rupture, as no other factor could be identified.

Case 22 (SJ 59103).—A five-year-old girl was admitted with a diagnosis of bronchopneumonia after an illness of twenty-four hours. Mediastinal emphysema was demonstrated on roentgen examination. (Fig. 15) Oxygen therapy and antibiotic medication resulted in a rapid drop in fever, decrease in cough, and in disappearance of dyspnea. The patient was sent home after four days of hospitalization. This is another example of acute respiratory infection with no apparent cause for the accompanying mediastinal emphysema. Thus, it must be concluded that alveolar rupture caused by subsegmental atelectasis and hyperinflation were responsible.

Case 23 (J 5101).—This fifty-year-old man, who fell off a roof while doing construction work, was found to have slight mediastinal emphysema along the right side of the mediastinum on admission. No rib fractures were demonstrated. There was slight atelectasis in the right base. Two days later, there was moderate collapse of the right lung by pneumothorax, marked mediastinal emphysema and marked subcutaneous emphysema of the chest wall bilaterally with extension of the emphysema up into the neck. Free air was also demonstrated in the abdominal cavity. The patient died eight days after admission to the hospital. At autopsy, it was found that there was a fracture of the sternum as well as fractures of the pelvis and of two vertebrae. Here again, it seems that pulmonary interstitial emphysema was the basis for the other findings.

Case 24 (J 9101).—On admission to the hospital, a fifty-eight-year-old man, who had fallen down a stairway, was found to have mediastinal emphysema of moderate degree and marked subcutaneous emphysema over the left side of the chest and extending into the left side of the neck. A fracture, without displacement, of the left fourth rib was demonstrated in the axillary region. There was minimal pneumothorax on the left demonstrated only by a fluid level in the posterior gutter along the diaphragm. Pulmonary interstitial emphysema seems to be the most likely cause for the development of mediastinal emphysema in this patient, although it could be argued that a laceration of the lung caused by rib fracture might be responsible. The patient made an uneventful recovery and was discharged from the hospital in five days.

Summary

To summarize, twenty-four examples of mediastinal emphysema have been presented. The age incidence varies from premature infants to a seventy-three-year-old man. Sixteen of the cases shown were males. In the majority, pulmonary alveolar rupture seems to have been the source of the aberrant air, although it can be argued that in about one-half of the cases some other mechanism was or could have been responsible. Subcutaneous emphysema accompanied mediastinal emphysema in twelve of the cases, pneumothorax was a concomitant finding in eleven, and both were present in seven. Death was the outcome in seven of the cases shown, and in one the condition is an incident in a progressive dis-

Obstetric Conditions Predisposing to Newborn Anoxia and Neonatal Death

EDWARD C. MAEDER, M.D.
Minneapolis, Minnesota

IN RECENT years, as maternal mortality has been greatly reduced, obstetricians have paid increasing attention to the survival rate of newborn infants. Every year in the United States, nearly 40,000 infants fail to survive the first twenty-four hours of life. About 40,000 more never live out the first month. Still, twenty out of every 100 babies born in the United States die before they are ten days old. If we are to further reduce infant deaths, we must succeed in reducing the causes of death in neonatal period (death of infants less than twenty-eight days old). More attention should be given to the immediate postpartum care of the newborn infant, especially during the first eight to ten minutes after birth, when conditions occur which often lead to death in the early hours or days of fetal life. This critical period is definitely the obstetrician's responsibility. Of all the neonatal deaths studied in the 1953 Hennepin County Neonatal Mortality Study, 12 per cent occurred during the first hour of life; almost 60 per cent within the first twenty-four hours.¹

Prematurity is by far the major cause of neonatal deaths. For every term death there are approximately sixteen premature and 150 preventable premature deaths. Schmitz and his associates² found that prematurity with abnormal pulmonary ventilation was the cause of 61.2 per cent of 160 neonatal deaths. Proper care and handling of premature labor and the premature infant represent the ultimate in obstetric and pediatric refinement. Potter³ states that, if we could determine the cause of prematurity and eliminate it, we could cut our death rate in half. If there were not a premature labor, there would not be a premature baby (1000-2500 gms. or 2.2-5.5 pounds). Some premature births are, of course, not spontaneous; they are the result of labor having been induced

or Cesarean section. The exact cause of prematurity can be determined in about 40 per cent of cases. Walker⁴ states that it is not much help to know that a baby died of anoxia or prematurity and atelectasis unless the origin of these conditions is known. Prematurity should be anticipated in order to prevent delay in diagnosis. The safest way still to deliver a premature infant is from below with wide episiotomy and outlet forceps. A minimum of anesthesia or none at all should be used.⁵

"Out of Sight—Not Out of Mind" was the intriguing title used by Dr. Clyde Randall as guest speaker at the 1956 Central Association meeting held in New Orleans (October). He aptly classified anoxias as follows:

1. *Stagnant anoxia*—associated with abruptio placenta, prolapsed cord, and toxemia.
2. *Anemic anoxia*—due to vasa previa, congenital heart disease, and cerebral hemorrhage.
3. *Anoxic anoxia*—(doped baby) caused by drugs (morphine, et cetera) and anesthesia.
4. *Neurogenic anoxia*—seen in congenital cerebrospinal disease.

Anoxia and asphyxia from abnormal pulmonary ventilation are difficult to dissociate and are considered together. Resuscitation of the newborn is chiefly a problem of factors in prevention rather than treatment. By preventing these conditions in the newborn, which are so frequently associated with maternal complications of pregnancy and delivery, the obstetrician can greatly reduce the need of resuscitation. Cyanosis should be heeded as a danger signal and sign of fetal distress. Atlee⁶ feels that a baby should be kept in the obstetrician's hand until he is breathing properly and is of a good pink color. Abnormal pulmonary ventilation and anoxia accounted for 62 per cent of neonatal deaths in both the 1952⁷ and 1953¹ Hennepin County series. This figure is almost identical with that quoted by Schmitz.²

In the 1953 Hennepin County Neonatal Mortality Report of 372 mothers and 379 offspring,¹

Presented as one of three papers in "A Symposium on Anoxia of the Newborn: Its Prevention and Treatment," at the combined meeting of the Minneapolis Obstetric-Gynecology Society and the Minneapolis Pediatric Society, Minneapolis, Minnesota, January 16, 1957.

obstetric complications were encountered in 138 pregnancies, or 37 per cent. As in previous reports, obstetric complications, mostly abnormalities of pregnancy, namely, abruptio placentae, placenta previa, undiagnosed types of antenatal hemorrhage, and toxemia, were considerably more common in premature deliveries. In thirty-five cases of antepartum bleeding, the cause or etiology was listed as unknown. It is felt that a definite diagnosis could have been made in most of these cases. Bleeding in pregnancy usually means some placental separation, which means some hypoxia of fetus. Often an expectant management with sensible precautions does not compromise the mother's safety. In the interest of the fetus and the avoidance of fetal wastage, the best possible procedure is prolonging gestation, if possible, to the relatively safe period of thirty-six weeks and beyond. The chief causes of intrauterine anoxia or asphyxia (the main cause of fetal loss) are placenta previa and accidental hemorrhage, which cause about 40 per cent of perinatal loss. Eastman⁸ claims the opinion is growing that anoxia consequent to various degrees of placental separation is a most important cause of cerebral palsy. It is emphasized that the discard of the bag and use of combined podalic version in placenta previa will greatly reduce fetal mortality.

Early detection and treatment of toxemic factors should be emphasized. Prevention of progression of maternal toxemia, to the point that the fetus is jeopardized by it, is obligatory. Near term there is no problem other than the method of delivery. One should attempt to carry the pregnancy through the thirty-third or the thirty-fourth week to increase, if possible, the premature survival rate. Prior to this time a true toxemia patient poses a serious problem. Many fetuses die *in utero* after two or three weeks of persistent toxemia.

Further reduction in perinatal mortality requires improvement of prenatal care and maternal health starting early in pregnancy, especially in the irresponsible woman and those of low economic social status. Early detection and adequate treatment of anemia with maintenance of proper nutrition should be emphasized. Maternal cardiac disease and diabetes with its often associated oversized immature babies and high incidence of toxemia demand early diagnosis and the aid of an internist. Particular efforts must be made to

find mothers who have a history of premature births, repeated abortions and miscarriages.

In the 1953 Hennepin County Report,¹ the Rh factor was determined in only 70 per cent of the mothers. Erythroblastosis was the cause of neonatal death in 5 per cent of cases. It is well known that babies sensitized to the Rh factor do not tolerate prematurity well. Evans⁹ believes that if prematurity is no longer a major factor in fetal survival, premature delivery is occasionally justified when previous pregnancies have repeatedly ended in early fetal deaths and the father is homozygous Rh. The obstetrician gives diagnostic and preventive care, the pediatrician provides therapy.

The percentage of deaths due to infection in the 1953 Hennepin County Report¹ was about 7 per cent; for full term babies only, 13 per cent. Birth injury mortality was 6.3 per cent in the 1953 series, but, for full term infants only, rises to 10 per cent. The type of delivery is closely associated with birth injury. Trauma of abnormal labor and associated anoxia still takes too great a toll of infant life. In term infants 89 per cent of deaths are due to birth injuries or anoxia, many of which could possibly be prevented. Gold¹⁰ recommends that consultation with qualified obstetricians should be required in all obstetric operations other than low forceps delivery. Some injuries at birth, especially in unskilled hands, are relatively more common in these cases than in the nonoperative deliveries. Fetal salvage with operative delivery has not improved.

All cases of difficult vertex delivery should be given a good trial of second stage labor before a difficult forceps delivery is performed. Schmitz² reported ninety-nine midforceps deliveries with five neonatal deaths. The avoidance of difficult midforceps with better studied management of midpelvic contraction and labor is advised.

Particular care must be exercised in delivery of the premature breech, which carries the highest mortality.⁵ The smaller the infant, the greater the likelihood that it will deliver as a breech. In the 1953 Hennepin County Series, ninety of the 379 neonatal deaths (24 per cent) were delivered by breech.¹ Of this number, seventy-eight were listed as premature. In premature infants the body is smaller than the aftercoming head and the latter may be caught in the incompletely dilated cervix. Calkins¹¹ warns that artificial rupture of membranes should be strictly avoided, if possible, until

the baby is ready to be delivered. Many advocate external version when feasible at thirty-four to thirty-five weeks.¹²

It is estimated that 85 per cent of twin pregnancies terminate prematurely, on the average about three weeks before term, with more than ten times the usual premature death rate. About 15 per cent of all premature infants are twins with incidence of toxemias three times as common as in single pregnancies. Because of the excessive fetal bulk often associated with hydramnios, the cervix may become effaced and two to three cm. dilated any time in the last trimester. Increased mortality in multiple pregnancies is proportionate to the incidence of prematurity and complicated deliveries with the second twin.¹³ Early diagnosis and better prenatal care with restriction of activities from the seventh month is recommended.

Again the relatively high incidence of Cesarean section in neonatal deaths was due to obstetric complications (twenty-two of thirty-two cases).¹ There were thirty-two section deaths, or 8.4 per cent incidence, in the 1953 Hennepin County series. Most of these were done to deliver an immature infant, especially for emergency section in placenta previa or abruptio placentae. Six neonatal deaths were associated with elective section, all of which were immature. It was felt that in several cases there was a definite error in the timing of the repeat elective section. There are frequently miscalculations as to the length of gestation. In these cases of doubt, consultation should be had, plus the necessary x-ray studies. An accurate appraisal of arrival at term is important in order that a premature infant will not be delivered by an ineptly timed and purely elective section. Frequently the records do not show the date of the last menstrual period. I would like to enter a plea for more accurate records as an aid in the study of these charts.

More consideration should be paid to the unborn child and fetal salvage.¹⁴ The use of proper pre-operative medication and anesthesia, affording maximum safe oxygen supply to the infant, is of paramount importance in Cesarean section. The safest anesthesia is usually regional, preferably direct infiltration or local anesthesia. Well-controlled spinal anesthesia administered by trained hands with oxygen inhalation is of value in selected cases. Inhalation anesthesia is still preferred by some when administered safely by a well-

controlled team in competent hands. The cord should be stripped at section before cutting. Many authorities recommend that gastric intubation in the newborn be done routinely in Cesarean section to prevent asphyxia from regurgitated and aspirated amniotic fluid; it seems to have some effect in reducing fetal mortality. A trained resuscitative team, well equipped, should be present at the delivery of all premature infants and at all Cesarean sections.¹²

At a recent Hennepin County Perinatal Committee meeting, the need was brought out for listening to and recording of fetal heart tones during labor and delivery. Several cases have been recently reviewed of normal spontaneous delivery of asphyxiated babies which failed to respond to resuscitation. No record of fetal heart tones prior to delivery could be found. These cases were listed as "cause of death unknown," but fetal distress with death *in utero* due to inadequate placentation was suspected. Intrauterine death and anoxia of fetus arises frequently from cord abnormalities with prolapse and compression. Baden¹⁵ says we might take an average figure of 1 per cent as the incidence of fetal deaths from cord anoxia. Although many of these deaths are nonpreventable, with routine planned care it is felt that one-half of this one per cent might be salvaged. Alertness is necessary for detecting prolapse cord with associated changes in fetal heart tone pattern. Randall believes that the low lying posterior placenta may be a dangerous site, causing pressure on a low cord and be an unsuspected cause of death. It also predisposes to premature rupture of membranes. Placental insufficiency is more apt to be associated with: (1) Post-maturity after forty-one weeks, especially if the amniotic fluid is brown-stained. The placenta is often small and senile, causing a failing oxygen supply to the fetus. (2) Cases of infertility, repeated abortions, and premature delivery. (3) Toxemia—small infarcted placenta (poor placentation). (4) Precipitous delivery. (5) Rapid delivery after pitocin induction. Pierce¹⁶ recently emphasized the indiscriminate use of oxytocics as a cause of preventable perinatal deaths.

Conclusion

Resuscitation of the newborn is chiefly a problem of prevention rather than treatment. There is much that the skillful physician and obstetrician

can do to reduce the incidence of premature birth and perinatal mortality if available knowledge and facilities are fully utilized to prevent and treat obstetric complications. The best possible obstetric care must be followed by adequate pediatric (post-natal) care. Everyone concerned must co-operate in the prevention of newborn infant mortality; this includes, besides the attending medical personnel, the mother herself, the hospital administration and the health officer.

MEDIASTINAL EMPHYSEMA

(Continued from Page 417)

ease. Consideration should be given to the possibility of mediastinal emphysema in a variety of pathologic thoracic conditions.

Addendum

Since preparing this article late in 1954, I have encountered seven additional patients with this condition. Statistically, both by etiology and outcome, they show no significant difference from those included in this report. Examples of mediastinal emphysema produced by surgical opening of the mediastinum are not included as part of this addendum nor in the article proper, except that Cases 7 and 8 illustrate the fact that such cases cause the same roentgenographic findings as those due to other conditions.

Resuscitation of the Newborn

ALBERT J. SCHROEDER, M.D., F.A.A.P.
Minneapolis, Minnesota

NEONATAL asphyxia has been defined as the failure of respiration in the newborn. A more proper term would be apnea neonatorum. Apnea exists when the baby fails to take a spontaneous respiratory movement within thirty seconds of severing the cord.¹

There is ample evidence to show that periods of insufficient oxygenation in the paranatal period produce certain irreversible changes in the cerebral cortex.²⁻⁴ Careful examination of paranatal records of mentally defective infants and children has disclosed a definite relationship between fetal oxygen want and later neurologic defect.⁵⁻⁷

The best clinical classification of asphyxia is that of Flagg:⁸

1. Mild Asphyxia
 - (a.) Infant resists movements of head and limbs
 - (b.) Muscle tone good
 - (c.) Conjunctival reflex present
2. Moderate Asphyxia
 - (a.) Muscle tone absent
 - (b.) No reflex irritation by aspiration of glottis
3. Severe Asphyxia
 - (a.) No response to resuscitation
 - (b.) No respiratory movement
 - (c.) No reflexes
 - (d.) A flicker of cardiac movement

In a review of 2,000 fetal and neonatal deaths Potter⁹ found asphyxia to be the final diagnosis of cause of death in 16 per cent. In the total autopsies, evidence of asphyxia was the pathologic state most frequently found and was present in 19.4 per cent.

Resuscitation is defined as the restoration to life or consciousness of one apparently dead. As commonly used, resuscitation of the newborn represents a method whereby oxygenation of the blood stream is enforced with the intent of establishing a normal spontaneous rhythm of respiration.

Presented as one of three papers in "A Symposium on Anoxia of the Newborn: Its Prevention and Treatment," at the combined meeting of the Minneapolis Obstetric-Gynecology Society and the Minneapolis Pediatric Society, Minneapolis, Minnesota, January 16, 1957.

Technique of Resuscitation

As outlined by Russ,¹ an efficient and thorough resuscitation must include all of the following principles: (1) Immediate warmth; (2) a minimum of handling; (3) a clear open airway; and (4) oxygenation of the blood stream within thirty seconds of severing the cord.

Immediate Warmth.—As implied, warmth should be instituted at the moment of birth. The baby should be received in a warm blanket and covered while the cord is allowed to pulsate. After severing the cord the infant is placed in a "baby warmer" or incubator. Today, many delivery rooms are air-conditioned and in such cases attention to warmth of the infant is particularly important. It is advisable to have the baby removed as soon as possible to the nursery, where, if air-conditioning is present, the temperature and humidity controls are more suitable to the newborn.

A minimum of handling.—An absolute minimum of handling is essential for any baby. The traumatic resuscitations as represented by accordion folding of the baby, tubbing, dilatation of the rectum, massage of the spine, rubbing the hard palate with gauze all cause more serious trauma than any permanent good they could do. Today these methods are largely abandoned. The only amount of handling that good resuscitation requires is the transfer from the delivery table to the incubator.¹

A clear open airway.—It is fundamental that no infant can breathe if a mechanical obstruction is present. Mouth to mouth breathing, stripping the trachea manually, use of the rubber syringe in the mouth are all methods which are based on the presumption that the airway is really clear. In the last analysis, a clear open airway in the asphyxiated infant is obtained by use of tracheal aspiration, either with blind manipulation with the DeLee suction trap or ideally under direct vision via the infant laryngoscope or bronchoscope.

Oxygenation of the blood stream.—This, oxygenation of the blood stream, is the ultimate aim of any resuscitation.

The umbilical cord contains between 80 and 200 cc. of blood, depending on the length and size of the cord and the maturity of the baby. As long as the cord pulsates, the infant is receiving adequate oxygen. To deprive the newborn infant of this blood is to conduct resuscitation under an added handicap.¹

Once the air passages are clear, oxygen may be administered in various ways. In the case of the moderately and severely asphyxiated infant, oxygen via the intratracheal catheter is most efficient. Great care must govern the amount of pressure exerted. Once respirations are established, oxygen is best given in an incubator where it can be humidified and its concentration carefully controlled.

Oxygen is the most potent and physiologic stimulant to the severely anoxic respiratory center.

After Care

Special nurses, trained in the duties expected of them, are truly the difference between life and death in many babies. Close observation for forty-eight to ninety-six hours is a prime necessity. A few points to be observed are as follows:

1. The baby is placed within an incubator. Following resuscitation, placing the head high so as to prevent the weight of abdominal organs on the diaphragm will often prove more beneficial than the conventional Trendelenburg posture. While in this position it is assumed there is continuous nursing observation.

2. Nothing is administered by mouth for twenty-four hours.

3. If apnea occurs, be prepared to repeat aspiration of the airway.

4. Oxygen, well humidified, is delivered to the incubator under temperature and humidity control. Care must be taken to insure proper oxygen concentrations over a period of time.

Drugs as Aids to Resuscitation

After careful investigation and evaluation, the American Academy of Pediatrics in 1954 stated in their text entitled, *Standards and Recommendations for Hospital Care of the Newborn*, "There is little justification for the use of so-called 'respiratory stimulants' such as alpha lobeline, coramine,

metrazol, et cetera. Moreover these drugs may act as poisons if given in excess."¹⁰ At best, these drugs produce a mild and fleeting stimulation with a few incoordinated gasps. The danger of their employment in infant resuscitation is that they can be potent convulsive agents.¹¹

There appears to be no drug of definite *primary* benefit in resuscitation of the newborn, although in certain instances they may offer minor assistance. Circulatory stimulants sometimes improve cerebral circulation and relieve the depression of the apneic infant, as, for example, caffeine with sodium benzoate 25 to 50 mgm., intramuscularly, or adrenaline 1:1000, 0.1 to 0.2 cc. intramuscularly.

Nalline is said to be specific as an antidote in treatment of morphine overdosage. It is not active against respiratory depression due to barbiturates. It may be given intramuscularly or intravenously to the mother prior to delivery or to the infant via the umbilical vein. The dosage is:

Adult, 5 to 10 mgm, intramuscularly or intravenously; *infant*, 0.1 to 0.2 mgm. intramuscularly or intravenously.

Drugs therefore play a very minor part in resuscitation.

Mechanical devices for giving oxygen (simple positive pressure or positive-negative pressure) should have built-in safety devices preventing pressure above certain safe levels. The usefulness of such mechanical devices in resuscitation is still controversial.

Summary

An efficient and thorough resuscitation must include all of the following principles: (1) Immediate warmth, (2) a minimum of handling, (3) a clear open airway, (4) oxygenation of the blood stream within thirty seconds of severing the cord.

For successful operation of these principles is added in liberal quantity, "physician good judgment." Knowledge of how to prevent asphyxia and to combat it when it does appear is a responsibility of paramount importance to the physician concerned with mother and infant alike.

Excision of Small Breast Tumors

G. M. A. FORTIER, M.D.
Little Falls, Minnesota

ASSUMING that nothing is new in the technique concerned with breast surgery, one properly should be chary about presenting an "improved" technique in that field. However, after diligent search of the literature, I have failed to discover that anyone has considered the procedure of excision of a small breast nodule worth writing about. Therefore, without reference to past literature, I shall presume to offer an improved method of excision of a breast tumor.

Without reference to voluminous articles for proof of the point, it is believed that the reader will accept the fact that en masse removal of a small or medium-sized malignant tumor of the breast is associated with no increased danger of dissemination or lessening of the percentage of set interval cures because of a delay of several days, while awaiting the pathologist's report. If, then, these tumors have been and correctly will continue to be removed by the general practitioner, certainly any improvement in the method is a proper determinant for such an article as the one here presented.

One but has to examine a number of such breasts postoperatively to realize that there is definite room for improvement in the technique. In the immediate postoperative period, hemorrhage, resulting in a painful, discolored breast, is frequent. The obvious reason for this result is difficulty in locating and ligating bleeding points. Also, there presents massive hematomas which require removal, always invite infection, and usually result in a gross breakdown of the wound. Later, one sees a depressed scar due, for the most part, to the creation of a gourd-like wound in the fatty tissues which presents only disadvantages in closing.

The following technique results in the development of a "V" shaped wound, facilitates the control of hemorrhage due to accessibility to all parts of the wound at every stage of the procedure, and results in a cosmetically acceptable closure due to ease of coaptation of tissues. When one feels secure in not inviting a scar repulsive to the patient, he more readily removes an increased

amount of breast with the line of incision traversing, in any direction, any segment of the breast.

Technique

It is assumed that, except for very small tumors in which success is uncommon, the operator has determined by previous aspiration that he assuredly is dealing with a solid growth. The first step, and one governing the whole technique, is that of passing a guide silk through the tumor. In very small masses, this may be done with local anesthesia of the skin, allowing the palpating finger of the patient to assist the surgeon. General anesthesia is then administered. This at once fixes the mass (or elusive bit of tissue), assuring the surgeon that upon making the skin incision the neoplasm will not "vanish," leading to a most disconcerting search in a mass of unrevealing fat, resulting, in most such cases, in the wholesale dissection of the breast in the hope that somewhere in the removed portion the pathologist will discover the tumor. A large, curved, cutting needle is employed; the size of the curve varying with the case. This is threaded with a single or double silk, or fine wire of such strength as to withstand firm tension while it is tensed in traction. The needle with its trailing suture passes through the skin at some distance from the lateral edge of the tumor (about 2 cm.), traverses the breast tissue and alien tissue, and emerges the same distance away from the new-growth opposite the point of entry. Now the tissue to be excised has been pinned, and it will not be lost when the skin is incised, unless one carelessly cuts or pulls out the guide sutures.

The next step is quite important to observe. A straight incision definitely *is not made*; rather, the incision begins outside one of the extremities of the guides, swings about in a gentle curve to a comparable point beyond the opposite extremity, then returns in a like manner on the opposite side to the starting point. This elliptical incision is now deepened into the fat. Tension is now placed on the guides, elevating the whole mass out of the wound as the dissection proceeds. Any cancer

cells which have been carried into the tissues by the needles lie safely in the block of tissue to be removed. One continues to exert tension on the guide sutures. This, in a fashion turns the wound inside-out, and such tendency is maintained during the entire procedure. The tissue being attacked may now be boldly, cleanly, and quickly excised.

One notes at once that during the process of dissection, as one draws upon the tension sutures the increasing depths of the wounds continue to approach the surface. The bleeders are always in full view and easily subjected to clamping and ligation. The wedging incision is nicely carried under the tumor. By the time the last firmly holding attachments at the base are reached, all

of the bleeders have been clamped, and, if the surgeon desires, already ligated. This last firm strand is caught with a hemostat, and the tumor separated from the breast tissue. Every recess of the dry, wedge-shaped wound is easily inspected. After ties are placed, the sides of the wound are approximated with "000" plain catgut and the skin with silk. The resulting wound presents a fine scar without indentation.

The above outlined method allows one to conclude the operation with dispatch. It is offered to the reader in the hope that some part of it may be of assistance to him in simplifying an operation which on occasion seems to offer more difficulty than it should.

Continuation Studies

Conjunctivitis

JOHN ALEXANDER McNEILL, M.D.
Saint Paul, Minnesota

EXCEPT for the cornea, the conjunctiva is the most exposed part of the eye. It is subject to infections both bacterial and viral; it shares in that peculiar tissue reaction known as allergy; it is subject to trauma. These are the etiologic factors in conjunctivitis. The types of conjunctivitis can be differentiated clinically and are amenable to different forms of treatment. In addition, conjunctivitis occurs as a part of or during the course of many systemic disorders.

Infective Conjunctivitis

Bacterial Conjunctivitis

Bacteria are the commonest etiologic factors in conjunctivitis. While the conjunctival sac is sterile at birth, a short time later various bacteria can often be cultivated. The common saprophytes are *staphylococcus albus* and diphtheroids.

Factors in preventing pathogenicity are: (1) the low temperature of the conjunctival sac, (2) the flow of tears, and (3) the presence in tears of the bactericidal enzyme lysozyme which rapidly and completely dissolves many airborne saprophytes. Lysozyme, plus certain other undiscovered factors, has the property of inhibiting growth of many ordinary pyogenic cocci, such as, the staphylococcus, hemolytic streptococcus and pneumococcus.

1. *Acute Primary Conjunctivitis*.—Many types of acute bacterial conjunctivitis have been described on a basis of the clinical course of the disease. It is best to lump these cases simply as acute primary conjunctivitis. The clinical picture shows the usual signs and symptoms of inflammation. The conjunctiva is red, especially in the fornices, and it may be edematous, sometimes so much so that it rolls over the cornea. There is usually no pain, but the patient often complains of a scratchiness or a foreign-body sensation. The

discharge present is muco-purulent. In the acute stage the discharge is sufficient to glue the eyelids shut overnight, and when the patient is seen is usually adherent to the lashes and lying in the conjunctival sac.

Organisms Causing Acute Conjunctivitis.—Staphylococci have become by far the commonest causative organism in acute bacterial conjunctivitis.¹ Pathogenic staphylococci may be differentiated in the laboratory from nonpathogenic strains by their ability to ferment mannitol² and by their proliferation of a coagulase.³

CAUSATIVE ORGANISMS

Staphylococcus	or rarely
Hemolytic streptococcus	Gonococcus
Pneumococcus	Koch-Weeks bacillus
	Influenza bacillus
	Meningococcus
	C. Diphtheriae
	And many others

Treatment of Acute Bacterial Conjunctivitis.—In the vast majority of cases acute conjunctivitis is a self-limited disease. The action of the lysozyme, the mechanical washing by the tears, and the natural defenses of the conjunctiva will successfully control the infection in a few days. Cleansing the conjunctival sac by irrigating with saline or Metaphen 1:2500 solution every hour or so should be advised, with special attention to the secretions which tend to accumulate on the eyelashes.

If the infection seems more severe, one of the sulfonamids may be prescribed for local use as an eye drop. Gantrisin 4 per cent or Sodium Sulfacetamide 30 per cent are suitable, as they rarely provoke an allergic reaction.

Solutions of the antibiotics should not be used routinely except in severe conjunctivitis for the following reasons: (1) Many people develop an allergic reaction, particularly to penicillin. (2) Ocular use of the drug may sensitize the patient making its use impossible for more serious in-

Presented at the Center of Continuation Study, University of Minnesota, February 27, 1956.

fections. For this reason, if antibiotics are to be prescribed for local use in the eye, one of those not commonly used systemically should be the drug of choice, e.g., bacitracin or polymixin. (3) There is an increasing incidence of bacterial resistance to the antibiotics. Staphylococci, the commonest offending organism in conjunctivitis, is also the bacteria which most readily develops resistance to antibiotics. Most series report well over 40 per cent of staphylococci resistant to penicillin.⁴

Enthusiastic purists in the field of ocular bacteriology have suggested that cultures should be taken to determine the offending organism in each case of ocular infection before treatment is begun. Since most cases of acute conjunctivitis are self limited, cultures may be reserved for severe and resistant cases.

Some don'ts are as important as the do's in the treatment of acute conjunctivitis.

1. Do not put a patch over the eye. This increases the temperature in the conjunctival sac and dams back the secretions providing the bacteria with better growing conditions.

2. Do not prescribe ointments for daytime use. They are annoying to the patient because they blur his vision and the cleansing action of drops is beneficial.

3. Do not tell the patient to put the drops in his eye "occasionally" or "three times a day." Drugs placed in the conjunctival sac are diluted by the tears very rapidly, especially in the epiphora of conjunctivitis. If drops are prescribed, they should be used every fifteen to thirty minutes the first day, then reduced to every one to two hours the second day if the condition has improved.

The patient should be reminded that conjunctivitis is contagious, so that he will not touch his other eye and will avoid spreading it to others in his family. Children should remain home from school for the short time necessary to cure the disease.

Ophthalmia Neonatorum.—The *staphylococcus* is also the commonest cause of conjunctivitis of the newborn. Treatment is as described above.

Gonococcic conjunctivitis of the newborn, now fortunately rare, begins twenty-four to forty-eight hours after birth. It is characterized by extreme edema of the conjunctiva and lids, a profuse dis-

charge turning purulent after a few days and early corneal involvement if untreated.

In treatment of gonorrheal ophthalmia, good nursing is essential. The discharges should be carefully removed from the eye every thirty minutes. At the beginning of treatment and daily if necessary, two drops of 1 per cent silver nitrate should be instilled in the eye, followed in a minute by saline irrigation. Instillation every fifteen to sixty minutes of drops of one of the newer wide-spectrum antibiotics which affect the gonococcus, such as Aureomycin, should be begun. It is essential to keep the seropurulent discharge irrigated from the eye to prevent corneal damage.

Inclusion conjunctivitis in the newborn (inclusion blennorrhea) is caused by a *virus* which inhibits the female genital tract and may cause a conjunctivitis in the newborn. This conjunctivitis resembles gonococcic conjunctivitis just described but does not appear until five to seven days after birth. The lid swelling and chemosis are less severe than in gonococcic conjunctivitis and the secretion, instead of becoming profuse and purulent, becomes scanty.

In the adult, infection occurs after swimming in pools not properly disinfected. The infection resembles that due to bacteria except that the preauricular lymph node is frequently swollen. Both in adults and newborn the disease subsides under treatment with sulfonamides.

Silver nitrate reaction sometimes gives the appearance of a mild acute conjunctivitis twenty-four to forty-eight hours after birth. Bacteriologic examination provides positive differentiation.

2. *Secondary Bacterial Conjunctivitis.*—In this category are placed repeated subacute infections of the conjunctiva from a source near the eye.

(a) *Conjunctivitis secondary to upper respiratory infection* requires treatment of the general condition for complete cure.

(b) *Conjunctivitis secondary to dacryocystitis.* Chronic dacryocystitis should be suspected as a cause of conjunctivitis in children and in the aged. The diagnosis is made by expressing pus from the tear sac. In recent years, a high proportion of these cases have been complicated by infection with Gram-negative organisms;⁴ therefore, treat-

ment should be controlled by a determination of the offending organisms and their sensitivity to the various drugs. There is almost always obstruction of the nasolacrimal duct so referral may be necessary for restoration of tear drainage before a cure can be accomplished.

(c) *Angular conjunctivitis* is the name given to a type of conjunctivitis due to the *Bacillus Moraxella lacunata*, a Gram-negative bacillus of the hemophilus group. This germ typically inhabits the transitional epithelium at the inner and outer canthi and causes a maceration, excoriation and cracking of the skin at the outer canthus with a localized conjunctivitis in that area.

Treatment is with zinc sulfate 0.5 per cent drops to the conjunctiva and zinc sulfate 0.5 per cent or Chloromycetin 1 per cent ointment rubbed into the area of broken skin.

(d) *Conjunctivitis Secondary to Chronic Blepharitis*. Chronic blepharitis is a very common disease. It is always accompanied by a conjunctivitis and both are subject to acute exacerbations. The squamous type of chronic blepharitis is characterized by redness and thickening of the distal 2 m.m. of the eyelids. Large greasy scales resembling dandruff are firmly fixed to the base of the cilia. Squamous blepharitis is caused by seborrhea.

The ulcerative type of blepharitis shows the above picture plus shallow ulcers at the base of the cilia. It is due to seborrhea plus superimposed infection usually by staphylococci. The accompanying conjunctivitis is apt to be more severe in ulcerative blepharitis.

In both types of blepharitis, the patient should be treated by frequent shampoos followed by application of selenium sulfide suspension 2.5 per cent (Selsun). The crusts should be removed from the eyelid margin by scrubbing with water or Zephiran solution 1:3000. Applications of ophthalmic ointment yellow oxide of mercury 1 per cent—salicylic acid 1 per cent to the eyelid margin at bedtime are helpful.

In ulcerative blepharitis an attempt to eradicate the staphylococci by use of an indicated antibiotic for a limited period is advisable. A solution is used for frequent instillation during the day and an ointment rubbed into the eyelid margin at bedtime.

Virus Conjunctivitis

Many viruses may cause an acute conjunctivitis. Usually the diagnosis is made by absence of bacteria from the culture taken in a resistant conjunctivitis. Many of the virus diseases are accompanied by pre-auricular lymphadenopathy.

1. *Herpes simplex virus* may cause an acute severe keratoconjunctivitis in addition to the more usual ocular forms, namely, dendritic keratitis, disciform keratitis and vesicular lid eruptions.

2. *Epidemic keratoconjunctivitis* is characterized by an acute onset of follicular conjunctivitis and sometimes pseudo-membrane formation. Most cases have enlarged and tender pre-auricular lymph nodes. The cornea shows multiple small round infiltrates, subepithelial, which persist for many months. The acute disease heals itself in three to six weeks.

3. *Molluscum contagiosum conjunctivitis*. A large virus causes a skin lesion consisting of single or multiple papules which are pearly gray in color, with a central depression from which can be squeezed a caseous plug. When these lesions occur on the eyelid, they cause a conjunctivitis. Treatment is excision or cautery of the lesions of the eyelid.

4. *Common wart* (verruca). A common wart on the eyelid margin can cause a subacute conjunctivitis.

5. *Measles* (morbili). An acute catarrhal conjunctivitis typically accompanies measles. Koplik spots may appear on the conjunctiva.

6. *Trachoma* in many parts of the world is a very common eye disease and a serious cause of blindness. In the United States, it is found in certain states and among the American Indians. It is rare in Minnesota.

Characteristically, the disease causes a follicular hypertrophy of the upper tarsal conjunctiva. A pannus (vascularized scar tissue) of the upper half of the cornea occurs later, and scarring of the conjunctiva of the upper cul-de-sac. The diagnosis can be made in the laboratory from epithelial scrapings and material expressed from the follicles in which the typical inclusion bodies will be demonstrated. Treatment is oral and local sulfonamides.

7. *Inclusion conjunctivitis* (inclusion blennorrhea, swimming, bath conjunctivitis).—Inclusion conjunctivitis is seen either as an acute papillary conjunctivitis in the newborn already discussed, or as a subacute follicular conjunctivitis in the adult, with moderate discharge. There is usually pre-auricular adenopathy. The diagnosis can be made by demonstrating the inclusions in conjunctival smears and scrapings. Treatment is sulfonamides locally. The adult type will subside in two to three weeks without treatment or scarring.

8. *Lymphogranuloma venereum* can cause a conjunctivitis with pre-auricular lymphadenopathy.

9. *Acute follicular conjunctivitis of Beal* is an acute follicular conjunctivitis with pre-auricular lymphadenopathy and spontaneous healing. No corneal complications occur.

10. *Cat Scratch disease*. An interesting disease consisting of conjunctivitis, pre-auricular adenopathy, malaise and fever following a scratch on the face by a cat has been described by many authors the past few years.⁵ It is thought to be due to a virus or to leptothrix infection.

Allergic Conjunctivitis

The allergic conjunctivides are characterized in general by: (1) The outstanding symptom is itchiness in contrast to the "pricking" or "pain" or "foreign body sensation" of infective conjunctivitis. (2) The congestion of the blood vessels is less marked, but there is a greater tendency to edema of the conjunctiva, especially near the limbus. (3) Characteristically the discharge is scant and tends to be ropy and tenuous.

Simple allergic conjunctivitis is well known as the ocular portion of the hay fever syndrome. It can, of course, occur without the general manifestations of hay fever.

In addition to the well known allergens, such as foods, pollens, dust, things to be kept in mind in investigating a case of allergic conjunctivitis are cosmetics and medications being instilled into the eye. In this latter connection, pilocarpine, eserine and the antibiotics deserve special mention. The incidence of allergy to the antibiotics among the general population is striking. It has been estimated that up to 10 per cent of the

general population is allergic to penicillin, or at least shows allergic manifestations when it is used topically. Pilocarpine and especially eserine deserve mention because many patients with glaucoma, after using these drugs for years, develop a chronic conjunctivitis characterized by follicles on the conjunctiva of the fornices. Pilocarpine will also cause a more acute allergic reaction, as will pontocaine, butyn and most medications.

Allergic conjunctivitis is frequently accompanied by an *allergic dermatitis of the skin of the eyelids*, particularly in allergies to medications being used in the eye and to cosmetics. Additional etiologic factors in allergic dermatconjunctivitis are eyeglass plastics and metals, fingernail polish, detergents and soaps and other things that may be rubbed by the fingers onto the eyelids.

Treatment of allergic conjunctivitis should first of all be directed toward finding and eliminating the allergen if possible. Relief of the local symptoms may be obtained by use of steroid suspensions locally and by use of the antihistamines locally or by mouth.

Vernal catarrh is the name given to a special type of allergic conjunctivitis, occurring in the warm weather. It is characterized by the above described signs of allergic conjunctivitis—itching, edema, thick mucous discharge—plus two special types of reactions.

In the limbal type of vernal catarrh, there is a gross edema and hypertrophy of the conjunctiva near the limbus so that a regular doughnut of conjunctiva rises and overhangs the cornea. This hypertrophied conjunctiva is grayish-pink in color.

In the palpebral type there occur large soft grayish-pink granulations on the tarsal and fornix conjunctiva, especially that of the upper tarsus, which are flattened and packed together in angular shapes to present a cobblestone appearance. These cause the patient great distress and in severe cases, they may persist and be present all year 'round.

The etiology of this condition is still uncertain. It usually affects boys and young men ages six to twenty. The precipitating factor may be pollen or it may be the warmth of the spring. Emotional factors may also play a part.

Treatment has been much more effective in relieving the symptoms of these very distressed patients since the advent of steroids; suspension hydrocortisone 0.5 per cent locally is used. It

is usually necessary to begin treatment each year at the onset of symptoms and persist until fall. In addition, these patients obtain relief of symptoms if the stringy mucous is removed from the upper tarsus manually or by irrigations. Like so many allergic disturbances, this disease tends to recur for many years, then burn itself out.

If the follicles in the upper tarsus are very large, it may be necessary to remove them, or reduce their size. The preferred method is two or three applications of the *B*-rays of radium. Enough should be used to relieve the symptoms. It is not always necessary to remove the granulations entirely.

Vernal catarrh is common in Minnesota.

Phlyctenular keratoconjunctivitis is not common. This disease is an allergy to tuberculo-proteins and occurs in undernourished children who have a primary tuberculosis complex in their hilar nodes. It is characterized by raised nodules in the bulbar conjunctiva, surrounded by a zone of hyperemia. The nodules break down and form ulcers. They also occur on the cornea where they are accompanied by a leash of vessels from the limbus.

While tuberculo-proteins are thought to be the usual precipitating allergen, other bacterial and viral proteins, notably the proteins of *Staphylococcus aureus* when marginal blepharitis is present, can cause phlyctenular conjunctivitis.

The treatment of choice is hydrocortisone locally and improvement of the child's environment.

Traumatic Conjunctivitis

Trauma must not be forgotten as a possible etiologic factor in conjunctivitis. In acute conjunctivitis, the possibility of foreign body or chemical burn should be investigated. A foreign body in the eye for a few minutes then rubbed or flushed out will leave the conjunctiva congested for several hours, with lachrimation and perhaps a mucous discharge.

Chronic Conjunctivitis

(Generalized Hyperemia Without Secretion)

There are many people whose eyes are constantly a little congested, who occasionally or always have more secretion of mucus than usual, whose eyes water unusually easily, and who come to the doctor detailing such symptoms. They usually are given to using their eyes for prolonged

periods of close work, such as reading. A number of factors singly or in combination must be considered in the etiology or in combination must be considered in the etiology of chronic conjunctivitis.

Bacterial infection, particularly staphylococcal infection, tends to become chronic with the organisms residing in the glands of the eyelid and chronically affecting the conjunctiva, probably through allergy to the bacterial proteins and toxins.

Allergy.—In addition to bacterial allergies, chronic exposure to such allergens, as cosmetics or house dust may bring a very mild chronic response in some individuals.

Trauma and irritations frequently either cause or aggravate chronic conjunctivitis. Dust in industrial situations and tobacco smoke are two common factors of this sort.

Refractive errors may also be a factor contributing to the hyperemia. Also a related factor is the prolonged use of the eyes in substandard illumination.

Patients with chronic conjunctivitis have to be examined and questioned carefully to evaluate which one or combination of these etiologic factors is the cause. Treatment should be directed against the causative factor, but it should take the simplest form, because these patients probably will always have slightly red eyes and may go on using any given prescription for years.

Antibiotics should never be used for chronic conjunctivitis. If any element of infection is present Metaphen 1:2500, Merthiolate 1:5000, or Aqueous Zephiran 1:5000, in drop form, for use four times a day may be prescribed.

Instruction in general eye hygiene is helpful; for example, these patients should be told not to rub their eyes. They should be cautioned to read in good light and to rest occasionally. A useful prescription to be used in an eye cup three times a day or as needed is:

Sodium Bicarbonate	
Sodium Biborate.....	1/0
Rose Water.....	30/0
Distilled Water.....	180/0

Eye drops for prolonged use in chronic conjunctivitis should not contain pontocaine, holo-

caine or other local anesthetics. There is the danger of sensitization, but a greater danger is that of a foreign body lodging in the eye for a long period while the eye is anaesthetized.

Conjunctivitis in Systemic Disease

1. *Acute Exanthemata*. As is well known, conjunctivitis, usually acute in nature, constantly accompanies measles. It can also occur in association with the skin lesions in German measles, in influenza and in most of the acute exanthematous diseases of childhood. The lesions of chicken pox, small pox and even vaccinia commonly occur on the lids and may involve the conjunctiva.

2. *Diphtheria*, already described under membranous conjunctivitis, may occur primarily or secondarily in the conjunctiva.

3. *Parinauds Syndrome*. Several diseases can cause an ulcerative granulomatous conjunctivitis with pre-auricular adenopathy. The disease and the tests necessary to differentiate them are:

Disease	Diagnostic Procedure
Lues	Serology; dark field
Tuberculosis	Smear—Culture
	Guinea pig inoculation
Lymphopathia Venereum	Frei test
Tularemia	Agglutination test
Leptothricosis	Histologic examination of nodules.

4. *Trichinosis*. The first sign may be a redness and edema of the conjunctiva. This disorder is resistant to treatment and the diagnosis may be suggested by excessive soreness on moving the eyes, the extraocular muscles being involved like the other muscles of the body.

5. *Thyrotrophic* disorders might be kept in mind in any usual disorder of the conjunctiva. Early exophthalmos may be unnoticed and the exposure causes conjunctival edema and redness.

6. *Keratoconjunctivitis Sicca* (Sjogren's syndrome) consists of deficient secretion of the lacrimal, salivary and sweat glands, and arthritis, and it occurs in women past the menopause. These patients complain of burning and irritation of their eyes. Also the cornea lacks lustre, and tags of epithelium like short filaments may have

rolled off it. The lack of tears may be detected by *Schirmer's test*. A strip of filter paper 5 m.m. by 35 m.m. is bent so that 5 m.m. hangs inside the eyelid. In five minutes 15 m.m. of the rest of the filter paper should be wet.

Treatment is by artificial tears, 0.5 per cent or 1 per cent methyl cellulose, as needed.

7. *Acne Rosacea* causes a conjunctivitis, but the main eye lesion is a corneal infiltration and vascularization.

8. *Pemphigus* is a rare, acute or chronic, and usually fatal disease characterized by a generalized eruption of bullae. In acute pemphigus, there is a sudden onset, a rapid course to death. On the conjunctiva, as elsewhere on the skin and mucous membranes (throat, mouth), hemorrhagic or purulent bullae arise on previously normal tissue.

Chronic pemphigus vulgaris is more common.

Chronic ocular pemphigus occurs with or without lesions in the mouth and throat and without skin changes.

The cause is unknown, possibly it is a virus.

8. *Erythema multiforme bullosum* is an acute inflammatory disease, characterized by sudden onset of eruptions of many forms, including large bullae surrounded by red halos. There are also bluish red macules, papules and bullae. The duration is short and the prognosis good. Conjunctivitis accompanies it and may be catarrhal, purulent or a severe destructive membranous conjunctivitis causing extensive scarring and even loss of the eye. The ocular form of the disease is called Stevens-Johnson disease. The cause may be a virus or the disease may be a toxic reaction to a drug, such as sulfonamides.

Gout: A Metabolic Disorder

PAUL J. BILKA, M.D.
Minneapolis, Minnesota

THE major problem of gout in clinical medicine today is its recognition. Present therapy is sufficiently effective to relieve almost every sufferer from gout.

Isotope studies have enlarged our knowledge of uric acid metabolism in man but the basic abnormalities are still unclear. Patients with gout have greatly increased miscible pools of uric acid in their bodies in addition to their increased serum levels of uric acid. The cause of this increase is probably due to overproduction of uric acid, rather than the alternatives of decreased breakdown or diminished urinary excretion of uric acid. The normal source of most of the body's uric acid is from protein, and especially nuclear metabolism, plus ingested purines. However, it has recently been shown that the body can form uric acid from such elementary substances as glycine without the intermediate formation of nucleic acid.

Diagnostically, the history of acute recurring attacks of joint pain, with a predilection for the feet, is the most valuable feature that differentiates gout from other forms of arthritis. Typically the attacks are sudden in onset, monarticular, disabling for several days to a week or two and then followed by complete remissions. In its late stages gout may be indistinguishable clinically from rheumatoid arthritis, but the early distinguishing history can and should be elicited.

Tophi, which represent gross deposits of sodium urate crystals, are not early findings but are present in almost 20 per cent of patients in collected series of gout. Serum uric acid levels above 6 mgs. per cent are usual. Occasionally normal levels are found, especially if the patient has taken salicylates in some form for pain relief. Hyperuricemia alone does not justify a diagnosis of gout: leukemia, polycythemia vera, renal insufficiency and certain skin disorders may be responsible. Bone x-ray changes, consisting of punched-out areas and representing osseous tophi, are a relatively late finding. Of great diagnostic significance is the dramatic response of the acute

gouty attack to colchicine. No other type of arthritis will respond in this manner, but therapy must be prompt and adequate.

Colchicine still is the most usual treatment for acute gouty arthritis. The following is the schedule employed:

1. Colchicine (grains 1/100), two tablets for the first dose followed by one tablet every two hours until pain is relieved or gastrointestinal upset occurs.
2. Purine free diet.
3. Liberal fluid intake.
4. Strict bed rest during the attack.
5. Hot or cold applications to the affected joints.
6. Uric acid diuretic and alkali.

Intravenous colchicine is now available and is especially valuable where severe gastrointestinal intolerance prohibits oral medication. Its action is also more rapid. Two to three milligrams is the usual dose, and one to three milligrams may be given as a second dose if relief is not adequate after several hours.

Butazolidin is a very effective drug in acute gout, and has the advantage over colchicine of not causing intestinal upset. An initial dose of 400 mg. can be followed by 200 mg. every two to four hours with expected dramatic relief in six to twelve hours, when the dosage can be greatly reduced.

Treatment during the interval between acute attacks represents a much neglected phase in the complete care of the patient with gout. The aim is to prevent attacks of gouty arthritis and to prevent the deposition of urates in the joints, the kidneys and other tissues. Many patients with severe chronic gout can be restored to normal function if the following program is carefully carried out:

1. Low purine diet.
2. Avoidance of individual provocatives.
3. Urate diuretic with alkali.
 - (a) Aspirin—4 to 6 gms. a day—usually on only three to five consecutive days of each week.
 - (b) Benemid—1 to 2 gms. per day.

Case Presentation

Hypofibrinogenemia

GEORGE R. McNEAR, JR., M.D.
Mankato, Minnesota

THIS case is presented as an example of typical hypofibrinogenemia.

Case Report

Mrs. R. H., thirty-five years old, was a Para IV, Gravida VI, with two living children. Her last normal menstrual period was April 1, 1954, making the expected date of confinement January 7, 1955. Her first visit to the Mankato Clinic occurred on June 2, 1954, at which time she was eight and one-half weeks' pregnant. Physical examination confirmed the findings of pregnancy in a parous female, and the usual laboratory work was performed, and found to be essentially negative. The patient was a known Rh-negative isoimmunized individual, having had one previous stillborn, macerated infant, due to erythroblastosis foetalis.

A summary of her obstetric history disclosed that she had delivered a normal male infant in January, 1947. The patient at that time was known to be Rh-negative and the husband to be Rh-positive. No immunity was found.

Her second pregnancy was in May, 1949, at which time she delivered a normal living male infant, following a prolonged labor due to a brow presentation. There was a retained placenta which was removed manually. During this pregnancy the patient's Rh titer was obtained, and she was not immunized.

In August, 1951, the patient was delivered of a viable male infant, who required considerable resuscitation probably because of a tight cord around the neck. There was no evidence of Rh-isoimmunization.

Her next pregnancy occurred in August, 1952, at which time she was delivered in the seventh month of a macerated female foetus. There was evidence of Rh-isoimmunization with a titer of 1:526 (albumin anti-D).

In 1953, the patient had a spontaneous miscarriage during the third month of pregnancy. There was evidence of Rh-isoimmunization at that time with a titer of 1:500.

At the time of the first obstetric visit, in June, 1954, an albumin antibody titer of 1:512 (anti-D) was found. On August 10 the patient first noted foetal movement. Weight gain, blood pressure, and urinalyses up to this time were within normal limits. Foetal heart tones were heard by the examiner on October 19. By October 25, no further heart tones were heard and the patient had noted no movement for about three days.

A roentgenogram of the abdomen was taken November 1, 1954, at which time there was some evidence of

collapse of the foetal skull bones, suggestive of foetal death. On November 8, a repeat Rh antibody titration was taken, showing a blocking albumin titer of 1:1024 with a negative saline titer. Confirmation of this titration was obtained by Dr. Philip Levine of Raritan, New Jersey.

Toward the end of November the patient noted skin itching, and on physical examination there seemed to be some diminishing size of the uterus, as measured from the symphysis pubis to the fundus.

On December 18, during the absence of this patient's family physician, she was admitted to the hospital because of bright red vaginal bleeding. By dates, she was by this time in her thirty-eighth week of pregnancy; the size of the pregnancy, however, was of a twenty-eight to a thirty-week gestation. A clotting time, done in the office, one week prior to admission, failed to show evidence of coagulation and retraction of the clot after one hour. Because of this, afibrinogenemia was suspected in this Rh-isoimmunized mother having a high antibody titration, associated with foetal death *in utero*.

Immediately upon admission to the hospital, a Lee-White coagulation time was obtained. This specimen finally clotted at the end of seventy-two hours. Whole fresh blood was obtained from the Red Cross unit and heparinized live-donor blood was used as much as possible. Seven donors were bled, and five additional citrated blood samples were cross-matched and made available for the patient. Her blood grouping was Group A Rh-negative. During this time only minimal bleeding was evident, and the University of Minnesota was contacted in an attempt to obtain samples of fibrinogen. Three grams were made available commercially by Cutter Laboratories and were sent to Mankato by Highway Patrol.

As labor progressed, bleeding became more brisk, and towards the end of the first stage of labor, the first fibrinogen supplies were administered to the patient. After administration of three grams of fibrinogen, the patient's blood coagulation time was one and one-half hours by the Lee-White method. Meanwhile, the American Red Cross shipped from Lansing, Michigan, five units of fibrinogen manufactured by them under their fractionation program.

Blood transfusions were started as soon as the bleeding became a problem, i.e., during the second stage of labor. A macerated, stillborn, foetus was delivered spontaneously without laceration of the perineum, during the evening of December 18, 1954. At the time of separation of the placenta bleeding became massive; transfusions were started in both arms and in one leg, and we were still unable to maintain blood pressure

Presented at the annual meeting of the Southern Minnesota Medical Association, New Ulm, September 10, 1956.

within satisfactory limits; the patient rapidly went into shock. Two more units of fibrinogen were made available through Cutter Laboratories from the University of Minnesota and were administered as soon as they arrived. However, at this time there was so much bleeding that the clotting time did not improve. In fact, from its previous one and one-half hour determination, it had risen to two and one-half hours. During the hemorrhagic episode, continuous ecbolics were administered in the form of intravenous pituitary extracts (Pitocin); Vitamin K and ascorbic acid were also administered, and calcium gluconate was given at the rate of one ampule (one-half gram) for every three pints of citrated blood. During the ensuing eight hours, twenty-eight pints of whole blood were given, of which seven were fresh heparinized blood and the remainder citrated bank blood from the American Red Cross. Co-operation by the Red Cross blood bank agencies was remarkable, and shipments were obtained by air from as far away as Washington, D. C.

Bleeding, however, continued because of lack of fibrinogen, and at 5:00 a.m., December 19, 1954, a supracervical hysterectomy was performed because we were no longer able to maintain this patient out of shock. Because of the afibrinogenemia, there was a large amount of oozing from all cuts and peritoneal surfaces. During surgery blood pressure improved from the shock state of 26/0 to 120/65, and the patient was returned to her room in good condition.

Two hours after hysterectomy, the fibrinogen from Lansing, Michigan, arrived. It was administered to the patient with resultant lowering of the coagulation time by the Lee-White method to seven minutes and twenty seconds. The total amount of fibrinogen administered during this second infusion was 4.6 grams, making a total of 10.6 grams. We did a few experiments with blood that had been drawn during her acutely anticoagulant stage. One drop of fibrinogen added to a specimen of that blood caused instant clotting.

Postoperatively, this patient did amazingly well. Examinations of the urine on the following day showed four to five white cells per high power field but no red cells on catheterized specimen. However, there was a considerable quantity of albumin in the urine and that remained present until December 29, eleven days postpartum.

On December 31, a Fishberg urine concentration test was performed, and a specific gravity of 1.024 was obtained. P.S.P. excretion test showed 88 per cent excretion at the end of the third hour, 46 per cent being excreted in the first half hour. Lee-White coagulation times remained within normal limits from December 19 onward, and the patient was discharged the hospital January 3, 1955, the sixteenth hospital day, the fifteenth postpartum day, and the fourteenth postoperative day. The wound had healed *per primam* and follow-up examinations of this patient during the ensuing year and a quarter had been completely normal as far as her pelvis was concerned.

Exactly twelve weeks after her episode of bleeding, the patient was seen with evidence of clinical jaundice,

and a diagnosis of homologous serum jaundice was made. This condition responded well to conservative management, and at the present time this patient is alive and well.

During her entire hospital stay, a total of thirty-eight pints of blood were administered. All of these were Group A Rh-negative and all cross-matched satisfactorily with the patient. All were obtained through the services of the American Red Cross, either as live donors from the Red Cross list, or from bank blood supplied by the Red Cross.

Discussion

In 1950 and in 1951 blood clotting mechanisms as causes of postpartum hemorrhage were reviewed by several groups of workers. All of these people discovered that hemorrhage, being a main cause of maternal mortality in our time, was often associated with defects in the clotting mechanism chemistry. Work by Schneider and his co-workers¹ showed that fibrin alone can be formed and disseminated throughout the circulatory system and that this fibrin can be produced by the induction into the circulation of a trigger substance, i.e., thromboplastin.

Further work by this same group^{2,3} has shown, at least in experimental animals, that crushing the intact placenta can produce this "fibrin embolism" by introducing thromboplastin into the circulation.

The fibrin emboli have been shown to be trapped in the lungs, kidneys, brain, certain mesenteric vessels, and other vital areas of the body. It was postulated by Weber and Paxson⁴ that this defibrination of the blood—in certain cases of abruptio placentae, degeneration of a dead foetus *in utero*, and even in partial abruption with prolonged labors—might be due to the same mechanism of thromboplastin infusion, lowering the fibrinogen content of the blood to a point where clotting defects become obvious.

Kinch and his co-workers⁶ in Toronto studied the fibrinogen levels in normal pregnancy and found that the average level at delivery was 325 milligrams per cent. The range of normality according to duration of gestation showed that early in pregnancy, about the eighteenth week, fibrinogen levels were about 275 milligrams per cent, rising gradually to a maximum, about the thirty-second to thirty-fourth week, to 455 milligrams per cent, and dropping at term to the 325 average. This follows closely the total protein levels which have been investigated by previous

workers. Animal experimentation has shown that amniotic fluid, foetal and placental extracts, are rich in thromboplastin and are capable of reproducing the syndrome of extensive intravascular defibrination. In certain cases of hypofibrinogenemia, especially those associated with intra-uterine death, such as our case, a circulating fibrinolysin has been reported. It has been postulated that this fibrinolysin is present as an attempt by the body to keep the circulation free of clots. However, the entire picture of the etiology of this syndrome remains controversial.⁵

Perhaps the best review article on the management of afibrinogenemia is that by Weber and Paxson in the Philadelphia Symposium Number of the Surgical Clinics of North America, December, 1954.

Conclusions

In our experience, with three cases of hypofibrinogenemia, we have obtained our best results when the condition was diagnosed early, and when treatment was begun prior to the anticipated hemorrhage, i.e., prior to the third stage of labor. We suspect blood clotting defects now with any case of placental abruption, any case of foetal death *in utero*, or any case of unusually prolonged labor, and even in cases of missed abortion. Any physician can perform a Lee-White clotting time determination in his office without complicated equipment. The Fibrindex* Test is a simple

office procedure, which requires only a stop watch and a couple of test tubes.

It would seem, early diagnosis being so important in this type of condition, that failure to do these blood clotting studies in a case of abruption, foetal death *in utero*, and missed abortion, would almost constitute negligence.

It is my belief that hypofibrinogenemia is not a rarity, but that its accurate diagnosis is a rarity. I further feel that with more frequent hematologic studies varying degrees of this condition will be found more and more frequently as time goes on. This may point the way to lowering the maternal mortality rates from hemorrhage, making childbirth even safer than it has been in years past.

THE IOWA JOINT DECLARATION

The Joint Declaration of the Iowa State Medical Society and the Iowa Hospital Association (see Medical Economics section) concerning the practice of Pathology and Radiology in hospitals of that state is a compromise agreement which should result in improved service to the patient. The ideal arrangement, as already expressed in the present laws of both Iowa and Minnesota, can be accomplished only by a physician running the laboratory or radiology department independent of lay hospital administration but controlled in certain aspects by the medical staff. Under these circumstances, he would purchase and own the equipment; hire, pay and discharge the departmental technical personnel; probably rent the space for his practice from the hospital; and charge the patient jointly or separately from the hospital for professional services but always in his own name. This arrangement puts the burden of furnishing the best and most advanced laboratory service completely on the one individual most likely to accomplish the best results—a physician. In the long run of events, this form of private enterprise conducted for a profit by a person trained in the field of medicine was considered in the wisdom of the legislators of many of our states as the most likely to pay the highest dividends to the people of the state.

The Iowa agreement does promote some of the ideals mentioned above but appears to permit the hospitals to assume the major responsibility for the technical personnel and equipment used in the x-ray or laboratory services. A laboratory can be a great success or failure depending upon the quality of either of these aspects of laboratory management. A trial of this mixed responsibility related to two important fundamentals (technical help and equipment) is very likely to begin in the near future in Iowa.

STILL NO CASE FOR POLYGAMY

A man and his wife cannot be convicted of conspiring together since, for many legal pur-

poses, a man and wife are indeed one. This generality probably stems back to earlier than Biblical times, but gained a more formal status as English common law was encased in writing. We accept as axiomatic, then, that such a conspiracy does not exist in the eyes of the law, but now we come to these problems: With how many wives can a man safely conspire? Could a modern Solomon set up a many-splendored conspiracy, say in Arabia; visit the United States as a polygamous unit; and thus thrust into our community a ready-made conspiratorial racket (no matter of what sort) that the law couldn't bring to book? And should this come to pass, would it be better to fight 'em or to join 'em?

We had invested only speculation in exploring this legal loophole when our phantasy exploded. A usually reliable source of legal information handed down the opinion that if all spouses (whether two or two thousand) conspired to commit criminal offenses, they could be convicted of conjoined, and conjugal, "incitement." . . . Now such a simple solution to thwart what looked like a promising way to beat the law left us deflated, though not depressed. This sneaky legal countermove *did* rob us of endless conversational material, but our fears that someone *could* demonstrate an advantage to having a lot of wives are happily unfounded.

WHAT ARE BOOKPLATES?

The term *bookplate* does not convey at first any real idea of what one is, or for what it is used. No wonder some persons think it means a metal plate sunk into the cover of a rare book, and believe that the owner of an elaborate affair such as they imagine it to be must possess vast wealth.

A bookplate is a mark of possession, a small work of art in the general sense of the word, which is pasted into the owner's books, usually at the center of the front cover on the inside, by which

This is the first in a series of editorials on bookplates and their design.

his name is shown and moreover by which the owner tells what he enjoys.

This is done by means of a design of some sort. The design may be conventional or realistic, it may be simple or elaborate, it may be small or large. The simpler the design, the more effective it usually is. Let it represent one central idea such as an out-of-doors spot where you have spent a series of summers or one fleeting week; let it show a corner of your home, or the flower you love best, or if a more formal touch is wished, the family coat of arms.

In the early days of bookplates, about the year 1500 in England, the coat of arms was most generally used on bookplates because this type of design was used to mark practically everything owned by the family. In these days, we are not limited for any such reason and are free to use whatever we choose. People everywhere in the world seem to have found that a bookplate is a charming thing to own and that it will almost invariably bring a book back to its owner.

The oldest known bookplate is estimated to have been made in Germany about 1450, before Columbus discovered America. From Germany, the use spread to England, to France, and finally to all continental countries. In England, the oldest example was that used by Cardinal Wolsey. Its approximate date is 1520. This was a hand-drawn plate and may still be seen in a folio volume belonging to Wolsey. The next oldest English plate (the first engraved plate) was made in 1574 for Sir Nicholas Bacon, affectionately known as "the father of his country and of Sir Francis Bacon."

The earliest French designs were seen about 1574, in Sweden about 1575, in Switzerland in 1607, all before the Mayflower sailed for our shores. Italy followed about 1623. This shows the antiquity of the bookplate and its gradual migration from one country to another.

CLEORA WHEELER

CONFESSIONS OF A HOBBYIST

Stamp Collecting

In 1892, an aunt presented me with a big Scott's Stamp Album. To this day, I can remember eagerly sticking in the first stamp—two-cent rose, United States of America, the issue without the triangles in the corners. The follow-

ing year, the big excitement was the Columbian issue. They were beautiful things, some of them hard to get, even at the post office. How I longed for the \$5-black—portrait of Columbus! Alas, I didn't have five dollars, and it was thirty years before I acquired a copy, for much more than five dollars. Of course I went through the usual small boy's sessions of trading, and buying penny stamps from approval sheets sent out by trusting dealers. Then stamps were laid away for twenty-five years.

In the early twenties, I had another severe attack of the disease. I got out the old albums, discarded copies mauled by small boy handling, and began to study watermarks and perforations. Extravagantly, I bought some occupants for empty spaces. The boarding house where I had been living closed, so I spent one spring term living alone in the Saint Paul Academy building, then far out in the country, and evening after evening I spread out and studied and mounted stamps. Somebody gave me a gunny-sack full of ordinary canceled two-cent stamps, and I examined every single stamp in the vain hope of finding one of those five-centers that were printed red by mistake.

I had one great philatelic thrill. I was in New York, and my friend, Theodore Steinway, invited me to go with him to the Collectors' Club, to see the Lichtenstein collection of British North America. At the head of the table was Mr. Lichtenstein, with an obsequious secretary, who slowly turned the album pages with a pair of small tongs, as we gazed with awe at beautiful, priceless specimens or early Newfoundland and Prince Edward Island stamps, many "on cover."

But one can't collect stamps without spending money, so I had to call a halt. Besides, I wanted hand work, and radio had appeared. The stamps were put away again. Ten years ago, I decided that they were one thing too many in a hobby-ridden house—that if I died and they were of any value, the inheritance tax people might get unpleasant, or some small grandchild would butcher the collection. So, reluctantly, I sold all but a few commemoratives which had been given me. The stamp collection became an aluminum canoe, a slide projector, and part of a Leica camera. I've had more fun out of all three than I ever had with the stamps.

JOHN DEQ. BRIGGS

CALENDAR HISTORY

The first type of calendar of which we have any historical record was called the luni-solar, devised by the Sumerians as early as 3500 B.C. It had twelve lunar months each with twenty-nine and one half days. This made a year of 354 days which was eleven days short of a true solar year. An extra month was added every third year to make up the difference. A variation of this year was adopted by the Jews and is still used as the basis of the Jewish religious calendar.

Along came the Babylonians. These ingenious people drove a stake in the ground to mark the shift of the rising sun and thus record seasonal changes. This calculation of time by seasons was all right for their uncomplicated life, but these early timekeepers were as far off as their predecessors. They, too, had to make an adjustment of eleven days each year. They threw in an extra month every now and then to bring the calendar up to par. This was mighty rough on the farmer and businessmen, but the tax gatherers must have gloated over the chance for extra levies. The Babylonians do get credit for the first system of numbering years, which they introduced in 1747 B.C.

Other experimenters with early calendars were the Mohammedans. They devised a strictly lunar calendar which is still in use today. Since it takes no account of the seasons or the sun, it is continually running fast. About thirty-three Mohammedan years equal thirty-two of our own calendar.

The Chaldeans narrowed the margin of error in about 500 B.C. to a mere half hour a year. They determined the length of the year to be 365 days, six hours, fifteen minutes and forty-one seconds—just thirty minutes too long.

The Egyptians then moved in on this knowledge. They added one day every fourth year making an average year of $365\frac{1}{4}$ days. This calendar was only eleven minutes in error.

Along came the Romans and Julius Caesar went to work on the calendar. His scientists worked out a year of ten months. This included Martius (31 days), Aprilus (29), Maius (31), Junius (29), Quintilis (31), Sextilis (29), September (29), October (31), November (29) and December (29). Later Januarius (29) and Februarius (28) were added.

This calendar accounted for 355 days. But the Romans improvised. A thirteenth month, Mercedonius, was inserted in the middle of Februarius every few years to correct the error. Since this addition was left to the discretion of officials, it was often used for political purposes to lengthen or shorten the term of office for public servants.

Julius Caesar realized the value of the calendar. He also recognized the weakness of the Roman system. To set things right, he boldly added ninety days to the year 46 B.C., thus making it a year of fifteen months and 445 days. This is known as the "Year of Confusion" and provided a field day for tax collectors and turned ordinary business upside down.

But the Romans were still not through monkeying with the calendar. Caesar had conquered Egypt and since Egyptian scientists were astronomically more accurate, Sosigenes, Cleopatra's most famous astronomer, was brought to Rome. He set up what is known as the Julian Calendar. He abandoned the lunar year and took the solar year of $365\frac{1}{4}$ days. The civil year was 365 days, with an additional day added each fourth year.

To honor Caesar's work on the calendar, the month Quintilis was changed to July. Along came Caesar's grand nephew Augustus and changed Sextilis to August to perpetuate his name. To make his month as long as July, he took a day from February and added it to August.

The Julian Calendar was much better than any in use before. It was still eleven minutes fourteen seconds wrong, and these pesky bits of time started piling up over the centuries.

JOSEPH H. SUMMERS
Brown and Bigelow

ALCOHOLISM IN INDUSTRY

Within the past decade, several large corporations have established rehabilitation programs for their problem drinkers. Among such corporations are Consolidated-Edison Company of New York, Eastman Kodak Company, E. I. DuPont de Nemours and Company, Standard Oil Company (New Jersey), and the Allis-Chalmers Manufacturing Company. The results obtained in these rehabilitation programs have been most gratifying.

One rehabilitation program that is being watched with much interest is the Consultation

This is the second in a series of editorials concerning calendar history.

This is the third in a series of four editorials on alcoholism in industry.

Clinic for Alcoholism at the University Hospital of the New York University-Bellevue Medical Center. This clinic was established in 1952 by Consolidated-Edison and several other major Eastern corporations for the treatment of alcoholic employees at a center located outside of the company setting. As reported in the June 30, 1956, issue of the *Journal of the American Medical Association*, 76 per cent of the 180 patients referred to this clinic have been able to remain on their jobs. This figure includes some employees who refused to accept treatment. Of those who accepted treatment, 82 per cent were rehabilitated. The absenteeism rate for employees treated at this clinic dropped from an average of fifteen days per year to an average of five days per year.

In an evaluation of its alcoholism rehabilitation program during a three-year period preceding the formation of this clinic, Consolidated-Edison estimated that the average annual loss to the company due to absenteeism and inefficiency caused by alcoholism was reduced from \$134,250 to \$65,450, a reduction of 49 per cent.

The rehabilitation programs mentioned above have received considerable nationwide publicity. Not so well known are the excellent programs of two national companies with headquarters in Minnesota. One of the outstanding alcoholism rehabilitation programs in the nation is that operated by the Great Northern Railway Company. The Great Northern alcoholism program is directed by two recovered alcoholics, a man and wife operating as a team to provide counseling service for alcoholic employees. Following this, employees are urged to join AA. If the employee is in need of hospitalization because of alcoholism, he is referred to whatever treatment resource seems most appropriate for him.

Since its beginning in 1950, the Great Northern program has been successful in rehabilitating 80 per cent of the alcoholic employees who have taken part in the program. What this means in terms of manpower saved, increased efficiency, and reduced training costs is readily apparent. Since 1953, the Great Northern has had the lowest accident rate per man hours worked of any major railroad in this country. The company feels that this low accident rate is at least in part attributable to the alcoholism rehabilitation program.

Another local alcoholism rehabilitation program of more recent development is that at Minnesota

Mining and Manufacturing Company. This program is conducted by the company's personnel department which makes extensive use of AA and other community social service agencies as referral sources. During the three-year period that the 3M program has been operating, 90 per cent of the alcoholics who have received assistance have been able to remain on their jobs.

Although the primary purpose of the 3M program has been the rehabilitation of alcoholic employees, an additional contribution has been the practical education of the families, clergymen, and supervisors who have taken an active part in the program.

Alcoholics who are employed and still have their homes, families, and community contacts are usually highly motivated to recover from their addiction. This factor accounts for the exceptional success of industrial alcoholism programs. It also emphasizes the importance of additional efforts to rehabilitate the alcoholic at this stage when his chances for recovery are still good.

PATRICK BUTLER, *Chairman
Minnesota Advisory Board
on Problems of Alcoholism*

GOUT: A METABOLIC DISORDER

(Continued from Page 432)

Alkali is given to increase the solubility of the excreted urates. Where sodium restriction is important one must rely largely on a high fluid output to prevent precipitation of uric acid crystals in the urinary tract.

The full co-operation of the patient is essential to the successful management of his gout. If he is adequately instructed as to the nature of his disease, and if he understands the reasons for the above measures, this co-operation usually is given gladly. He can then be followed at intervals of several months each, and his new-found physical well-being will be the best guarantee of his staying close to his gout regimen.

Current information indicates that there are somewhat less than 400,000 active tuberculosis cases in the United States at any one time, approximately one-third of which are hospitalized for tuberculosis, one-third are known cases at home, and one-third are undetected cases. ROBERT J. ANDERSON, M.D., *Public Health Reports*, February, 1956.

President's Letter

BETTER DISTRIBUTION OF PHYSICIANS

A better distribution of physicians throughout Minnesota has been an aim of the Minnesota State Medical Association and of individual physicians for many years. The well-known trek by industry and the professions toward urban centers has left many smaller communities without adequate medical and other professional care. Methods for correcting this maldistribution of physicians and for interesting younger men in the practice of medicine in rural communities have been discussed for years.

Six years ago, the Council of the Minnesota State Medical Association, with the approval of the House of Delegates and with the advice and assistance of the University Relations Committee, inaugurated the Rural Medical Student Scholarship. The implementation and administration of this scholarship plan were vested in the University Relations Committee. Because of the rotating nature of the make-up of the University Relations Committee, a special committee was appointed to guide the plan, with the advice and assistance of the University Relations Committee. This special committee, consisting of Dr. Frank Elias, chairman, of Duluth, Dr. Charles Sheppard, of Hutchinson, and Dr. Edward Simons, of Minneapolis, has administered this plan up to now. According to the report at the inauguration of the scholarship, it has two purposes, namely (1) an effort on the part of organized medicine to solve one of medicine's fundamental problems, the maldistribution of physicians, and (2) the improvement of public relations. The scholarship pays \$1,000 a year for four years. It is awarded on the basis of financial need, residence in a rural region or a town of less than 5,000 population, and an agreement to engage in general practice for five years in a location selected by the student from a list of ten towns of this size furnished by the Minnesota State Medical Association and the Minnesota State Board of Medical Examiners. The Scholarship Committee consists of the Dean of the Medical Sciences of the University of Minnesota, a member of the Council of the Minnesota State Medical Association representing one of the rural districts of the state, a rural editor chosen for that position by the Minnesota Editorial Association, and a qualified farmer chosen by the Minnesota Farm Bureau.

PRESIDENT'S LETTER

The first scholarship was awarded to Richard Engwall of Winthrop, Minnesota, who has completed it and is about to begin his five years of rural practice in Ivanhoe, Minnesota. The following men have been recipients of this scholarship since that first award: Leland Christenson, Marshall, 1954; Myron Doebler, Princeton, 1955; Carl E. Christenson, Stanchfield, 1956; and Vincent Hunt, Anoka, 1957. From now on, there will always be four recipients of the scholarship in the medical school at any one time.

Thus, a distinct effort has been made by the Minnesota State Medical Association toward the solution of this social medical problem.

Industry also has seen the need for an answer to this important question. As a result, the Sears, Roebuck Foundation has embarked on a plan to loan money to physicians to establish units for modern medical practice in communities where physicians are needed. This plan was put into effect in August, 1955, on a national basis, the country being divided into five regions. These regions are North Central, Pacific Coast, Southwestern, Southeastern and Northeastern. A central Sears, Roebuck Foundation office is located in each of these regions, the central office for our region being in Chicago. In the first year of this plan, applications were comparatively few. However, applications have increased steadily with dissemination of information about this plan. So far this year, the flow of applications into the Chicago office has been continuous and somewhat overwhelming; some 100 applications were received in the first three months of 1957. The Medical Advisory Board of Physicians, appointed by the Board of Trustees of the American Medical Association and consisting of two or three physicians from each region, determines the need for physicians in a given region and the advisability of a loan to any given physician. The chief consideration in the granting of these loans is the need of a physician in a given location. The effort of this organization also is to encourage physicians to establish modern medical practices in rural communities. This is another extremely worth-while attempt by a large industry to improve the maldistribution of physicians in this country.

I call attention to these two plans to emphasize that the physicians of Minnesota and the North Central states are making worth-while and dividend-yielding efforts to overcome one of the most basic problems facing the medical profession.

A large, stylized handwritten signature in black ink, reading "J. M. Borgen". The signature is fluid and cursive, with a large loop at the beginning and a long, sweeping tail.

Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

FEDERAL APPROPRIATIONS FOR U. S. PUBLIC HEALTH SERVICE

Appropriations for the new fiscal year commencing July 1, 1957, do not become effective until after the House and the Senate have reached final agreement on all details of the appropriations measures, but the action taken by the House Committee on the following requests can now be reported:

General Assistance to States

This appropriation item consists of a number of activities designed to help support and strengthen preventive health services in states and local communities. The Public Health Service had requested increases totaling \$7 million for these activities of which the House Appropriations Committee approved \$2 million.

Alaska, Grants and Special Studies

The Committee allowed the full budget request of \$2,165,000, an increase of \$995,000 over the amount appropriated last year. This will provide \$1 million to aid the Territory in assuming financial responsibility for an integrated program for the inpatient and outpatient care and treatment of the mentally ill of Alaska. The PHS is presently completing a comprehensive plan for construction of needed hospitals for the mentally ill of Alaska and will be requesting special grants under the Alaska Mental Health Enabling Act which was enacted last year.

Control of Venereal Disease

The Committee allowed the full budget request of \$4,415,000 which includes \$1,700,000 for grants to the states. The PHS reports that the national picture for the first time in eight years showed an increase in the number of infectious syphilis cases reported in the continental United States.

Control of Tuberculosis

The Committee allowed the full budget request of \$7 million which includes \$4.5 million for grants to states for tuberculosis control. An increase was allowed, largely for increased research

into the possible effectiveness of the drug, isoniazid, as a preventive of tuberculosis.

Control of Communicable Diseases

The Committee allowed \$6,200,000 for the work of the Communicable Disease Center, an increase of \$45,000,000 over the amount appropriated last year. This program provides facilities and services for the investigation, prevention and suppression of communicable and preventable diseases other than tuberculosis and venereal diseases.

Sanitary Engineering Activities

This appropriation item provides funds for PHS sanitary engineering activities which deal with environmental factors affecting man's health, including: air pollution, water supply and water pollution control, milk and food sanitation and radiological health.

Grants for Waste Treatment Works

The full \$50 million requested was allowed.

Hospital Construction Grants

The Committee allowed the full budget request of \$44,399,000 which will provide increases for traineeship grants for the advanced education of professional nurses and additional funds for the sixteen hospitals and 123 outpatient facilities operated by the PHS.

Foreign Quarantine Service

The \$3,876,000 allowed for the Foreign Quarantine Service includes an increase of \$203,000 for the control of yellow fever.

Indian Health Activities

For the next fiscal year the Committee allowed \$40 million.

Construction of Health Research Facilities

The House Committee approved the full budget request of \$30 million for the next fiscal year.

Office of the Surgeon General

The Committee allowed \$5,100,000 for the expenses of the divisions of the office of Surgeon

General. Almost half of the increase over last year is necessary to cover expenses for the national health survey program to obtain statistical information on illness and disability in the United States.

U. S. AID TO MEDICAL TRAINING INCREASES

Federal financial support of medical education is on the rise. The Public Health Service plans to inaugurate this summer a new program of research traineeships with every medical and dental school eligible to participate. In addition, the Department of HEW is asking Congress to let the Office of Vocational Rehabilitation finance the full three years of residency training for selected physicians interested in physical medicine and rehabilitation.

The PHS National Institutes of Health will finance the new research traineeships. Eighty-five medical, six osteopathic and forty dental colleges will have one billet each. Students who have completed two years of professional training will be eligible for stipends which will run up to \$3,200 plus \$350 each for dependents. Tenure will be for one year.

NEW HEALTH LEGISLATION IN CONGRESS

Disability Liberalization

Senator Revercomb (R., W. Va.) wants to liberalize broadly the eligibility requirements for payment of social security to disabled workers at age fifty. In introducing two bills on the subject, he stated that "a person must be all but dead to qualify for disability benefits under Public Law 880." Under S. 1811, the Senator would redefine disability. Under S. 1812, he would extend disability coverage to any worker determined to be permanently disabled under his new definition and who has had as little as one-quarter of coverage under social security.

Studies of Social Disability Program

In H. R. 195, Rep. Kelley (D., Pa.) asks for a full investigation of the social security disability program to be conducted by the House Ways and Means Committee.

Federal Workers' Health Insurance

Patterned along the lines of a bill proposed by the International Association of Machinists,

H. R. 6718 provides both basic and major medical coverage for civilian employees of the federal government and their dependents. The government would pay one-half the premium for basic and the full cost of major coverage or an amount equal to \$1.50 biweekly for any employee or \$4 biweekly if coverage includes dependents, whichever is the lesser. Workers would have a choice of plans.

Pre-testing of Food Chemicals

In H. R. 6747, Rep. Oren Harris (D., Ark.) proposes that Congress pass a law requiring that manufacturers of chemical additives to foods establish safety of their products before releasing them for sale.

U. S. Loans to Health Facilities

Senator Humphrey is still urging that federal loans be offered to voluntary nonprofit health insurance plans to help pay for cost of construction and equipment.

Loans Under Hill-Burton Act

Senator Hill (D., Ala.) wants the Hill-Burton hospital construction act modified to authorize loans as well as grants for various types of hospitals and health clinics and centers. Interest would be based on that paid on long-term, U. S. loans and loans would extend for a maximum of forty years.

U. S. Control Over Polio Vaccine

Rep. Green (D., Ore.) proposes that the Secretary of HEW exercise, until December 31, 1957, certain emergency controls over the distribution, sale price and use of poliomyelitis vaccine. The measure states that when there is a temporary shortage of polio vaccine, the Secretary of HEW should be authorized to (1) set priorities by age groups, (2) establish a selling price per unit, and (3) make allocations among the states.

Chiropractors in Compensation Cases

Senator Cooper (R., Ky.) proposes in S. 1650 that the use of chiropractic practitioners be authorized for injured U. S. employees under the Federal Employees Compensation Act. Presently, they are cared for in PHS hospitals if the hospital is conveniently located. Otherwise, care is given by approved private physicians and in private hospitals at government expense. This bill would

make chiropractic practitioners and hospitals eligible to care for such cases.

Pay Increases for VA Proposed

To encourage physicians, dentists and nurses to take up careers in the VA, Rep. Long (D., La.) proposes increases averaging between 10 and 12 per cent from the chief medical director on down. The bill also authorizes practice by optometrists in VA facilities.

Study of Doctor-Shortage Proposed

Rep. Dorn (D., S. C.) in H. R. 6602 proposes a commission to study the "shortage of doctors of medicine in the United States." The twelve-member commission would include physicians, be bi-partisan and be composed half from the Congress and the government and half from private life. The commission would look into the number of medical graduates, medical school admission policies, the number of persons unable to gain admission to medical schools and the extent to which foreign physicians are active in their profession in the United States.

U. S. DELEGATES NAMED TO WHO MEETING AT GENEVA

The tenth annual assembly of the World Health Organization was held May 6-27 at Geneva, Switzerland. Composition of the U. S. official delegation included Dr. Leroy E. Burney, USPHS Surgeon General, Dr. James R. Reuling, AMA trustee, and Dr. H. van Zile Hyde, chief of the international health division in USPHS.

WASHINGTON SELECTED AS MEDICAL LIBRARY SITE

When the regents of the National Library of Medicine assembled in Washington recently, it was to reach unanimous agreement and to make the announcement that Greater Washington will continue to be the home of the collection. It will be on the grounds of the National Institute of Health in suburban Bethesda, Maryland, about 12 miles northwest of the White House. Funds must still be obtained from Congress for the new building. The main obstacle now is the reluctance of the administration to ask Congress for building funds at a time when economy is being stressed, particularly for undertakings not in the "urgent" class.

NATIONAL HEALTH SURVEY BEGUN

Early in May, the Census Bureau launched the National Health Survey. Door-to-door canvassing will be conducted in every state. Interviewers will ask twenty-six questions, plus full details of recent illnesses, accidental injuries, confinements and surgical operations. The national sampling will cover 3,000 urban and rural households monthly for an indefinite period. Preliminary findings are expected to be published before the close of this year. Special statistical compilations will be made for the eight metropolitan areas which had more than 2,000,000 population in 1950: New York, Chicago, Los Angeles, Philadelphia, Detroit, San Francisco, Pittsburgh, and Boston.

Each adult in every household polled is to be checked for history of twenty-six chronic conditions; orthopedic, visual, hearing and other permanent impairments; time missed from work or housekeeping as a result of illness or invalidism. Residents will be asked when they last saw a physician, a dentist and, as an inpatient, the inside of a hospital.

The PHS for whom the Census Bureau is conducting the survey defines "Doctor" as a physician holding the degree, M.D. or D.O. In instances where the interviews disclose that he obtained diagnosis or treatment from someone other than a Doctor of Medicine or Doctor of Osteopathy, such attention will not be recorded as medical care. No information whatever will be sought on consumer costs of medical or dental treatment, hospitalization or health insurance.

ADMINISTRATION ENDORSES BARBITURATES CONTROL BILL

The Administration recently gave its approval to bills controlling the manufacture, distribution and possession of barbiturates and amphetamines. The House Interstate and Foreign Commerce health subcommittee held a one-day session on these bills just before its Easter recess. Reports of this session reveal that proposals for record-keeping and reporting would not apply to the medical profession; cutting down addiction will require more co-operation with the states, not just federal efforts; cost of the law during its first year would be \$500.00.

JOINT DECLARATION ON PHYSICIAN-HOSPITAL RELATIONS

1. The ownership and maintenance of the laboratory and x-ray facilities and the operation of same under this joint declaration is a proper function of a hospital.

2. Pathology and radiology services performed in hospitals are the product of the joint contribution of hospitals, doctors and technicians but these services constitute medical services which must be performed by or under the direction and supervision of a doctor, and no hospital shall have the right, directly or indirectly, to direct, control or interfere with the professional medical arts and duties of the doctor in charge of the pathology or radiology facilities or of the technicians under his supervision.

3. Each hospital should arrange for such services and for the direction and supervision of its pathology or radiology department by entering into an oral or written agreement with a doctor who is a member of or acceptable to the hospital medical staff. Such doctor may or may not be a specialist. The laboratory may be supervised and directed by a qualified member of the staff and specific services may be referred to a specialist, or the specialist may also direct and supervise the laboratory as may be desired. Any contract so entered into shall be in accordance with the principles stated herein.

4. Technicians and other personnel (not including doctors) in pathology or radiology departments, shall (unless the department is leased *or unless the hospital and doctor mutually agree otherwise*) be employes of the hospital, subject to the rules and regulations of the hospital applicable to employes generally, but under the direction and supervision of the doctor in charge of the Department as set forth elsewhere in this Declaration.

5. The doctors and hospitals shall mutually agree upon the employment of any technicians necessary for the proper operation of said Department and no technicians shall be dismissed from said employment without the mutual consent of the parties provided, however, that in the event the hospital and doctor are unable to mutually agree upon the hiring or discharge or disciplining of any employe of said Departments, the matter shall be promptly submitted to the joint conference committee.

Italicized portions of this agreement are amendments approved by the joint committee on November 12, 1956.

This physician-hospital agreement was developed and approved November 8, 1956, by a joint committee of hospital trustees and Medical Society representatives. As amended, it was ratified by the Board of Trustees of the Iowa Hospital Association on November 14, 1956, and by the Executive Council of the Iowa State Medical Society on November 15, 1956.

6. The contract between the hospital and doctor in charge of the laboratory or x-ray facilities may contain any provision for compensation of each upon which they mutually agree, provided, however, that no contract shall be entered into which in any way creates the relationship of employer and employe between the hospital and the doctor, and a percentage arrangement is not and shall not be construed to be unprofessional conduct on the part of the physician or in violation of the statutes of the State of Iowa upon the part of the hospitals.

7. The hospital admission agreement signed by the patient or his legal representative shall contain the following statement:

"Pathology and radiology services are medical services performed or supervised by physicians, and the personnel and facilities are furnished by the hospital for said services. Charges for such services are collected, however, by the hospital on behalf of said doctors pursuant to an agreement between said physicians and the hospital, and from said charges I consent that an agreed sum will be retained by the hospital in accordance with an existing agreement between the doctor and the hospital."

8. The hospital bill shall properly include the charges for pathology and radiology services as long as the name of the doctor is stated and it fairly appears that the charge is for medical services.

The said hospital bill shall also contain a statement substantially in the following form:

"The pathology and radiology charges are for medical services rendered by or under the direction of the doctor listed above and are collected by the hospital on behalf of the doctor, from which charges an agreed sum will be retained by the hospital in accordance with an existing agreement to which retention you consented at the time of your admission to the hospital."

9. All fees to be charged by the physicians for pathology and radiology services shall be mutually agreed upon by the hospital and the doctor. In the event dispute shall arise between the parties the matter shall be submitted for judgment to the Joint Conference Committee.

10. Fees for radiology and pathology services must be paid for as medical and not hospital services. In all cases this requires payment by "Blue Shield" (Iowa Medical Service) and not by "Blue Cross" (Hospital Service of Iowa).

11. Nothing in these principles is intended or should affect in any way that obligation of public hospitals under Chapter 347 or 380 of the Code of Iowa (1954), as well as the State Hospital at Iowa City, to provide medical treatment for indigent persons or tuberculosis patients as provided in Chapter 254 and Chapter 255 of the Code wherein medical treatment is to be provided by

hospitals of that category to patients of certain entitlement, nor to the operation by the State of mental or other hospitals authorized by law.

12. Whenever used herein the term:

- (a) "Hospital" shall include all hospitals licensed under Chapter 135B of the Code of Iowa (1954);
- (b) "Doctor" shall mean any person licensed to practice medicine and surgery under the provisions of Chapters 147 and 148 of the Code of Iowa (1954);
- (c) "Technician" shall mean either technician or technologists.
- (d) "Joint Conference Committee" shall mean the "Joint Conference Committee" as required by the Joint Commission on Accreditation of Hospitals.
- (e) "'Employes' as used the first time it appears in Paragraph 4 hereof, and 'employment' as used in Paragraph 5 hereof, shall include and pertain to members of the religious order operating the hospital even though the relationship of employer and employe does not exist between such members and the hospital."

13. This Joint Declaration shall be submitted to the Iowa State Medical Society and to the Iowa Hospital Association for approval on November 15, 1956, and it is recommended that this Joint Declaration be implemented by both organizations in a spirit of cooperation as to the pending Supreme Court appeal and in all other respects and that joint action by legislation be undertaken to legalize the principles herein stated wherever necessary.

Agreed to and signed this 8th day of November, 1956.

CANCER CURES AND DEATH RATE

"It is a paradox that with the immense knowledge at hand, the death rate from cancer continues to mount—although the number of cures of cancer is increasing," Dr. Grant H. Beckstrand, radiation therapist from Long Beach, California has reported.

His comments appeared in the March, 1957 issue of the *American Journal of Roentgenology, Radium Therapy and Nuclear Medicine*.

In his article, Dr. Beckstrand pointed out that much progress in understanding of the disease has been made, and financial support of cancer research has increased a hundred times over the money expended twenty-five years ago.

"The amount of money available," he added, however, "should be greatly increased, to direct intelligent Americans into cancer research."

Other highlights from Dr. Beckstrand's article: The cancer processes are as great as those of life itself. Indeed, in battling these processes, the human body, its normal physiology and psychology all must be weighed constantly.

One fact is clear: the cancer patient and not the cancer alone must be treated.

SOME NEGLECTED PRACTICAL POINTS IN ALLERGY

(Continued from Page 409)

supplied by the synthetic vitamins. Citrus fruit juices are not usually started until the child is eight to twelve months of age. As part of routine care (whether or not there is a family history of allergy), the mother is advised to rotate and diversify the child's diet, by giving different foods of the same family each day. I have not started cereal feeding with the mixed cereals, which usually contain wheat and corn, two very common allergens, but have had the mother alternate the single cereals, oatmeal, rice and barley. Such rotation is practiced with other foods as much as possible. In addition, where there is an allergic history, the parents are advised against having dogs and cats as pets, and feather pillows should be replaced by foam rubber or dacron pillows.

While an exact statistical analysis has not been possible, it seems the above-mentioned approach has been of considerable help in preventing the development of food sensitivities.

Summary

Allergic disease can be best diagnosed by history, physical examination and special allergic tests. The individual food tests are of much greater help than the skin test in determining food sensitivities. Allergic disease is managed best by avoidance of the offending allergens, hyposensitization when avoidance is not possible, and symptomatic therapy. Suggestions for symptomatic therapy are given.

The finding that 7.2 per cent of the patients in a tuberculosis sanatorium have "serologically proved" histoplasmosis and that the actual presence of the microorganism was demonstrated in 33 per cent of the cases is indeed remarkable. It certainly calls for very serious consideration of the importance of histoplasmosis in tuberculosis sanatoriums.—MICHAEL L. FURCOLOW and CHARLES A. BRASHER, M.D., *Am. Rev. Tuberc.*, May, 1956.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Bldg., Saint Paul 2, Minnesota

F. H. Magney, M.D., Secretary

PHYSICIANS LICENSED FEBRUARY 10, 1956

January, 1956, Examination

SAINT PAUL BARBER SENTENCED FOR ILLEGAL SALE OF MEDICINE

Re: State of Minnesota vs. Thomas A. Medella

On April 26, 1957, Thomas A. Medella, seventy-six, 437 University Avenue, Saint Paul, was sentenced by the Hon. Archie L. Gingold, Judge of Saint Paul Municipal Court, to a term of thirty days in the Saint Paul Workhouse after being found guilty of the illegal sale of medicine. The complaint against the defendant, which was signed by a representative of the Minnesota State Board of Medical Examiners, specifically charged Medella with wilfully selling at retail a medicine "helpful for eczema, skin itch, old sores, pile sufferers, athlete's foot and dandruff" in a place other than a pharmacy. After telling the defendant that the purpose of this law was to protect the public and that his actions had been detrimental to the reputation of the whole barbering profession, Judge Gingold suspended Medella's sentence for a period of one year on condition that he be a law abiding citizen. Medella testified at the trial that he had attended a barber college in Rome, Italy, for three years and that he came to Saint Paul in 1911.

The evidence in the case indicated that when a Saint Paul man was having his hair cut at the defendant's barber shop at 511 Wabasha Street on April 8, 1957, Medella displayed a bottle of "Cahcetula" and stated that it was a medicine made from a tree that grows in Italy. After examining the customer's scalp, Medella told him that he had dandruff and that medical science had found that dandruff was one of the chief causes of cancer. Medella then proceeded to give the customer a scalp massage, notwithstanding the customer's protest, by using a bottle of "Cahcetula," the label on which represented that it was manufactured by "Thos. Medella Co." of Saint Paul and further, that the preparation was helpful for the six conditions listed above. The label also indicated that the price for an eight-ounce bottle of the red liquid was \$1.50.

After the customer had received a haircut and scalp massage, he handed Medella a ten dollar bill and received back from him \$3.50 and a bottle of "Cahcetula." The customer protested this and, after the ensuing argument, Medella took back the bottle and returned two dollars more to the customer. However, when the matter was reported to the State Board of Barber Examiners, Medella was persuaded to refund an additional two dollars to the customer and to give him back the bottle of "Cahcetula." When the case was

brought to the attention of the Minnesota State Board of Medical Examiners, a criminal complaint was immediately filed against the defendant. On May 10, 1957, the Saint Paul City Council, after a hearing, revoked Medella's barber shop license because of his conviction in Saint Paul Municipal Court of the offense described above.

SAINT PAUL MAN SENTENCED FOR ABORTION ATTEMPT

Re: State of Minnesota vs. Frank J. Urman

On April 30, 1957, Frank J. Urman, forty-six, 301 Walnut Street, Saint Paul, was sentenced by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, to a term of not to exceed two years in the State Reformatory for Men at St. Cloud, pursuant to his plea of guilty to an information charging him with the crime of attempted abortion, which he had previously entered before Judge Hall on March 27, 1957. However, Judge Hall then stayed the execution of the sentence for a period of two years and placed the defendant on probation during that time with the Hennepin County Probation Office. At the same time, after dismissing a similar charge which had been placed against the defendant's mother in connection with the case, Judge Hall cited her age, physical condition and previous good record, as his reasons for doing so.

Urman was arrested in a Minneapolis hotel room on March 20, 1957, after the Minneapolis Police Department had received information that an abortion was to be performed there. The investigation which was conducted in connection with the case revealed that a thirty-five-year-old Fargo, North Dakota, housewife had paid Urman \$150.00 to have an abortion performed by his mother. The evidence also indicated that the Fargo woman, while riding in a taxicab from Saint Paul to Minneapolis, had made inquiry of the driver as to whether he knew where she could obtain an abortion. The driver made a notation of the woman's name and the place where she was staying in Minneapolis, and she was subsequently contacted there by Urman, who was employed as a dispatcher by a Saint Paul Cab company. The Fargo woman was lying on the bed waiting to be aborted when the police entered the Minneapolis hotel room, but since the actual performing of the abortion had not yet been started, Urman was not charged with the crime of abortion but with the lesser offense of attempted abortion.

Meetings and Announcements

NATIONAL

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

American Association of Rehabilitation Therapists; Association for Physical and Mental Rehabilitation; Association of Medical Directors and Co-ordinators, Chicago, July 7-12.

First American Congress on Legal Medicine and Law-Science Problems (replacing the annual Chicago Law-Science Short Course), Hotel Morrison, Chicago, Illinois, July 8-13 and 15-20, 1957. Conducted by the Law-Science Institute of the Schools of Law and Medicine, The University of Texas, Austin, Texas. Hubert Winston Smith, M.D., Professor of Law and Legal Medicine, Director, the Law-Science Institute, University of Texas (also Director, The First American Congress of Legal Medicine and Law-Science Problems).

Midwest Cardiac Conference, Iowa State University Hospitals, Iowa City, Iowa, October 3-5, 1957.

Ninth Postgraduate Assembly in Endocrinology and Metabolism, Medical College of Georgia, October 21-25, 1957.

Symposium on Tuberculosis and Other Chronic Pulmonary Diseases, Saranac Lake, New York, July 8-12, 1957. Sponsored by the American Trudeau Society, Saranac Medical Society, Adirondack Counties Chapter of the New York State Academy of General Practice. Write P. O. Box 11, Saranac Lake, New York.

INTERNATIONAL

Congress of International Society for Cell Biology, St. Andrews, Fife, Scotland, August 28-September 3. Prof. H. G. Callan, Bell Pettigrew Museum, The University, St. Andrews, Fife, Scotland.

Congress of International Society of Orthopedic Surgery and Traumatology, Barcelona, Spain, September 16-21. International Society of Orthopedic Surgery and Traumatology, 34 rue Montoyer, Brussels, Belgium.

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. DeJardin, 141 rue Belliard, Brussels, Belgium.

Fourth International Poliomyelitis Conference, Geneva, Switzerland, July 8-12. Registration deadline, April 1. Fourth International Poliomyelitis Conference, Secretariat, Hotel du Rhone, Geneva, Switzerland.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

International Symposium on Medical-Social Aspects of Senile Nervous Diseases, Venice, Italy, July 20-21. Secretariate, Viale Morgagni 85, Firenze, Italy.

Neuroradiologic Symposium, Brussels, Belgium, July 21-28. Professor Melot, Hôpital Universitaire St. Pierre, Brussels, Belgium.

Pan-Pacific Surgical Association, seventh congress, Honolulu, Hawaii, November 14-22, 1957. Write Dr. F. J. Pinkerton, director-general of the Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, Hawaii.

CONGRESS OF LEGAL MEDICINE AND LAW-SCIENCE PROBLEMS

The First American Congress of Legal Medicine and Law-Science Problems will be conducted by the Law-Science Institute of Austin, Texas, at the Hotel Morrison, Chicago, Illinois, from Monday, July 8, to Saturday, July 13, inclusive, and Monday, July 15 to Saturday, July 20, 1957, inclusive, with the aid and co-operation of the Law-Science Academy of America and the Law-Science Foundation of America.

In Memoriam

PAUL I. CARMAN

Dr. Paul I. Carman, former Saint Paul physician, died March 25, 1957, in Cincinnati, Ohio. He was sixty-seven years old.

Dr. Carman, an eye, ear, nose and throat specialist, retired from practice in 1940.

He had been a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Blanche, and an uncle, the Reverend Marcus J. Simpson, Portland, Connecticut.

W. Z. FLOWER

Dr. W. Z. Flower, pioneer physician of Gibbon, Minnesota, died April 23, 1957. He was ninety-five years old.

Dr. Flower practiced medicine for almost sixty years, forty of which he spent in Gibbon. At the time of his death, he was living in Minneapolis with a daughter.

In 1952 the citizens of his home town paid tribute to him with a "Dr. Flower Day."

Dr. Flower graduated from the University of Illinois, Chicago, in 1887. He spent some years practicing in Minneapolis—from 1921 to 1941.

He had been a member of the Camp Release Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his daughter, Mrs. Leroy Muldner, Mound, Minnesota; seven sons, Don and Franklin, Los Angeles; Oliver, Detroit; Hiram, James, Harold and Clarence, Minneapolis, five grandchildren and one great-grandchild.

CLAUDE B. LEWIS

Dr. Claude B. Lewis, long-time head surgeon at St. Cloud Hospital and brother of the late author, Sinclair Lewis, died April 20, 1957. He was seventy-eight years old.

Born in Ironton, Wisconsin, Dr. Lewis moved at an early age to Sauk Center, where his father practiced medicine for many years. He attended the University of Minnesota and graduated from Rush Medical College, Chicago, in 1903.

Dr. Lewis began practicing medicine in St. Cloud in February, 1905, and continued there until he went into partial retirement in 1949. He was primarily responsible for the establishment of the St. Cloud School for Nurses.

During the first years of his half century of practice, Dr. Lewis was associated with Dr. J. B. Dunn. Then for some years he worked with Dr. M. J. Kern and later for many years he was a member of the Lewis-Stangl Clinic in association with Dr. P. E. Stangl, Dr. Fred H. Stangl, and Dr. William L. Freeman. After his partial retirement, he maintained an office with Dr. W. B. Richardson and C. S. Donaldson. At this time, he also traveled extensively with his author-

brother. Dr. Lewis wrote extensive descriptions of his many trips all over the world and gave colorful lectures.

Dr. Lewis was a charter member and former president of the St. Cloud Kiwanis Club and a member of the First Presbyterian Church. He also belonged to the Stearns-Benton County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a member of the State Association's "50 Club" group. Dr. Lewis belonged to Sigma Xi, honorary science society, and Alpha Kappa Kappa medical fraternity.

Survivors include his wife, Helen; a son, Freeman, New York City; two daughters, Virginia, San Francisco, and Mrs. Robert Agrell, Excelsior, Minnesota.

MERRIAM GERARD FREDRICKS

Dr. Merriam G. Fredricks, Duluth dermatologist, died May 1, 1957. He was forty-four years old.

A native of Crookston, Minnesota, Dr. Fredricks received his medical education at the University of Minnesota. He interned at Milwaukee County Hospital, Wauwatosa, Wisconsin, and received his master of science degree in dermatology and syphilology from the University of Minnesota.

At the time of his death, Dr. Fredricks was on the staff of the Duluth Clinic. He was also on the staffs of Minneapolis General and University Hospitals, Minneapolis.

He had been a member of the Hennepin County Medical Society, the St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association.

PAUL D. McCARTY

Dr. Paul D. McCarty died suddenly at his home on Birch Point, Lake Vermillion, Tower, Minnesota, April 24, 1957. He was seventy-three years old.

Dr. McCarty was born in Rolling Prairie, Indiana. He graduated from Rush Medical College, Chicago, and interned at Cook County Hospital. He was a pioneer physician in the northern Minnesota mining country, as he settled in the Biwabik district in March, 1908. He was practicing at Babbitt during the first experimental taconite development from 1920 to 1924. From 1924 to 1944, he practiced in Ely, Minnesota. He was then incapacitated by a stroke and retired from active practice.

Dr. McCarty was a member of the St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Frances; a daughter, Mrs. Harold A. Balsley, Madison, Wisconsin; two sons, Paul D., Jr., Silver Bay, Minnesota, and Eugene F., Summerville, South Carolina, and seven grandchildren.

Woman's Auxiliary

NATIONAL CONVENTION HELD IN NEW YORK

The Woman's Auxiliary to the American Medical Association held its thirty-fourth annual convention in New York City, June 3-7. Minnesota was honored to be represented by its former state president and past national president, Mrs. Harold F. Wahlquist, Minneapolis, who installed the new national officers at the morning session, Thursday, June 6.

Headquarters for the sessions was the Hotel Roosevelt. Minnesota delegates attending the meeting attended a variety of worthwhile and interesting sessions. Included among the guest speakers were AMA President Dwight H. Murray, President-elect David B. Allman, Dr. Howard A. Rusk, chairman of the department of physical medicine and rehabilitation of New York University Bellevue Medical Center, and Professor Allen R. Foley, professor of history, Dartmouth College, whose topic was "Vermont Humor."

NEWS FROM THE COUNTY AUXILIARIES

Freeborn County

The Freeborn County medical auxiliary elected new officers at a dinner meeting at the Hotel Albert in Albert Lea, April 18. Mrs. A. G. Sherman was elected president; Mrs. Darwin Holian, vice president, and Mrs. Charles Wilcox, secretary-treasurer. All are from Albert Lea.

Hennepin County

The annual Cotton Carousel sponsored by the Hennepin County group was an outstanding event again this year. It was held two days, April 24 and 25, in Dayton's Sky Room, Minneapolis. Proceeds went to sixteen charitable organizations throughout the city and state. Mrs. Russell Lindgren and Mrs. Harold Noran, Minneapolis, were co-chairmen.

Mower County

Mrs. L. P. Howell, president of the state auxiliary, and Mrs. H. F. Polley, regional adviser, both of Rochester, were guests at a recent meeting of the Mower County Auxiliary. Mrs. Wallace Anderson was hostess. Mrs. Howell told of her work as state president and a movie on AMEF was presented.

Ramsey County

A colorful fashion festival was held March 22 in the Continental Room of the Hotel Saint Paul. Sponsored by the Ramsey County Auxiliary, the affair featured fashions by Rosen-Engelson, Saint Paul. Schiek's Sextet entertained during the intermission. Mrs. H. F. Schroeckenstein was general chairman.

On March 25, a "What's Cooking in Our Town"

workshop was held at the Hotel Lowry. It was sponsored by the Inter-Club Council, of which the Ramsey County Auxiliary is a member. Problems discussed included aging citizens, civic development, health, and educational television.

Winona County

Mrs. Carl Heise was elected president of the Winona County Auxiliary at a recent business session which followed a joint dinner with the medical society at the Hotel Winona. She succeeds Mrs. R. H. Wilson.

Other officers named were Mrs. John Keyes, vice president; Mrs. Warren Haesly, secretary; Mrs. Roger Hartwich, corresponding secretary, and Mrs. Charles Rogers, treasurer. The group also voted to donate a sum to AMEF and made plans to participate in the "Magazines for Friendship" project. On April 18, the group met to sew at Lake Park Lodge. Mrs. Howard Satterlee, Lewiston, and Mrs. P. A. Mattison were hostesses.

IN MEMORIAM

HERMAN J. WOLFF

Dr. Herman J. Wolff, Saint Paul physician, died April 19, 1957. He was fifty years old.

Dr. Wolff graduated from the University of Minnesota medical school in 1930 and later was a graduate fellow of the Mayo Foundation at the University. He was an associate professor of internal medicine at the University of Minnesota, a fellow of the American College of Physicians, a diplomate of the American Board of Internal Medicine, president-elect of the Minnesota Pathologic Society, and past chief of internal medicine at Miller Hospital, Saint Paul.

He was also on the staffs of St. Joseph's, St. John's, St. Luke's and Ancker Hospitals, Saint Paul.

A member of the Ramsey County Medical Society, he also belonged to the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Ruth; two sons, Richard and John; a daughter, Elizabeth, and a brother, Benno, all of Saint Paul.

The most unfortunate feature of tuberculosis in elderly persons is that it usually has no distinctive symptom. The cough, sputum, dyspnea, slight dyspepsia and a general feeling of lassitude are all put down to increasing years. It is only when sudden pain or hemoptysis occurs that the patient becomes alarmed and seeks advice. It is then that advanced, old-standing disease is found, and the damage done from the wide distribution of tubercle bacilli from this focus of infection over a number of years can be visualized.—F. R. G. HEAF, M.D., *J. Royal Inst. Pub. Health and Hygiene*, November, 1955.

FOR POSITIVE DIURESIS

ROLICTON[®]

Brand of Amisometradine

- oral b.i.d. dosage
- continuous control of edema

The new, highly effective oral diuretic, Rolicton, greatly simplifies the task of maintaining an edema-free state in the patient with congestive heart failure. Rolicton meets the criteria for a dependable diuretic: continuous effectiveness, oral administration and clinical safety.

In extensive clinical studies the diuretic response clearly indicates that a majority of patients can be kept edema-free with Rolicton. In these investigations it was noted that side reactions were uncommon. When they did occur they were usually mild.

In most edematous patients Rolicton may be employed as the sole diuretic agent. When used adjunctively in severe cases, Rolicton is also valuable in eliminating the "peaks and valleys" associated with the parenteral administration of mercurial diuretics.

One tablet of Rolicton b.i.d., after meals, is usually adequate for maintenance therapy after the first day's dosage of four tablets. Some patients respond well to one tablet daily. G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

SEARLE

General Interest

Dr. Herschel Cope, who recently completed his three-year residency in obstetrics and gynecology at the University of Minnesota Hospitals, has rejoined the staff of the Lenont-Peterson Clinic in Virginia.

* * *

Newly elected staff officers of the Virginia Municipal Hospital include **Dr. David Richter**, chief-of-staff, **Dr. Herschel Cope**, vice chief-of-staff, and **Dr. J. J. McKenna**, secretary.

* * *

Dr. Bradley Ruth has joined the anesthesiology staff of St. Luke's Hospital, Duluth.

* * *

Dr. M. M. Fifield, Duluth, was recently certified by the American Board of Urology.

* * *

Dr. A. J. Henderson, Ramsey County Coroner, gave a talk at the monthly meeting of the St. Croix-Pierce County (Wisconsin) Medical Society, at Richmond, Wisconsin, Tuesday, April 16, 1957, on the subject, "Work and Duties of a County Coroner."

* * *

The Olmsted Medical Group, Rochester, has moved to new quarters in Miracle Mile where complete x-ray and laboratory facilities are available. **Drs. Harold A. Wente** and **J. R. Flanary** say the move was necessary to relieve crowded conditions in their previous quarters.

* * *

Among the visiting faculty members at the institute on mental retardation held at the University of Minnesota Center for Retardation, April 11 and 12, was **Dr. Haddow M. Keith**, of the Section of Pediatrics, Mayo Clinic, Rochester. The institute, conducted mainly for Minnesota public health nurses, was jointly sponsored by the Minnesota Department of Health.

* * *

Dr. Leo G. Rigler, head of the University of Minnesota department of radiology, has resigned, effective June 30, to become consultant at Cedars of Lebanon Hospital in Los Angeles, California. He will also teach on a part-time basis, at the University of California Medical School in Los Angeles. **Dr. Rigler** came to the University of Minnesota in 1927, where he served successively as associate professor, professor, and finally, since 1935, chief of the department of radiology.

* * *

Dr. Edgar V. Allen, internist of the Mayo Clinic and professor of medicine in the Mayo Foundation, who is also president of the American Heart Association, spoke on April 10 at the annual dinner of the Iowa Heart Association in Des Moines. His subject was "The Research Program of The American Heart Association."

Dr. Allan spoke before the Los Angeles County Heart Association in Los Angeles, California, on May 15 on "The Importance of Research." On May 17 he spoke to members of the California Heart Association at San

Diego on "The American Heart Association: Its Aims and Accomplishments."

Dr. Allen was in New York City on May 20, 21 and 22 to attend meetings of the budget committee, the policy committee and the nominating committee of the American Heart Association in his capacity as president of the organization.

* * *

The recently incorporated Minnesota Epilepsy League has announced the appointment of the following members to its medical advisory board: **Dr. A. B. Baker**, director of the division of neurology, and **Dr. Frank Morrell**, head of the adult seizure clinic, University of Minnesota Medical School; **Dr. V. Richard Zarling**, neurologist, Minneapolis; **Dr. Paul Ellwood, Jr.**, department of pediatrics, University of Minnesota Hospitals; **Dr. W. R. Heilig**, St. Paul pediatrician; and **Dr. George L. Wadsworth**, superintendent of the Cambridge State School and Hospital. Two more medical representatives from the Rochester and Duluth areas, as well as lay members of the board, are still to be appointed.

* * *

Dr. Philip S. Hench, Nobel prize-winning physician from the Mayo Clinic, flew to Sweden on April 12, where he participated in a Symposium on Rheumatic Diseases in Stockholm, April 14-18, sponsored by the Karolinska Institute. **Dr. Hench** spoke on "The Therapeutic and Physiological Effects of the Use of Cortisone in Rheumatic Disease" at a joint meeting of the Symposium and the Swedish Society of Medicine, and he also spoke before a panel on "Psychogenic Rheumatism: Social and Economic Importance."

* * *

Dr. David S. Berkman, a native of Rochester, has joined the staff of the Olmsted Medical Group, returning to Rochester after nine years of practice of internal medicine in Rapid City, South Dakota. **Dr. Berkman** received his M.D. degree in 1944 from the Medical College of Virginia, Richmond, Virginia, and completed his fellowship in medicine at the Mayo Foundation in Rochester.

* * *

Dr. Clyde A. Undine, Minneapolis, attended the annual convention of the American College of Physicians in Boston in early April. While in the east he also visited clinics in New York City and Jersey City.

* * *

On April 8, 1957, the National Ataxia Foundation, a nonprofit corporation to raise funds for research and treatment of ataxia, was organized in Minneapolis. The prime mover in this organization is **Dr. John Schut**, a specialist in neurology and psychiatry, and himself a victim of the disease. He estimates that there are between 10,000 and 20,000 victims of this hereditary disease in the nation. One of the first projects of the foundation will be financed with a \$19,000 grant from the federal government. This money will be allo-

cated over the next two years to the Minneapolis War Memorial Blood Bank for a study of blood groups of ataxia victims.

* * *

The Minnesota Society of Neurology and Psychiatry met at the Mayo Clinic in Rochester, May 4, 1957. Dr. J. G. Rushton spoke on "One hundred fifty years of Nonsurgical Treatment of Trigeminal Neuralgia." Drs. R. W. Hollenhorst, Harold A. Stein, H. M. Keith, and C. S. MacCarty discussed "Subdural Hematoma and Subarachnoid Hemorrhage among Infants and Children." A motion picture on "Periodic Movement Disorders" was presented by Dr. J. R. Brown. "Psychogenic Determinants in Murder: A Study of Six First Degree Murderers and Their Parents" by Drs. G. M. Duncan, S. H. Frazier, E. M. Litin, A. M. Johnson, and Alfred Barron, and "Total Hemispherectomy in the Monkey" by Drs. R. J. White and C. S. MacCarty rounded out the morning program. Following luncheon, Dr. D. W. Mulder reviewed the "History of Lake Pepin: 1650-1850."

* * *

Dr. Gustavus A. Peters of the Mayo Clinic was appointed to the Rochester Board of Public Health and Welfare to fill out the unexpired term of Dr. John A. Paulson.

* * *

After forty-two years of service as professor of public health at the University of Minnesota, Dr. J. A. Myers retired at the close of the school year in June. Five Mayo Foundation faculty members also retired at that time: Dr. Arlie R. Barnes, professor of medicine, with thirty-seven years' service; Dr. Winchell M. Craig, professor of neurosurgery, and Dr. Duncan M. Masson, assistant professor of medicine, each with thirty-six years of service; Dr. Austin C. Davis, assistant professor of medicine, twenty-nine years; and Dr. Robert E. Fricke, associate professor of radiology, twenty-eight years.

* * *

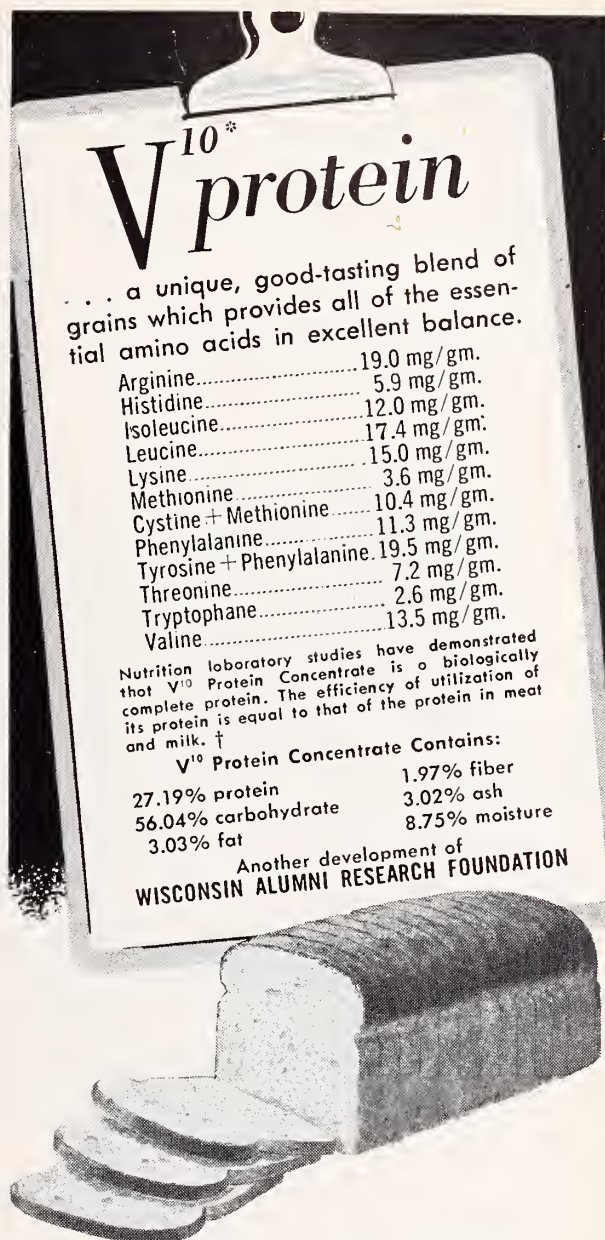

Five Minnesota scientists and physicians have been awarded \$47,100 for heart and blood vessel research, according to a statement from Dr. Robert L. Parker, Rochester, president of the Minnesota Heart Association. The recipients are Dr. Newton Birkhead, Mayo Foundation, and Drs. Richard A. DeWall, Robert L. Vernier, Victor Lorber, and Alan P. Thal, all of the University of Minnesota. This grant is part of a joint support program of the American and Minnesota Heart Associations, under which 155 medical scientists in twenty-nine states will share in \$977,000 worth of awards.

* * *

As part of the observance of Mental Health Week, a workshop was held on May 1 at the Woman's Club, Minneapolis. Dr. Dale C. Cameron, medical director of the Minnesota department of public welfare, was the main speaker; his subject "Things You Should Know About the No. 1 Health Problem."

* * *

Dr. Richard Sartor, a native of Chisholm, who has been practicing in Minneapolis with Dr. Peter Schultz,

V¹⁰ protein

... a unique, good-tasting blend of grains which provides all of the essential amino acids in excellent balance.

Arginine.....	19.0 mg/gm.
Histidine.....	5.9 mg/gm.
Isoleucine.....	12.0 mg/gm.
Leucine.....	17.4 mg/gm.
Lysine.....	15.0 mg/gm.
Methionine.....	3.6 mg/gm.
Cystine + Methionine.....	10.4 mg/gm.
Phenylalanine.....	11.3 mg/gm.
Tyrosine + Phenylalanine.....	19.5 mg/gm.
Threonine.....	7.2 mg/gm.
Tryptophane.....	2.6 mg/gm.
Valine.....	13.5 mg/gm.

Nutrition laboratory studies have demonstrated that V¹⁰ Protein Concentrate is a biologically complete protein. The efficiency of utilization of its protein is equal to that of the protein in meat and milk. †

V¹⁰ Protein Concentrate Contains:

27.19% protein	1.97% fiber
56.04% carbohydrate	3.02% ash
3.03% fat	8.75% moisture

CAL-ZO

*... still the
best all-purpose
dressing ointment*

CAL-ZO (Ulmer), originally prepared as the most suitable dressing ointment for pressure-sponge ambulatory treatment of varicose ulcers, continues as the ointment of choice for dressings of every nature. CAL-ZO is ideal whenever calamine and zinc oxide are indicated.

CAL-ZO provides a semi-fluid cushion at body temperature thus protecting lesions under treatment. Contact between gauze threads and surfaces. CAL-ZO, because of its special base, will not soak into dressing at body temperatures. Easy to apply. CAL-ZO is the choice of the clinician when all-purpose dressing ointments are considered. Available in 1 oz. or 1 1/4 lb. jars. . . . MM-657b

Any physician interested in serving as camp physician for a week or two this summer, is invited to investigate the opportunity at the Tomahawk Scout Reservation on Long Lake near Rice Lake, Wisconsin. The physician's family will be housed in a brand-new "doctor's cabin" complete with indoor plumbing, fireplace, kitchen-dinette, living room and two bedrooms, overlooking the lake. A boat and outboard motor are also at the disposal of the physician and his family.

Two nurses will be on duty at the health lodge to do the routine things related to cuts, bruises, fish hooks and poison ivy under the physician's direction. The "health lodge" is not a hospital but a place for treatment and an occasional Scout may be kept there overnight for observation, but, generally, sick boys go home at the doctor's recommendation.

Further information may be obtained from **Dr. Donald W. Koza**, 1210 Lowry Medical Arts Building, St. Paul 2, Minnesota.

* * *

The **State Medical Society of Wisconsin** is sponsoring a series of circuit teaching programs in postgraduate medical education beginning in July. To make them of the greatest value to practitioners in small communities, the subjects covered are generally in the fields of surgery, obstetrics, pediatrics and internal medicine. A registration fee of \$10.00 is charged for each clinic. This includes the dinner. The July circuit will be held July 16, 17 and 18 in Eau Claire, Ashland and Rhineland. The August circuit will be held August 20 in Delavan, August 21 in Wausau and August 22 in Manitowoc. The September circuit will be held September 10 in Lancaster, September 11 in Racine, and September 12 in Oconomowoc. Circuits will also be held in October, November and January. For further information, write the State Medical Society of Wisconsin, Madison, Wisconsin.

MINNESOTA BLUE CROSS-BLUE SHIELD

An outstanding service was rendered to the 830,000 Blue Shield subscribers, the physicians of Minnesota and Blue Shield by the Honorable E. J. Chilgren, Chairman, and members of the House Tax Committee when they unanimously approved the removal of the 2 per cent tax on money paid Blue Shield by its subscribers from the proposed tax bill on April 12.

Blue Shield was organized by the medical profession of Minnesota to help those with low and modest incomes to secure their medical care at a cost they can afford. Removing from the proposed tax bill the 2 per cent tax on Blue Shield's income from subscribers, as was done by the House Tax Committee, also has the effect of keeping the cost of medical care of those with low and modest incomes within the reach of their pocketbooks.

This action of the Tax Committee is evidence of the Committee's interest in the medical care of the people of the state and the Blue Shield voluntary, prepayment method of providing them medical-surgical-obstetrical care benefits at reasonable cost.

Over 1,108,000 Minnesotans are now enrolled through 420,278 Blue Cross contracts now in effect.

These totals represent a gain of approximately 71,000 participant subscribers and over 29,000 contracts compared to Blue Cross enrollment last year.

The frequency of hospital cases paid is continuing to increase. During the first three months of 1957, 49,737 cases were paid representing 479 cases per year per 1,000 contracts protected compared to 44,991 cases representing 466 cases per year per 1,000 contracts paid during the same period of the previous year.

As in most previous first quarter periods, respiratory illnesses represent the highest number of cases paid. Ranking second is pregnancies. This follows the same pattern as 1956.

However, during the first quarter of 1957, accident cases paid ranked third in number compared to fourth place during the same period of the preceding year of 1956.

More than one-half of the increased Blue Cross incident rate is attributable to the number of accident cases paid. If this trend continues throughout the year, the increase in number of accident cases paid annually would approximate 5,000, amounting to increases in hospital expense of an estimated \$400,000.

NOW U. S. SAVINGS BONDS PAY YOU HIGHER INTEREST—FASTER!

Every Series E United States Savings Bond you've bought since February 1, 1957 pays you a new, higher interest—3¼% when held to maturity! It reaches maturity faster—in only 8 years and 11 months. And redemption values are higher, too, especially in the earlier years.

About your older Bonds? Just hold onto them. As you know, the rate of interest a Savings Bond pays increases with each year you own it, until maturity. Therefore, the best idea is to *buy the new—and hold the old!*

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

MEDICAL LICENSURE EXAMINATIONS—RYPINS'. Eighth Edition. Walter L. Bierring, M.A.C.P., M.R.C.P., Edin. (Hon.). Former member National Board of Medical Examiners, American Board of Internal Medicine, Iowa State Board of Health; Professor Emeritus, Theory and Practice of Medicine, College of Medicine, State University of Iowa; Secretary, Federation of State Medical Boards of United States; Chairman (Hon.), 1933-1953, American Board of Preventive Medicine, Inc.; Director, Division of Gerontology, Heart and Chronic Disease, Iowa State Department of Health. 964 pages. Price \$10.00, cloth. Philadelphia: J. B. Lippincott Co., 1957.

PRACTICAL GYNECOLOGY. Second Edition. Walter J. Reich, M.D., F.A.C.S., F.I.C.S. Attending Gynecologist and Section Chief, Fantus Clinics of the Cook County Hospital; Attending Gynecologist, Cook County Hospital; Professor of Gynecology, Cook County Graduate School of Medicine; Assistant Professor of Obstetrics and Gynecology, Chicago Medical School; Attending Gynecologist and Obstetrician and Former Chairman of the Department, Grant Hospital; Consulting Gynecologist Oak Forest Infirmary, Oak Forest Tuberculosis Hospital, Hazelcrest General Hospital, Fox River Tuberculosis Sanatorium, Geneva Community Hospital And Mitchell J. Nechtow, M.D., F.A.C.S., F.I.C.S. Associate Attending Gynecologist, Cook County Hospital and Fantus Gynecologic Clinic; Associate Professor of Gynecology and Obstetrics, Chicago Medical School; Associate Professor of Gynecology, Cook County Graduate School of Medicine; Attending Gynecologist, Northwest Hospital; Chief of Gynecology and Obstetrics, Norwegian-American Hospital. 648 pages. Illus. Price \$12.50, cloth. Philadelphia: J. B. Lippincott Co., 1957.

THE HAPPY LIFE OF A DOCTOR. Roger I. Lee, M.D. 278 pages. Price \$4.00. Boston: Little, Brown & Company, 1956.

This book can be classed as an autobiography as well as a very good history of medicine of the first half of this century. Dr. Lee's accounting of his personal experience with the new advances and his reactions make it a most interesting type of history to read. To one who has practiced medicine through most of this period, and especially one who served as a medical officer in Europe during the first World War, it has a real meaning and brings to mind many personal experiences and trials.

A younger practitioner cannot but be impressed with the wonderful progress medicine has made, and perhaps be made to appreciate the means at hand to combat disease that were not available a few short years ago.

Dr. Lee was most fortunate in knowing and having known many of the "great in Medicine" of his period and conveys to his readers the personalities of these persons in a very interesting manner.

Protection against loss of income from accident & sickness as well as hospital expense benefits for you and all your eligible dependents.

It is very interesting reading for a Doctor of Medicine, and I believe most lay people would enjoy it.

F.H.M.

ION EXCHANGE AND ADSORPTION AGENTS IN MEDICINE. The Concept of Intestinal Bionomics. Gustav J. Martin, Sc.D. 333 pages. Price \$7.50. Boston: Little Brown and Company, 1955.

This book contains an adequate discussion of the physical and chemical principles involved in ion exchange. The author discusses the clinical application of ion exchange and adsorbing agents.

In the discussion of the chelating agents, those substances that make use of secondary valence forces in order to form loosely bound compounds that may become less permeable to various membranes, the author contributes to the organization of this subject. The review of the literature and remarks concerning the resins and other adsorbing agents, along with the chapter on intestinal bionomics, make the book part of the accumulating body of knowledge on the subject of ion exchange.

The nature of the discussions make the book of stimulating rather than of reference value to the research worker in basic science. The clinical investigator, internist and pediatrician will find a good deal of informative material.

• HERBERT W. JONES, JR., M.D.

FOR SALE—Used General Electric, 100 milliamperes x-ray machine, good as new. Model K-2-39, Serial Number 288395. Completely dismantled. Ready for shipment anywhere. Interested buyer can be assured of good deal. Write or call Grand Rapids Clinic, 504 First Avenue N.W., Grand Rapids, Minnesota, Telephone FAirview 6-3436.

FOR SALE—General Practice (not equipment) in town of 1,200; rich southwestern Minnesota County; medically unopposed; grosses over \$30,000.00 yearly. Nearest hospital 15 miles; closest doctor 12 miles; practice established 9 years. Purchase of modern rambler home required; possible financing in local bank. Will continue practice pending sale. Community might build clinic for new doctor. Address E-592, care MINNESOTA MEDICINE.

MEDICAL OFFICES AVAILABLE—Completely furnished, air-conditioned, roomy, in friendly farming community. Excellent hospital facilities. Owner at present serving as medical missionary; upon return will be interested in partnership. Excellent opportunity for young doctor to get a start and develop his own practice. Address E-585, care MINNESOTA MEDICINE.

Communication

Dear Editor:

On December 22, the *Journal of the AMA* published two appeals which were written by me, on and for the behalf of the refugee Hungarian physicians, in Austria.

When I wrote these letters on November 26 and 30, 218 refugee doctors had registered with us. As of today's date, there are 680.

Several U. S. physicians have written to me, inquiring as to the success of these appeals. I have informed them that the results were rather disappointing.

I received a letter from an American colleague, who writes:

"I am very much impressed with the work that you are doing for our colleagues, and I wish I could help you more. I thought maybe two suggestions could be helpful in receiving more contributions from the doctors here in the U.S.A.

First I think that if it would be possible to send a short mimeographed letter to the secretaries of all County Medical Societies with a request that they should read the letter to the members of the Society at their next meeting and asking a contribution of only \$1.00, nobody would refuse, and many would give much more. This certainly would bring in a large amount of money and maybe the distribution of these letters could be done by each State Medical Society so that your office would have to send these letters to forty-eight societies only, and the rest could be done by the State Societies. I feel that this approach would be more successful than the approach through the journal for the reason that few read your letter in the journal. As a matter of fact, in my community there are thirty doctors and nobody saw this letter.

"My second suggestion would be to get in touch with the Commissioners of Mental Health in each of the states and ask them about the possibilities of employing Hungarian refugee doctors in mental hospitals. The need is great and to my knowledge they were very satisfied with services they received from Hungarian refugee doctors up until now. I, myself, was working for seven months in a mental hospital."

(Name on request)

We would be most grateful to you, if you could publish my appeals in your JOURNAL, and call the attention of your local and regional Medical Societies to the fact

that over 680 Hungarian refugee doctors have, and most of them are still, receiving our aid.

Although the immediate urgency of the situation has been alleviated, there are presently over 450 Hungarian doctors in Austria who wish to return to their practice as soon as a change in the Hungarian political situation permits. In fact, we are urging these colleagues to remain here attending this possibility, for we feel that most of them, should they emigrate to the U.S.A., will encounter considerable difficulty with language and "State Board" requirements. To maintain them here will require our further support for several months to come.

We have found by experience that the best and most direct way to help our Hungarian colleagues is to accord them \$20.00 upon arrival, \$10.00 for every week they remain in Austria, and \$3.00 per day for board and lodging for those colleagues who have been designated to private quarters. We allot \$1.00 per day for each additional member of the doctor's family. There are no organizational or administrative expenses deducted. Every penny received is utilized for direct aid for our refugee Hungarian colleagues.

I am profoundly grateful for your kind humanitarian gesture, which I assure you, will find full recognition in the practical assistance it provides for its needy beneficiaries.

Your cooperation in this matter would be gratefully appreciated.

Electrolyte and Fluid Balance in Infant Diarrhea

JAMES L. DENNIS, M.D.
Oakland, California

PERHAPS nowhere else in medicine are the diverse perspectives of the rural practitioner and the academician so well demonstrated as in the approach to the management of diarrhea in infants. To be useful, advances in medical knowledge must be made available to the physician in the field in a form that is both practical and safe. Unfortunately, advances in fluid and electrolyte balance have been reported in specialty journals supported by a mass of details based on the laboratory, the laboratory which sometimes is not available to the general practitioner. This paper will attempt to perform a marriage between the academic and the practical.

To develop understanding, we must review the attitudes that exist. The academician pursues the philosophy that diarrhea is not a disease but rather a symptom with many, many causes; that regardless of the cause, the disturbed or altered physiology and the ultimate death that ensues come as a direct result of the loss of vital body fluids and electrolytes. Hence, it follows that the *primary objective* in the treatment of diarrhea must be the prevention of and the correction of fluid and electrolyte loss. This concept has been augmented by the experience of the medical center specialist who deals almost exclusively with the infant who has a severe diarrhea and who is therefore hospitalized to care for his extreme dehydration and depletion.

In contrast to this, the physician in practice will see many babies with mild diarrhea. He is likely to feel very comfortable in prescribing one of the proprietary antidiarrheal drugs. The academician does not get very enthusiastic about the use of drugs, preferring to rely almost entirely upon precisely calculated fluids and electrolytes.

Why is this? The academician will say that the old theory of intestinal intoxication as advocated by Metchnikoff has not been demonstrated to have clinical significance, and he will quote Best and Taylor to that effect. They observe that most of the proprietary antidiarrheal drugs have been promoted as being intestinal, adsorbing and detoxifying agents.

Insofar as fluids and electrolytes are concerned, the country doctor, his grandfather before him and probably his grandmother, has always prescribed small, frequent amounts of electrolyte fluid in the nature of rice and barley water, skimmed milk, sweetened tea, apple juice and what have you. These are all potent sources of sodium, potassium, chloride and other minerals as well as water. Does the realization of *why* these things are effective make them obsolete? Must we give our young mothers an expensive prescription for an ounce or two of what is essentially salt, sugar and soda? I think not. This leads back to the question of what place, if any, do the antidiarrheal drugs have in the treatment of diarrhea?

Some years ago at the University of Texas, I participated in a study set up and designed to determine whether we could find an answer to this question. The first step was a review of the literature. Papers advocating the use of the proprietary drugs revealed that the children had also received vigorous supporting fluid and electrolyte therapy. On the other hand, in the literature recommending the use of fluids and electrolytes exclusively, there was no instance where any proprietary drug had been given. This posed a nice question.

Realizing that there is a great difference in the clinical problem between mild diarrheas treated in the out-patient clinic and the severe diarrhea treated in the hospital, the study was organized so that in every instance, whether in the outpatient

Presented before the Minnesota Academy of General Practice, Saint Paul, Minnesota, October 17, 1956.
Dr. Dennis is Medical Director, Children's Hospital of the East Bay, Oakland.

clinic or in the hospital, the patient received calculated basic fluid and electrolyte requirements. Then in addition, according to a random-choice method, some patients were selected to receive one of the antidiarrheal drugs. One such drug was a multiple or polyamine exchange resin which has since been marketed under the name of Resion.† Omitting the details of the study, we found that the infants with severe diarrhea, with severe dehydration and electrolyte depletion, were not benefited at all by the proprietary drugs. This was not unreasonable when you realize that these babies were usually so sick that they could not tolerate anything by mouth.

On the other hand, we were quite surprised to find that the infants with the milder diarrheas who had been given the polyamine resin along with their basic fluid electrolytes had a shorter recovery period than those who had had only their calculated amounts of fluids and electrolytes by mouth. So it seems logical to conclude that both attitudes may be essentially correct when applied with good clinical judgment.

If a severe diarrhea patient is benefited *only* by appropriate fluids and electrolytes, it behooves doctors in practice, whether in a mountain hamlet or in a university center, to understand some of the basic physiologic principles involved in the management of fluid and electrolyte imbalances in the infant. I should like to review some of the academic concepts, to show why we behave the way we do.

To begin with, what is the difference in diarrhea in an infant and an adult? In general, the disease is the same; the difference is in the patient. To illustrate, take a hypothetical 10-pound baby. This baby contracted acute diarrhea yesterday and is brought into the office today. The "10-pound" baby weighs only 9 pounds today and is severely dehydrated because the loss totals one-tenth of the baby's body weight.

One pound of water is 453 grams, which is equivalent to 453 cc. So a baby who has lost approximately a little less than a pint of water has become severely dehydrated. Mr. Average Adult, weighing 150 pounds, would have to lose 15 pounds or nearly 7,000 cc. (or 7 liters) to experience the dehydration and shock which this baby manifested with the loss of only one pint of fluid.

The same delicate balance holds true when you

put the needle into the baby's vein. The baby who inadvertently gets 400 to 500 cc. too much in a twenty-four-hour period has had dumped into his blood supply the equivalent of 7 liters of excess fluid in the adult.

Most physicians have been taught to describe electrolytes in terms of milligrams percent. In recent years, electrolytes have been discussed in terms of milliequivalents per liter. In practice, do not be too troubled by not knowing the details of this change-over.

The milligram is a unit of weight and, as such, does not convey any idea or imply the amount of potential chemical activity. It is very much like having a pound of feathers or a pound of steel in a sack. They both weight one pound, but anyone would prefer to be hit over the head with the feathers. So we are talking about elements of different powers. Another analogy: we would not invite 1400 pounds of boys and 1400 pounds of girls to a teen-age dancing party. Rather we are interested in the combining power of two oppositely charged elements. They must be equal in numbers. This comes back to the old basic chemical law that in any given solution there must be an equal number of positively charged ions and negatively-charged ions. This is electrical balance or equivalent balance. Actually, there has been no change in the laboratory techniques. The milligram percentage per 100 cc. is determined first and then transposed into milliequivalents by an equation. It is very impressive and necessary in the laboratory research center, but not always practical for the man in practice. Before presenting a simplified approach which can be used anywhere, I want to pursue the physiologic approach a little further.

An infant's weight is 75 per cent liquid: 50 per cent in the form of intracellular fluids, 20 per cent in the interstitial fluids between the cells, and 5 per cent in the intravenous fluid compartment. Only 25 per cent of the body is solid. This is a relatively higher percentage of water than in an adult. As for the chemical composition of these compartments, sodium is the principal cation in the extracellular compartment and chloride is the principal anion. In the intracellular compartment, there is an entirely different "population." Here sodium comprises only 10 milliequivalents of the cation electrolyte content, whereas potassium becomes predominant and preponderantly so. An-

TABLE III. MILD DIARRHEA—CLINICAL SIGNS

Slight increase in number and fluid content of stools.
Weight loss, less than 5 per cent of body weight.
No gross signs of dehydration.
Retaining oral fluids.
Good renal flow.
Skin turgor normal.
(Treatment: home, office or O.P.D., oral electrolyte fluids.
Adjuncts—antidiarrheal drugs).

ons are principally phosphorus and proteins with essentially no chloride.

This demonstrates that (1) the chemical composition of what we measure in the blood is not at all what we have in the cells; (2) in serum analysis we measure the vascular compartment content, the very smallest source of our fluid electrolyte situation at any given time. Furthermore, a baby who is severely dehydrated to the point of being in shock has a very greatly diminished circulating volume. If this blood is drawn to do the initial determinations, it may be so concentrated that the results have no meaning. The potassium level may be extremely high due to this concentration, while the cellular potassium may be quite depleted. Regardless of the value of laboratory findings, initial therapy must start before the reports come back and must be based entirely on clinical observation and judgment.

Normal electrical balance in the serum (Table I) has 155 milliequivalents positive charges and 155 milliequivalents negative. Theoretically, if we could measure the anions and the cations of all of these elements, we could replace any imbalance that exists with mathematical precision. Actually, this is not possible.

The intracellular compartment (Table II) is entirely different with 195 milliequivalents of anions and cations in a balanced solution but having no correlation to what is measured in the serum.

Now for a simple clinical approach: is the infant mildly, moderately, or severely dehydrated? Since this is basically a clinical problem, not a laboratory problem, let us approach it from the clinical side. The case is one of *mild diarrhea* (Table III) in a baby who has minimal signs, maybe a few loose stools and little or no fever. The skin turgor

TABLE IV. MODERATE DIARRHEA—CLINICAL SIGNS

Frequent fluid stools.
Weight loss more than 5 per cent but less than 10 per cent.
Moderate signs of dehydration.
Continued loss of fluid by vomiting and diarrhea, or questionable ability to retain fluids.
Urine output diminished-concentrated.
Skin, hot and dry.
(Treatment: optional—oral or per hypodermoclysis. If home conditions are poor, hospitalize.)

is still good; the baby takes oral fluids. There is no question that this baby can be treated in the office, at home, or in the outpatient department. Frequent sips of some electrolyte fluid are prescribed: one teaspoon of salt and four table-spoons of Karo syrup to one quart of boiling water, or the fluid left from boiling rice or barley with a little salt added.

As for the amount of fluid required, 60 cc. per pound is the minimum daily normal requirement. Prescribe at least this amount by telling the mother to give an ounce every hour, or two ounces every three hours, or three ounces every four hours. It is necessary to give her a definite goal. It does little good to tell the mother to give the baby "all the fluids you can."

Concerning antibiotics in diarrhea, the study previously mentioned showed that the use of polymyxin or neomycin contributed very little to the shortness of the course; although if we watched the stool cultures, they were very dramatically reversed. Judgment is necessary here, too.

Adjuncts such as Resion and the so-called intestinal-adsorbing agents cannot replace electrolytes, but in some manner they appear to reduce the loss of fluids and electrolytes in the mild cases.

The child with *moderate diarrhea* (Table IV) may have a hot, dry skin, moderate fever, a questionable oral intake of fluids, and diminishing urine output. This baby may be vomiting a little. It may begin to look a little toxic. The first question is, "Where do I treat this baby?" If the baby is vomiting or has a poor home situation, it belongs in the hospital because it will be severely dehydrated by tomorrow. If this baby is from a good home and it seems to be able to retain some fluids, send it home and keep in close contact with the

Loss of skin turgor.	
Anuria.	
(Treatment: hospitalization and intravenous. Fluids mandatory).	

mother. See the baby the first thing in the morning and make use of the "laboratory test"; that is the most valuable of all. *Put the baby on the scale.* A baby who is retaining fluids will have maintained its weight, or gained an ounce or two. The baby who has continued to lose more fluids than it has taken in will have lost an ounce, or two or three; and that may be the only indication for putting the baby in the hospital. That fine, old scale, weighing the baby in pounds, is more valuable than all the electrolyte determinations that can be done at this stage of the game.

Remember the fluid requirement: 60 cc. per pound for mild diarrhea; increased to 80 cc. for moderate dehydration. This may be given to the baby orally if the child is taking oral fluids, or it may be given as a clysis, using the isotonic combination of 2.5 per cent dextrose in water in half normal saline. I would like to point out again that parenteral infections must be treated; the adjuncts may be used—they are optional.

Now we come to the baby we are going to worry about; namely the child with *severe diarrhea* (Table V). This baby may have an extremely high fever, 106° or 107°, or it may have proceeded so far as to be in a state of shock with a subnormal temperature. There is a loss of skin turgor; skin resembling a rumpled towel; sunken eyeballs; central nervous signs; perhaps most significant of all, anuria. For this infant, the hospital and intravenous fluids are *mandatory*. This baby must never be given a clysis. This baby is in peripheral circulatory collapse, hence, will not pick up the fluids or the electrolytes from a clysis. From the standpoint of total fluid requirements, one can very simply remember for severe diarrhea to give 100 cc. per pound per day.

Objectives of therapy must be kept in mind (Table VI). If the baby is in shock, obviously the first thing to do is to treat shock. The next objective is to restore kidney function. These two things are "musts." For shock, inject 10 to 15 cc. per pound of electrolyte fluid or a plasma expander. Why do I say plasma expander? Plasma of

TABLE VI. SEVERE DIARRHEA—PRINCIPLES OF TREATMENT

1. <i>Shock</i> , (restore circulating fluid volume), push i.v. of ½ N.S. in 5% D/W or plasma expander. Give 15 cc. per pound at rate of 5 to 10 cc. per minute.
2. <i>Renal function</i> , (restore renal flow), saline-glucose mixture at 20 drops per minute until urine output established.
3. Restore <i>fluid and electrolyte</i> balance (See text).
4. Periodic re-evaluation of clinical status.
5. Establish oral intake (fluids-electrolytes-calories).

the pooled blood type is fraught with the danger of homologous serum jaundice and I hate to use it; although I must admit that in an emergency with a baby in shock and plasma available, I probably would use it. Follow with a solution of one part saline and two parts 5 per cent glucose water. Why not use normal saline? Remember the milliequivalent values in serum. There are 145 milliequivalents of sodium, and only 103 of chloride, other anions making up the difference on the acid side. With sodium chloride in so-called normal saline, there are 155 milliequivalents of sodium and 155 milliequivalents of chloride. In severe infant diarrhea, the infant usually loses more sodium and relatively less chloride. So to give a solution with equal parts of sodium and chloride adds excess chloride to the serum in a situation in which chloride may be already high.

Another reason for combining the saline solution with the dextrose and water is that in normal saline there is no "free" water, since it is isotonic with normal serum. The extra chloride present must be excreted, hence, would require even more water, which is not available. By giving dextrose and water, we are giving dextrose which will be converted to glycogen, and freeing the water for kidney function.

What about the commercial solutions? Almost every hospital has a pet: Darrow's solution, Hartmann's solution, Butler's solution and so on down the line. None of them is specific and all of them will work in the hands of men who know what they are doing with them. I prefer to teach my residents to think basically in terms of saline solution and glucose and water.

For the first hour, or until the urine output is established, drip this relatively rapidly at 20 drops a minute. When the kidneys are functioning well, add potassium. It requires approximately 2 milliequivalents of potassium per pound per day. (A solution of potassium chloride, in which there are two milliequivalents per cubic centimeter, is available in ampules.†) Some practitioners may prefer

†Abbott Laboratories.

one of the commercially prepared polyionic solutions, using it in place of the saline. However, one part of any balanced electrolyte solution to two parts of glucose and water makes a good safe hypotonic solution.

The problem of the rate of flow to drip the fluid in order to deliver the twenty-four-hour requirement can lead to a good deal of calculating. Actually, one need only take the factor (100) and divide into the total number of cubic centimeters required per day. For a 12-pound baby, needing 1200 cc. per day, the answer is 12 drops per minute (one drop per pound per minute). To be safe, I usually write the order "10 to 12 drops a minute," so it will not go in too rapidly.

Finally, we come to the method of getting the fluid into the baby's veins (Fig. 1). For a number of years, we have advocated scalp vein technique using a .023 gauge polyethylene tubing. This tubing comes already made up. If not, one can easily be made. Take a 23-gauge hypodermic needle, break it off, and put it in the distal tubing. Put a short, blunt, beveled 23-gauge needle in the proximal end and connect to a syringe. Fill it with saline, grasping the needle at right angles with a hemostat. As the needle gets under the skin, an assistant pulls back on the plunger. Once the vein is entered, the blood comes back, and the tubing connected with a Murphy drip. This simple procedure is good only in the small infant. (Remember, once the vein is entered, the greatest danger becomes one of excess fluid.

Admittedly, there are times when it is necessary to cut down on a vein. The most useful site is the superficial saphenous vein at the medial aspect of the ankle. I do not like to cut down, if I can avoid it, for several reasons. First, by putting in either a large-caliber needle or a large-caliber polyethylene tubing with an opening that is patent, one is likely to drown the baby. If the fluid runs too rapidly, it does not take much time to lose the child. Second, infection and phlebitis are quite

common following this procedure. Third, no matter how good the surgeon, a permanent scar is the result.

In conclusion, I would like to recapitulate the

Fig. 1. Needle inserted into scalp vein. Assistant pulls on plunger so that blood enters polyethylene tube when vein entered.

foregoing clinical procedure which is based upon academic concepts, and which can be used by any practitioner anywhere.

1. Classify the dehydration as mild, moderate or severe.
2. Give 60, 80 or 100 cc. of fluid per pound per day, orally, by clysis, or intravenous drip according to severity.
3. Treat shock and establish renal function.
4. Drip in the total fluid requirements.
5. Figure the rate of flow by dividing the total number of cubic centimeters per day by the factor of 100.
6. Once the baby is out of shock, there is no emergency and overhydration constitutes the greatest danger.
7. If the diarrhea is a rare type (e.g. adrenal insufficiency), then the laboratory becomes invaluable as a guide to therapy.

ARTHRITIS FILM RELEASED

A 16 mm. color motion picture on the uses of steroids in the treatment of rheumatoid arthritis has been released for showing to professional groups by the research division of Schering Corporation.

The film reviews the chemistry, physiology and clinical application of the new "Meti" steroid hormones in rheumatoid arthritis and other collagen diseases. It presents the most commonly accepted theories of adrenal corticosteroid therapy and reflects the current knowledge of the subject.

The 25-minute film, which is the fourth in a series

on hormone therapy and the endocrines, was produced by the company's Clinical Research Division and Biochemical Research Department. Three leading rheumatologists and endocrinologists cooperated: Dr. Joseph Eidselsberg, New York; Dr. Abraham Kolodin, Montclair, N. J., and Dr. Evelyn Merrick, Orange, N. J.

The film is available to medical and allied professional groups on loan without charge. "Meti" Steroids in Rheumatoid Arthritis" and other films may be obtained by writing to The Audio-Visual Department, Schering Corporation, Bloomfield, N. J.

The Beck Operation for Coronary Artery Disease

CLAUDE S. BECK, M.D.,
BERNARD L. BROFMAN, M.D.
Cleveland, Ohio

IT IS the general practitioner who sees the patient stricken with a heart attack, and it is he who carries the patient through his illness. As you know, coronary artery disease or angina pectoris is a common disease which kills or incapacitates a large number of people. In many respects it is a more important disease than cancer, because it kills and incapacitates many more people than do all forms of cancer combined. It is so common that some medical cardiologists make light of the disease, but the death toll speaks for itself. The cardiologist often seems to be satisfied with the treatment that he administers to the patient. Both of these reactions produce a feeling of complacency toward this disease and also toward the patient who has it. Instead of being satisfied with treatment of coronary artery disease, we should be critical of and dissatisfied with present day treatment because it leaves so much to be desired.

Limitations of Treatment

No form of treatment cures the disease. No treatment reduces the occlusive process in the arteries; no treatment prevents further development of arterial disease; no treatment restores degenerated myocardium. The electrocardiogram is not treatment of the disease. No medical therapy can change or improve the anatomy of the coronary arteries. Perhaps in the future atherosclerosis of arteries may be prevented, but this cannot be done at present, and the possibility of this accomplishment in the future is remote and should not reduce our dissatisfaction with medical therapy.

Axiom in Coronary Artery Disease

When a coronary artery is narrowed or occluded, the fate of the patient depends upon the amount of blood distal to the stenosis or occlusion. This is a self-evident truth, fundamental in

understanding the disease and essential for effective treatment. It is an understatement to say that this working-principle has been neglected. The electrocardiogram has been of such absorbing interest to the medical cardiologist that the fundamental problem in treatment has been disregarded.

What Happens?

What happens when a coronary artery is narrowed or occluded? Two things may occur: One is the production of electrical currents; the other is the death of muscle. Currents are produced when poorly oxygenated muscle is in contact with well oxygenated muscle. These differences in oxygen content are produced by disease in an artery. We call them oxygen-differentials. Emphasis is placed upon differences in oxygenation; emphasis is not placed upon amount of oxygenated blood delivered to the heart, because a uniformly cyanosed heart does not have these currents. These differentials produce currents which may become strong enough to fibrillate the heart. This is the fatal heart attack. The other thing that may occur after a coronary artery is narrowed or occluded is infarction or death of muscle, due to the inadequate amount of blood reaching the muscle. It is not related to differentials in oxygenation. These are two separate biologic processes, one due to differences in oxygenation, and the other to inadequate blood supply.

There are two modes of death from coronary artery disease. One is due to the fibrillating currents that kill so many people; the other is due to muscle death which ultimately kills the victims by heart failure. The currents are not strong enough to fibrillate the heart and the heart keeps on beating; thus the heart goes from one infarct to another until ultimate failure occurs. These two types of death are different—as though they were produced by two different diseases. Sometimes the heart which seems to be anatomically capable of continued function stops in standstill and does not fibrillate, because the muscle fails to respond to the normal electrical impulse.

Presented to the Minnesota Academy of General Practice, St. Paul, October 17, 1956. From the Western Reserve University, The University Hospitals and Mount Sinai Hospital, Cleveland, Ohio.

We are in an area of "muddy thinking" concerning coronary artery disease. A recent experience will illustrate this. I was a member of a panel and the subject for discussion was "the treatment of myocardial infarction." However, this title was not correct for the discussion that took place. The intent in using the words "myocardial infarction" in the title was not to confine discussion to infarction when something else killed the vast majority of coronary victims. This title and the discussion called forth by this title indicate a conflict in the science. In this panel discussion an attempt was made to define "a mild coronary occlusion." Some of the patients discussed had a mild coronary occlusion and did not live. It was a mild occlusion yet the patient died. This again indicates conflict in the science. An informed society expects something better than this from the medical scientist.

Trigger

Poorly oxygenated muscle in contact with well oxygenated muscle is a condition that gives rise to electric currents. These currents may be strong enough to fibrillate the heart and produce the fatal heart attack. We refer to this condition as "pink and blue" in the heart. It accounts for tens of thousands of deaths yearly in this country, on the golf course, shoveling snow, watching television, or during sleep. In many of these victims, the heart anatomically is capable of continued function for years were it not for the current that destroyed the normal impulse. The death factor is often a small factor; it need not be an overwhelming destruction of the heart. The death factor may be preventable and it may be reversible. The term "trigger" is applied to a localized area of ischemia. It is readily produced experimentally by placing a ligature on coronary arteries. After an ischemic area of muscle has been produced, any addition or subtraction of blood in reference to the trigger makes a difference in what occurs. If a little additional blood is made available to the trigger, then its destructive power is reduced; if the ischemia is made more severe by further reduction in blood supply, then it becomes more destructive.

The Trigger's Blood

If the trigger is a small area of muscle, a few drops per minute or one or two cubic centimeters per minute help a great deal. This was shown

in our experimental laboratory. When the descending ramus of the left coronary artery is ligated at its origin in the dog, 300 c.c. per hour or 5 c.c. per minute made available to the muscle formerly supplied by this artery will prevent fibrillating currents. For the circumflex artery, 390 c.c. or 6.5 c.c. per minute will prevent fibrillation. These amounts of blood will not prevent infarction but they will prevent fibrillating currents. For smaller areas of muscle, smaller amounts of blood are protective.

Segmental Anatomy of the Coronary Arteries

Each coronary artery and each branch of a major coronary artery supplies a discrete segment of muscle. The discrete nature of this anatomy makes the heart vulnerable to small alterations in blood supply, but there is some variation in this anatomy. About 9 per cent of humans have some connections between arteries or between branches of arteries. These people were probably born with these intercoronary communications; they are the people who are more likely to survive coronary occlusion because their hearts are protected. Figure 1, A and B, shows two normal dog hearts. The segmental nature of the arteries is shown; the communications between arteries are few. Intercoronary communications can be produced by surgical operation. These communications are illustrated in C and D of Figure 1, compare with A and B. These hearts are protected by these new channels produced by operation.

The Beck Operation

The operation is a simple one and consists of four steps. The first is the passage of a ligature around the coronary sinus about 1 or 2 cm. from its ostium in the auricle, constricting the sinus down to a lumen of about 3 mm. This narrowing of the sinus accomplishes certain favorable and unfavorable results. It brings about somewhat greater extraction of oxygen from the venous blood, which normally is already greatly reduced. The mild venous stasis reduces oxygen differentials in the presence of arterial occlusion, and this probably protects the heart with coronary disease. It also produces intercoronary channels. On the other hand, increased capillary pressure may reduce total coronary artery inflow. Our opinion is that this step in the operation makes it more effective. If the sinus is hard to ap-

proach at operation, as in cases with cardiac enlargement, this step is omitted. However, only rarely is this the case. We have seen no ill effects from it at operation.

The second step consists of abrasion of the lining of the parietal pericardium and the epicardial surface of the heart. This produces inflammation, with resultant intercoronary channels. Necrotizing chemicals such as carbolic acid should not be used for this purpose.

The third step consists of the application of about 0.3 gm. of coarsely ground asbestos to the surface of the heart, producing a mild inflammatory reaction. Asbestos is the most effective and least irritating substance that we have tested.

The fourth step is to bring the mediastinal fat into contact with the heart so that it can act as a graft upon the heart. Each step in this operation contributes something to the final result. The operation itself is tolerated remarkably well. It requires approximately one hour to perform, but it should be emphasized that there is no need for haste during the operation. In no instance has the duration of operation contributed to any untoward complications.

Effectiveness of This Operation

Figure 1 shows the effectiveness of this operation. Operation produces intercoronary arterial communications so that a blood cell, once it enters the coronary system, can go where it is needed most by the heart. One of the tests that we use to measure the effectiveness of these intercoronary channels was the Mautz-Gregg backflow test. This test is done by ligating the circumflex artery. It is then cut distal to the ligature and the open end of the artery is cannulated. The amount of blood that comes out of this artery is the amount available to the muscle beyond the ligature. The average backflow in seventy normal dogs is 3.8 c.c. per minute or 228 c.c. per hour. Average backflow in forty-one operated dogs is 8.5 c.c. per minute or 510 c.c. per hour. Operation adds an average of 282 c.c. per hour to the circumflex area beyond the occlusion. It is comparable to a transfusion of 282 c.c. of blood added to the quantity already present. This blood is available to meet the crisis of the occlusion. There is no evidence, no scientific measurement, to show that any of the available medical measures add (or subtract) a single drop of blood to ischemic muscle. In dogs

undergoing one-step ligation of the descending ramus of the left coronary artery at its origin, the 70 per cent mortality in normal dogs was reduced to 26.6 per cent by operation. This decrease of 43.4 per cent is due to reduction of oxygen differentials by intercoronary channels. The process of infarction was reduced 60 to 70 per cent in size by this operation. These results have been well tested in the laboratory.

Selection of Patients for Operation

1. *Prophylactic Group.*—Up to the present time operation has not been done as a prophylactic measure, but inclusion of this group is under consideration. It is illustrated by a man, aged forty years, who lost his father, an uncle and two brothers at the age of forty-one to forty-five years. This man had no symptoms of the disease. The question he put to us was whether he should be protected by the operation now, when the risk of operation was slight and before occlusion developed. Operation was advised.

2. *Coronary Insufficiency. Angina Pectoris.*—Operation is advised when the diagnosis is made. The risk is small.

3. *After One or More Infarcts.* The interval between operation and the last infarct should be at least six months. This gives time for repair and for the disease to stabilize so that the condition after operation can be compared to the condition before operation.

Contraindications

1. *Signs of Congestive Heart Failure.* These include dyspnea at rest, rales in the lungs, and peripheral edema.

2. *Marked Enlargement of the Heart.* This indicates extensive myocardial damage, a condition that can scarcely be helped by operation and the risk is definite.

3. *Progression of Symptoms.* Operation is delayed until the clinical course becomes stabilized. If the stenosing disease is rapidly progressive, operation may transform an impending medical mortality into an evident surgical mortality.

Clinical Results

Of 100 patients who were followed six months to five years after operation and who could be evaluated, there was no pain in forty, less pain in forty-eight, and a total of 88 per cent improved.

Fig. 1. The coronary arteries were injected. A and B are normal dog hearts. Note the segmental distribution of the coronary arteries and their branches. Communications between arteries are sparse. C and D are dog hearts after operation. Note the intercoronary channels. These are protected hearts. E and F show a human heart. This patient had been incapacitated, but he worked for nine months without pain after operation. His pain returned and he died in three months. Note the intercoronaries. Three adjacent vessels are occluded in F on the left side of the photograph. Probably this area produced pain and fibrillating current because it is poorly vascularized. This is classified as a good or excellent result from operation. Operation does not pretend to cure coronary artery disease.

There were thirty-four better able to work without limitation, and fifty-six better able to work with moderate limitations, or 90 per cent better able to work. Frequently, the patient states that the tightness in the chest is relieved as early as the first week after operation. This improvement is accepted by us because it can be demonstrated that improvement in circulation can be achieved in a few days. In the majority of patients the degree of improvement is such that only by direct contact with the patient can this be appreciated.

Mortality

In the last 171 consecutive patients operated upon, there was one death during operation, a case in which the heart fibrillated. Another heart fibrillated several hours after operation. The chest was opened; the heart was pumped by hand; the patient was conscious without a heart beat for about ten hours, after which pumping the heart was discontinued. The arterial disease in each heart was severe and extensive, and the inflow was inadequate to support the heart beat. Another death occurred from another arterial occlusion before the patient was discharged from the hospital.

In this series there were 100 consecutive operations with zero operative mortality. In this series the common left coronary artery was soft, pulsated, and felt to be approximately normal in 76 per cent of the cases. If this artery is soft and normal, the assumption is made that the inflow of blood is adequate and the problem in physiology and therapy is that of redistribution in the peripheral areas of myocardium, and operation can accomplish a balanced distribution. This record in surgical therapy speaks for itself.

Conclusion

1. The most effective treatment of angina pectoris is accomplished by surgical operation.

2. Operation redistributes the available blood in the vascular tree so that it can accomplish its greatest amount of good.

3. In the experimental laboratory, operation saves life after a coronary artery is ligated. It also saves muscle destruction. These facts were established by controlled experimentation. No doubt the same protection is given to the human heart.

4. The operative mortality in 100 consecutive patients was zero.

FAR EAST FLU VIRUS VACCINATION POLICY ISSUED

The Department of Defense has issued policy guidance for military to be vaccinated as soon as possible with a special single-strain vaccine to combat a previously unidentified virus which has caused an outbreak of influenza in the Far East.

Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical), in a Department of Defense Instruction, said that the vaccine also will be made available to civilian employees and military dependents on a voluntary basis at overseas stations.

The Department said it was supporting the use of the new vaccine in view of the threat to the national security through the loss of manpower and personnel which could occur as a result of an epidemic involving the Armed Forces. Within the Armed Forces, as of this date, no deaths resulting from the new virus have been reported.

An influenza outbreak in Hong Kong, reported in the press on April 18, first alerted Army Medical Service personnel to the new danger. The same day, Walter Reed Army Institute of Research, and Major General Silas D. Hays, Army Surgeon General, took action. A cable was dispatched to the Chief Surgeon of Army Forces in the Far East, Brigadier General

Joseph H. McNinch, suggesting that an epidemiologist be sent to Hong Kong to investigate, and a medical officer was sent at once.

Twenty-five days after the first report of the disease, the virus was in the Institute, and nine days later the laboratory had identified the virus as one different from any known influenza strain. The Armed Forces Epidemiological Board have been actively concerned with the problem.

Anticipating a continuing threat from the new Far East influenza virus, Dr. Maurice R. Hilleman, Chief of the Department of Respiratory Diseases at the Institute of Research, requested on May 29, through the Surgeon General's Office, an emergency purchase of diagnostic laboratory materials. Without these materials, laboratory diagnosis of the new strain is impossible. Because the new Far East strain was so different from the older viruses, no materials existed which would permit its diagnosis.

With this emergency purchase made, the difficulty was overcome. These materials will now be distributed to service laboratories as required.

The Departments of the Navy and Air Force also have initiated studies on the infectivity of this disease.

Medical Aspects of the Surgical Treatment of Coronary Heart Disease

BERNARD L. BROFMAN, M.D.
Cleveland, Ohio

THERE can be little doubt that the ultimate solution to the problem of coronary heart disease lies in prevention of the occlusive degenerative process in the coronary arteries. However, until this becomes a practical reality, the patient who is a victim of the clinical manifestations of coronary heart disease should be given the benefit of such procedures which effectively and safely produce clinical improvement and reduce the exorbitant mortality associated with this disease.

In a fundamental sense, angina pectoris, myocardial infarction, and the fatal heart attack merely represent varying responses of the heart to the occlusive process in the coronary arteries. However, there is no obligate relationship between the degree of reduction in coronary inflow and the consequences thereof.¹ The essential role of inter-coronary arterial channels in preventing the catastrophic consequences of coronary artery disease is evidence of the protection afforded by a more equal distribution of the available coronary inflow.² If this collateral circulation is adequate, complete coronary artery occlusion may occur without significant muscle damage. The fate of the myocardium and indeed the fate of the patient depends upon the amount of blood available beyond the stenosis or occlusion of the coronary artery. The natural development of inter-coronary communications is an uncertain process and is unfortunately most frequently inadequate.

The Beck I operation has evolved as a safe and effective procedure to be applied to patients with coronary artery disease. The achievement of a low operative mortality and the demonstration of clinical benefit justify application of the operation to a large group of selected patients with clinical evidence of coronary artery disease. The surgical details have been reported elsewhere.³ Briefly, the

operation consists of: abrasion of the parietal pericardium and epicardium, partial ligation of the coronary sinus, instillation of asbestos, and grafting of parietal pericardium and mediastinal fat to the heart. This is done as a one-stage procedure. This report is based upon a series of 225 consecutive patients operated upon for coronary heart disease, in Cleveland, during the six-year period from January, 1951, to January, 1957. The medical evaluation and selection of patients was carried out by the medical cardiologist; the operation was performed by Dr. Claude Beck.

Indication for Operation

Operation is indicated in patients who have clinical evidence that coronary arterial disease has compromised the myocardial blood supply. The achievement of a low operative mortality now justifies the application of the operation to patients with very "early" disease, before extensive myocardial damage has occurred. By the same token, the protection afforded by operation need not be withheld until the patient has had at least one myocardial infarction; early operation can reduce the 10-20 per cent mortality associated with the first episode of myocardial infarction. Operation may also be performed even after several episodes of infarction; but, obviously, little benefit can be achieved if the heart is damaged to the point of dilatation.

In the classification of patients with clinical evidence of coronary artery disease, consideration must be given not only to the degree of myocardial degeneration, but also to the progression of the occlusive process in the arteries. The following preoperative classification has been found useful:

Group 1. Patients with mild symptoms. Usually under fifty years of age. May have small infarct and/or mild angina.

Group 2. Moderately advanced disease. Moderate to severe angina. May have one or more infarcts. Normal heart size.

Presented at the sixth annual fall refresher meeting of the Minnesota Academy of General Practice, Saint Paul, October 17, 1956.

Dr. Brofman is Director of Cardiovascular Research, Mount Sinai Hospital of Cleveland, Ohio.

- Group 3. (a) Salvage cases. Extensive muscle damage. May have large heart and congestive heart failure;
 (b) Status anginosus; or
 (c) Certain contraindications.

Contraindications to Operation

Acute myocardial infarction, or even suspicion of impending infarction, precludes operation for at least four to six months. In addition to the obvious dangers of operation during the acute stage, the delay allows for development of natural compensatory mechanisms. Operation is particularly hazardous in younger patients with rapidly progressive symptoms, particularly in those without previous myocardial infarction. These patients are prone to the development of areas of ischemia during or immediately after operation. These hearts tend to develop electrical instability⁴ with resultant ventricular fibrillation, so that an impending medical death may become a surgical mortality.

Cardiac enlargement and evidence of congestive heart failure constitute a relative contraindication to operation. However, in 20 per cent of the patients operated in this series, the left ventricle was fluoroscopically enlarged. At least one-fourth of these patients had objective evidence of early congestive failure. Although it is too late for much benefit in such patients, the heart is remarkably stable and they tolerate operation quite well.

Although a moderate degree of blood pressure elevation was present in 25 per cent of the patients operated, severe hypertension, or any other associated disease, which, *per se* significantly limits life expectancy, contraindicates operation.

Symptoms and Duration

In the present series, 75 per cent had suffered at least one clinically proved myocardial infarction. Two or more infarctions had occurred in 20 per cent. Angina pectoris, ranging in severity from very mild to complete status angiosus, was present in 95 per cent of the patients operated.

The duration of symptoms, *per se*, of course gives no indication of the severity of the disease. The range in this series was four months to thirteen years, with an average of 2.9 years. In general, patients with symptoms of longer duration appeared to tolerate operation better.

Preoperative Management

The purpose of the preoperative study is to establish the diagnosis and to rule out contraindications to surgery. In patients with coronary artery disease, extensive diagnostic procedures do *not* constitute good medical management and actually may be dangerous.

Such usually superfluous procedures as the electrocardiographic exercise tolerance and anoxemia tests should be performed only when the diagnosis is in doubt. In a patient with a critically compensated coronary circulation, undue stress may produce catastrophic consequences. Obviously, in a patient with electrocardiographic evidence of old infarction, such tests are contraindicated. Furthermore, in a patient with typical symptoms, a negative test in no way alters the diagnosis.

The preoperative hospital stay should be as short as possible. Exhausting tests are particularly contraindicated on the day before operation. Anxiety and apprehension on the part of the patient appear to have a specific deleterious effect; such patients have a greater operative risk, presumably associated with the lowered fibrillation threshold of the heart.⁴ Operation should not be performed unless undue apprehension is allayed.

Operative Mortality

Of the 225 patients operated since January, 1951, there have been eleven deaths associated with surgery (two during operation, nine in the early postoperative period), for a total mortality of less than 5 per cent. Careful selection of patients and improvements in medical and surgical management have resulted in a progressive lowering of operative mortality, as evidenced by a recent series of 100 consecutive patients operated in which the only mortality occurred in a salvage case just prior to his discharge from the hospital. At least thirty of these 100 were salvage cases. However, in every instance, symptoms had become fairly stable for a few months prior to operation. Recognition of the limitations of operation has prompted judicious delay in seriously ill patients. Certainly, if a catastrophe is imminent, an ill-timed operation will only hasten it. A delay of a few months permits time for stabilization and greatly enhances toleration of operation and the achievement of a good result.

Course of Patients After Operation

The immediate postoperative course is usually remarkably uneventful, even in those patients who appeared severely ill before operation. Rarely, does the patient complain of pericarditis pain (even though the postoperative electrocardiogram most frequently shows such a configuration). Small left pleural effusion occurs often, but only rarely requires thoracentesis. Evidence of pericardial effusion is rare. In no case has long-term follow-up revealed evidence of deleterious effect of the operation itself. Compression of the heart by a pericardial scar has not occurred.

In approximately 25 per cent of the patients there is almost immediate improvement in symptoms, so that a few days following operation they volunteer the observation that a given amount of exertion no longer causes pain. Generally, following discharge ten to fourteen days after operation, patients are encouraged to return to at least part-time work in four to eight weeks.

In the great majority of patients there is progressive improvement over a course of one to six months after operation. Occasionally, a patient may show no improvement for a few months followed by a period of rapid and dramatic subsidence of symptoms.

Long-term follow-up of the first 100 patients alive at this time reveals a very significant observation. At least fifteen of them have had one or more severe "attacks" requiring hospitalization. However, in only three instances was there definite evidence of transmural myocardial infarction. In each case the patient recovered and eventually returned to work with no worsening of his symptoms. The other twelve patients have had one or more bouts of severe precordial pain (one patient has had five) associated with transient T wave changes in the electrocardiogram. Usually, the pain subsided rapidly and they returned to work in one to four weeks.

In only ten per cent of the patients did long-term follow-up reveal no improvement. However, in some of these there were such complications as severe narcotic addiction, psychoses, and cerebrovascular accident.

Remarkably enough, three of the patients who had evidence of early congestive heart failure prior to operation appeared to be much better compensated after operation. One of these, who had previously required weekly mercurial injections, has now gone eight months without injection.

Unfortunately, the very nature of coronary artery disease is such that so-called *objective* methods for evaluation of medical or surgical treatment are of little value. Reliance on the electrocardiogram or ballistocardiogram is unrealistic. Generally speaking, each patient serves as his own control.

Unusual Manifestations of Coronary Heart Disease Relieved After Operation

Of particular interest is a group of patients having, in addition to the common symptom of coronary heart disease, certain unusual manifestations.

1. Ventricular premature beats. In approximately 5 per cent of the patients operated, ventricular premature beats played a prominent role in the patient's symptomatology. Following operation, this annoying arrhythmia is no longer present or is at least less frequent in most of the patients previously demonstrating it.

2. Reduction or absence of arterial pulses particularly in the left arm. A significant number of patients gave a history of "poor circulation" associated with the clinical onset of coronary heart disease. This was usually manifested by coldness of the extremities. One patient in particular, complained of coldness of the left arm and hand. There were no palpable arterial pulses in the left arm and no blood pressure reading could be obtained in that arm for two years prior to operation. On the day following surgery, good pulsations and a normal blood pressure reading were obtainable from the left, and have continued for the year subsequent to surgery.

3. Sensory changes in the hands. This was particularly well demonstrated in a forty-two-year-old man with severe, progressive angina for three years. For two years before operation this patient noticed a diminution of sensation in both hands, more marked in the left. The sensory disorder was such that he dropped objects from his hands, especially sheets of paper which he could not feel. Examination of the hands and arms showed diminution of light touch, pin point pain and temperature. Following operation on the heart these sensory changes completely disappeared. Again, this is suggestive evidence of causal relationship between myocardial ischemia, sensory changes in hands and arms, reduction of ischemia by operation and return of normal sensation.

4. Shoulder-hand syndrome. This distressing syndrome was particularly annoying in a fifty-five-

year-old male patient following a massive anterior myocardial infarction. In the interval after the infarct, he developed fixation of his shoulders and arms so that they could not be elevated. The patient did not have sufficient mobility to dress himself and he was scarcely able to feed himself. The muscles of the shoulder girdle had become atrophic. Physiotherapy failed to produce improvement. Motion was painful. Following surgery for coronary heart disease, physiotherapy was again given. Marked improvement followed. Within a few weeks he could elevate his arms and motion was not painful. Eventually, he had complete return of function.

Longevity

Long-term follow-up has been carried out on the 137 consecutive patients discharged over a period of six months to five years ago (average: two years since operation). The expected mortality in such a group over this period would be 30 per cent or forty-one dead.⁵ Actually eighteen are known or assumed to be dead, a mortality of 13.1 per cent. Thus, even at this relatively early period, life expectancy can be shown to be increased by operation. Since operation does not prevent the occlusive process in the coronary arteries, a period of symptomatic improvement may be terminated by overwhelming occlusion and death. Such was the case in 50 per cent of the patients who died six months to five years after operation.

Present Status of Operated Patients

Of the 100 consecutive patients who were alive and could be evaluated over a six-month to five-year follow-up period, forty-five are completely free of heart pain. Another forty-five claim that they have considerably less pain than before operation. Thus, 90 per cent have symptomatically excellent results.

By the same token, forty-two are able to work with no limitations, while forty-eight are better

able to work with some limitations. Thus 90 per cent are economically productive. (Prior to operation only 45 per cent had been able to work half-time or more.)

Summary and Conclusions

The Beck operation for coronary artery disease is a safe and effective method for providing a more adequate distribution of arterial blood supply to the heart. Operation is indicated in patients with clinical evidence of coronary heart disease unless there is a specific contraindication. The operation should not be considered as merely a salvage procedure. Best results are obtained by operating early in the course of the disease.

In a consecutive series of 100 patients operated, only one died prior to discharge. The over-all mortality for 225 patients operated since January, 1951, is less than 5 per cent. Long-term follow-up reveals a significant increase in longevity for operated patients. Furthermore, 90 per cent were back at full-time or part-time work with little or no limitations.

In view of the proved effectiveness of the Beck operation for coronary disease, the demonstration of a very low operative mortality removes the operation from the category of salvage procedures and justifies its early application to a majority of patients with coronary disease.

NEW ABSTRACT PERIODICAL ISSUED

The first issue of an abstract periodical, *Cardiovascular Diseases*, was announced in June by the Public Health Service and the Excerpta Medica Foundation. The new journal, which will be published by the Foundation, will provide a means through which scientists interested in heart research can keep abreast of the literature, now a difficult task because of the increasing number of scientific publications in this field.

A grant of \$28,750 for the first year was made to the Foundation by the National Heart Institute of the

Public Health Service on recommendation of the National Advisory Heart Council.

Leading cardiologists and scientists serve on the Advisory Board of the publication and recommend type of coverage and the journals to be abstracted. The Board, appointed by the Excerpta Medica Foundation, will have approximately forty members, nine from the United States. About 7,000 abstracters throughout the world will contribute capsule versions of heart literature from approximately 1,800 selected journals.

Brain Tumors

Practical Approach and Classification

WINCHELL McK. CRAIG, M.D.
HENRY W. DODGE, JR., M.D.
HENDRIK J. SVIEN, M.D.
Rochester, Minnesota

IT IS always difficult to present hard and fast rules in differentiating between benign and malignant lesions in any portion of the body. To present this subject fairly as regards lesions of the brain, let us consider them in relation to malignant lesions elsewhere in the body.

A fairly accurate assay of five-year survivals, which has become an accepted rule of thumb, covering malignant lesions in other portions of the body than the brain, has been given to us by Dr. Dockerty of the Section of Surgical Pathology of the Mayo Clinic, and is presented in Table I.

We have attempted to evaluate malignant lesions of the brain in the same manner, and have graded them according to cellular differentiation. This was first attempted in 1933 during a symposium, "Cancer Is Curable," at the meeting of the American College of Surgeons.¹ More recently, Kernohan, Mabon, Svien and Adson have followed through with a more detailed evaluation of the subject and have applied the grading both in fixed sections and fresh frozen sections. Kernohan and Dockerty at the present time are examining all tumors either biopsied or removed in the neurosurgical operating rooms, and we neurosurgeons find it helpful in designing our operations and giving a more concrete prognosis.

During the recent war, we found that pathologists who were acquainted with this system of grading tumors and who were not well versed in neuropathology gave us an adequate pathologic evaluation of brain tumor. Regardless of the neuropathologic nomenclature, the observation and grading of gliomas of the brain were helpful in giving a diagnosis and especially a prognosis.

Neurosurgeons are faced with the problem of quick diagnosis in many hospitals which have no

neuropathologist, but have qualified general and surgical pathologists, and we think the grading of gliomas is a practical solution to the problem.

TABLE I. FIVE-YEAR SURVIVAL RATES OF PATIENTS WITH TREATED MALIGNANT TUMORS

Location or Type of Tumor	5-Year Survival, Per Cent
Breast	45
Uterine cervix	48
Uterine fundus	75
Stomach	25
Gallbladder	10
Pancreas	10
Colon (left)	35
Colon (right)	50
Lungs	15
Ovaries	30
Testes	35
"Melanomas"	20
Bone (osteogenic sarcoma)	18

It is with the idea of simplifying the pathologic diagnosis and supplying the neurosurgeon with early information regarding the nature and degree of malignancy that we are presenting this concept.

TABLE II. FREQUENCY OF THE VARIOUS TYPES OF INTRACRANIAL TUMORS

Type	Per Cent	Type	Per Cent
Glioma	41	Craniopharyngioma	4
Pituitary adenoma	15	Chordoma (dermoid and epidermoid)	2
Meningioma	20	Metastatic tumor	4
Acoustic neurinoma	11	Granuloma (tuberculous, etc.)	1
		Hemangio-endothelioma	2

The frequency of the various types of intracranial tumors is given in Table II. Pathologically, brain tumors can be conveniently subdivided as follows: (1) tumors of the envelopes of the brain (meningiomas, sarcomas, and so forth); (2) tumors of special structures (pituitary adenomas, pinealomas); (3) tumors arising from heterotopic rests (epidermoids, dermoids, craniopharyngiomas, chordomas); (4) tumors arising from cranial nerves (neurofibromas); (5) tumors

Presented at the Minnesota Academy of General Practice, St. Paul, October 17, 1956.
Drs. Craig, Dodge and Svien are in the Section of Neurologic Surgery, Mayo Clinic and Mayo Foundation.
The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

arising from vascular tissue (hemangio-endotheliomas); (6) tumors arising from neural elements (gliomas), and (7) metastatic malignant lesions.

Any question of benign and malignant tumors of the brain immediately brings up ideas of primary or metastatic tumors (4 per cent), in view of the fact that malignant lesions of the brain may be metastatic from malignant lesions elsewhere in the body. It seemed to us that we could best approach the problem by outlining the benign lesions which occur in the brain.

Epidermoid tumors result from congenital rests. They are characterized by large cysts containing flaky, desquamated epithelium and have the appearance of mother-of-pearl. The capsule of the tumor is composed of epidermis.

Dermoid tumors are similar to epidermoid tumors, except that in addition to the epidermis they also contain sweat glands, sebaceous glands or hairs, or hair follicles. The contents also usually resemble those of epidermoid tumors.

Teratomas are similar to dermoid tumors, except that in addition they have some structures containing mesoderm, such as bone and cartilage. (Actually, dermoids are "simple" teratomas.)

Neurofibromas, neurilemmomas or perineural fibroblastomas arise from cranial and spinal nerves, frequently from the eighth cranial nerve. They are encapsulated and circumscribed and usually grow slowly. They are characterized by regions of degeneration or small cysts, blood pigment, cells containing fat (so-called foam cells), interlacing fibrils and palisading of the nuclei. Usually all these characteristics are present, but sometimes only one or two are seen. Occasionally these tumors simulate meningiomas, on the one hand, or astrocytomas, on the other. They are nearly all benign.

Meningiomas are nodular, rounded, circumscribed and encapsulated tumors, usually vascular and usually slowly growing, although a small number of them are malignant. Frequently they contain concentrically calcified masses called "psammoma bodies," which are so numerous that the tumors are called "psammomas." The cells tend to grow in whorls. Sometimes these neoplasms are very cellular and invade the bone, but mitotic figures are rarely present. When they are present in more than occasional numbers (10 per cent), we classify the meningioma as being malignant and anticipate recurrence.

Meningiomas represent the large operable group

of cerebral tumors. They usually arise from arachnoid villi and most often are situated along the large sinuses of the cranial cavity. They are distinctly encapsulated and, as a rule, do not invade the brain but displace it. Their growth is slow and often requires many years for the production of symptoms. They sometimes produce proliferation of bone in the immediate vicinity, and tumor cells frequently are found to invade the hypertrophied region, a characteristic which offers material assistance in localization of the neoplasms by roentgenologic examination. Meningiomas usually can be removed completely unless they are situated in an inaccessible place; with the aid of the electrosurgical knife many more of these tumors are removed now than formerly. It is essential that the overlying meninges, as well as the invaded bone, be removed to avoid recurrence. Occasionally, malignant changes develop, and the tumor recurs.

Although hemangio-endotheliomas occur most frequently in the cerebellum, they have been found in all parts of the nervous system. A tumor of this sort sometimes occurs as a small tumor nodule (so-called mural nodule) on the wall of a large, smooth-walled cyst. They usually are composed of numerous dilated capillaries with large endothelial cells lining the lumina and large phagocytic cells laden with numerous droplets of fat. These tumors occasionally are associated with hemangiomas of the eye, or of the skin, and with a cystic pancreas or liver or adenomas of the kidneys; in such cases they constitute what is sometimes called "Lindau's disease." Hemangiomas are benign. Hemangio-endotheliomas shade over into hemangiosarcomas and are generally regarded as being of a rather low order of malignancy.

Chordomas arise from notochordal remnants in the base of the skull, the so-called clivus blumenbachii, or from the intervertebral disks. They must be distinguished from chondromas. They are characterized by islands in which there are cords of epithelial-like cells growing in myxomatous matrix. The cells and their nuclei usually are vacuolated and have a foamy appearance (physaliferous cells). In the cytoplasm the vacuoles contain mucus and glycogen, and also a proglycogen which does not dissolve in water. Chordomas rarely metastasize, but they are very prone to recur.

Pituitary tumors include neoplasms which arise

from the three primary structures of the pituitary gland. The chromophobe adenoma usually is responsible for the hypopituitary syndrome, whereas the chromophil adenoma is found in cases of hyperpituitarism. Tumors of the cranio-pharyngeal duct arise from Rathke's pouch. All these and other variations of pituitary tumors are capable of enlarging the sella turcica and of producing suprasellar extension. They usually produce some form of hemianopsia, of which bitemporal hemianopsia is the commonest, but it is obvious that the position and extent of the tumor will cause these manifestations to vary from time to time. They rarely produce papilledema, but frequently give rise to optic atrophy preceded by pallor of either side of the margin of the disk. Choked disks develop only when the tumor extends upward and posteriorly into the third ventricle, resulting in block of one foramen or both foramina of Monro. The commonest tumors which produce such symptoms are tumors of the craniopharyngeal pouch. Although enlargement of the sella turcica is considered to be pathognomonic of pituitary tumor, it cannot be relied on as an absolute sign, since the posterior clinoid processes, and even the sella turcica, may be eroded in the presence of increased intracranial pressure caused by cerebral tumors in other locations. Therefore, the diagnosis of tumor of the pituitary body usually is based on clinical hypopituitarism or hyperpituitarism plus enlargement or erosion of the sella turcica, perimetric field defects, changes in the ocular fundi or more than one of these features. Most of these tumors can be removed by the intracapsular method.

Dermoids and similar tumors represent a group of encapsulated tumors which often can be removed, depending on their size and exact position. Most of these present roentgenologic shadows which serve to supplement neurologic data in localization of the tumor. Pinealomas are an exception, chiefly owing to their location.

A surgeon dealing with malignant lesions desires to determine two facts from the microscopic examination of the tissue with which he is confronted: First, what is the kind of tumor? Second, what is its relative malignancy? The surgical procedure is often determined or modified by this knowledge. In Broders' method of grading carcinoma, the general surgeons have been provided with such a measure of the degree of malignancy.

The neurosurgeon, however, has not had this advantage, inasmuch as no system of grading has been applied to brain tumors. Neuropathologists have differentiated benign and malignant meningiomas and adenomas of the pituitary. However, with the present classification of the glioma group, which constitutes 41 per cent of the brain tumors, the neurosurgeon is confronted with many subdivisions, and obtains only a relative index of their malignancy. It was believed that a simplification of the present classification of the gliomas together with the grading of the degree of malignancy within each group would be highly advantageous to the neurosurgeon. Our glioma group was re-studied with this thought in mind. The concept has been applied, which is rather universally held by general pathologists in dealing with carcinoma elsewhere in the body; namely, that malignant change represents an anaplastic transformation of adult cells. The neural tissue of the brain is made up of four different types of cells, and consequently when the concept of anaplastic change is applied to the study of gliomas there are five types arising from these cells: namely, (1) astrocytoma, (2) ependymoma, (3) oligodendroglioma, (4) medulloblastoma, and finally (5) a debatable neoplasm—neuro-astrocytoma.

When considered histologically from the anaplastic concept, the astroblastoma and glioblastoma multiforme are merely more malignant forms of astrocytoma. Likewise, the ependymblastoma has been shown to be merely a more malignant form of ependymoma. It was determined histologically that malignancy within each of these five groups could be conveniently graded from 1 to 4. Correlation studies between grade of tumor and postoperative survival period substantiate these conclusions.

The derivation of the medulloblastoma has not been definitely established, and it is believed to be in a class by itself. This glioma has a relatively constant histologic structure, and practically all examples have the attributes of a grade 4 neoplasm. The poor results of treatment bear this out.

The suggested modification of the classification of gliomas is presented in Table III.

Data on astrocytomas are given in Table IV.

Astrocytomas, grade 1, are slowly growing neoplasms; they are firm and usually nonencapsulated tumors. They are composed of fairly normal astrocytes with numerous well-formed glial

TABLE III. POSTOPERATIVE SURVIVAL

	Grade	5-Year Survivals, Per Cent	Average Survival, Months	Longest Survival, Years
Astrocytoma	1-2	47.5	76 +	13 +
Medulloblastoma	4	12.6	15	7 +
Oligodendroglioma	1-4	4.0	66 +	15 +
Ependymoma	1-4	3.7	25 +	14 +
Pinealoma	1-4	2.0	18 +	—

TABLE V. EPENDYMOMA ACCORDING TO GRADE
OF MALIGNANCY: 57 CASES

Grade	Cases	Average		
		Age, Years	Duration of Symptoms, Months	Postoperative Survival, Months*
1	30	26.1	19.8	77.0
2	8	28.5	19.6	37.7
3	9	21.0	9.0	18.2
4	10	31.3	9.1	10.1

*Since some of these patients were living at the time of this study, these figures represent minimal estimates of the average postoperative survival.

fibrils, which often form vascular feet. The group includes the polar spongioblastomas of the older terminology. These are confusingly similar to neurofibromas.

Astrocytomas, grade 2, also are slowly growing neoplasms, but are somewhat more pleomorphic than the grade 1 tumors. The cells are slightly larger, glial fibrils are fewer and shorter, and the vascular processes are short and heavy.

Astrocytomas, grades 3 and 4, formerly designated "glioblastoma multiforme," are among the most malignant of all gliomas and comprise 57 per cent of the group. They have multiform characteristics, both grossly and microscopically. Histologically, the tumors usually are characterized by giant cells, by mitotic figures and by variation in the size of the various cells and their nuclei. Frequently there are vessels with marked proliferation of the lining endothelial cells, sometimes progressing to complete or almost complete occlusion of the lumen of the vessels; hence, regions of necrosis or cysts are found.

Data on ependymomas are given in Table V.

Ependymomas, grades 1 and 2, are very slowly growing tumors, arising as a rule from the ependyma of one of the ventricles of the brain or from the central canal of the spinal cord. Sometimes they are circumscribed and appear to have capsules so that they can be enucleated. The histologic picture frequently features papillary architecture, and the tumor cells also tend to form canals similar to the central canal of the spinal cord.

TABLE IV. ASTROCYTOMA ACCORDING TO GRADE
OF MALIGNANCY: 161 CASES

Grade	Cases	Average		
		Age, Years	Duration of Symptoms, Months	Postoperative Survival, Months*
1	32	33.9	20.8	73.6
2	38	38.2	11.2	23.8
3	37	40.4	11.8	11.5
4	54	42.6	7.3	6.6

*Since some of these patients were living at the time of the study, these figures represent minimal estimates of the average postoperative survival.

Ependymomas, grades 3 and 4, present a histologic picture in which the characteristic ependymoma structure is less and less clearly defined as the grade of malignancy increases. Variations in size and shape of cells and their nuclei and mitotic figures are present. These tumors parallel astrocytomas, grades 3 and 4, in rapidity of growth.

Oligodendrogliomas, grades 1 and 2, have a tendency to degenerate and to become cystic, and often contain deposits of calcium, which can be seen on roentgenologic examination. These tumors are characterized histologically by their unusual honeycombed appearance of small clear-looking cells. It is very difficult to demonstrate stainable cytoplasm or processes in these cells. The nuclei are very small and look like lymphocytes lying in holes.

Oligodendrogliomas, grades 3 and 4, may be among the most malignant neoplasms of the nervous system. They simulate oligodendrogliomas, grades 1 and 2, except that the cells of these tumors are larger than those of oligodendrogliomas, grades 1 and 2, and contain mitotic figures. Some cellular cytoplasm can be seen and the nuclei are large.

Ganglioneuromas, gangliocytomas, gangliogliomas or neurocytomas (neuro-astrocytomas, grade 1) are rare. They are characterized by a basic "astrocytoma" appearance plus the presence of well-formed ganglion cells which contain Nissl bodies. Silver nitrate may be employed to demonstrate the processes of these ganglion cells.

Medulloblastomas usually are found in children in the midline of the cerebellum. They are very malignant neoplasms (grade 4), and they tend to implant themselves in the ventricles or meninges. In spite of the high degree of malignancy of these tumors, mitotic figures may occasionally be hard to find. Microscopically, the tumor cells have oat-shaped nuclei and a small amount of cyto-

plasm which tends to taper at one end. The cells grow in small clusters and may produce rosettes.

In all reported series of brain tumors, the incidence of medullo-epithelioma has been exceedingly low and in many series no tumor of this type has been found. At the Mayo Clinic, those tumors that had been classified as medullo-epithelioma were critically restudied and it was found that they were either ependymomas, grade 4, or medulloblastomas; therefore, we have eliminated this tumor entity from the classification of gliomas.

Sarcomas are much rarer than at one time they were supposed to be. Usually, they are highly malignant tumors probably arising from the connective tissue around the blood vessels. There is a sharp line of demarcation from the surrounding portion of brain, which is softened and degenerated around the tumors so that they seem to be encapsulated. The lesions occur most commonly among young adult persons.

Metastasis of carcinomas to the central nervous system is fairly common. The primary lesion is usually found, however, before any neurosurgical intervention is undertaken, and this fact may be considered adequate reason for not attempting such measures. Frequently there are metastatic growths elsewhere. When the tumor in the brain is the only demonstrable metastatic lesion and the primary carcinoma is small and slowly growing, enucleation of the cerebral lesion is justified, since it sometimes relieves intracranial pressure for a prolonged period.

Metastasis to the central nervous system may take place from almost any organ of the body, but the lungs are the most frequent primary seat of such a neoplasm. In the Mayo Clinic it has become a routine procedure to obtain roentgenograms of the thorax in all cases in which a neoplasm of the central nervous system is suspected. This procedure has disclosed most carcinomas of the lungs, and in doubtful cases bronchoscopic examination has usually settled the question. In spite of these precautions, some patients are operated on for metastatic tumors of the brain in the belief that the lesions are primary. The primary tumor may be hidden by the shadow of the clavicle, the heart, or the hilus of the lung. Often pulmonary symptoms are not present. In one case, tuberculosis was considered and subsequently healed tuberculosis was found with a carcinomatous lesion growing nearby.

It is important to distinguish metastatic carcinomatous lesions of the central nervous system from primary neoplasms of the brain. Sometimes such distinction is made with difficulty, particularly when very small portions of tumor have been removed at operation. It is especially difficult at times to differentiate the so-called oat-cell variety from medulloblastoma unless the age of the patient and the situation of the growth are taken into consideration. If, however, attention is given also to location, the number of mitotic figures, the size of the nuclei, and the amount and arrangement of the cytoplasm, a correct diagnosis can be made.

The surgical treatment of brain tumors has made rapid progress in recent years, with the improvement in cerebral localization and surgical technique. The introduction of antiseptic substances, asepsis and methods of hemostasis has reduced surgical hazards and has lowered the surgical mortality rate. The development of surgical technique with the aid of the electrosurgical knife and the electrocoagulation needle has made it possible to remove tumors which previously would have been inaccessible. By these means also it has become possible to effect subtotal resection of extensive gliomas and even lobectomy when it is advisable. Cerebral localization of new growths has made much progress with increasing knowledge of the functions of the brain. Pneumoencephalography and pneumoventriculography have contributed to the localization of brain tumors. Neuropathologists have given to the medical profession a better understanding of the life cycle of the various types of tumors than they had formerly. They have supplied information to the neurosurgeon in order that he might exercise improved judgment in the surgical treatment of brain tumors. Since tumors originate from all the structures within the brain, and from the blood vessels, the meninges and the nerves, it is apparent that the size of the tumor, its situation, the degree of its encapsulation and invasion of adjacent structures, its vascularity and its degree of malignancy will vary.

Comment

In approaching an analysis and evaluation of malignant lesions of the brain, we feel very strongly that a correlation can be made with malignant lesions elsewhere in the body. In view of the fact that gliomas are primary malignant tu-

mors arising within the brain substance and constitute 41 per cent of all intracranial tumors, it might be well to discuss them first. In the early days of neurologic surgery, all gliomas were looked on as having the same origin and the same degree of malignancy. It was not until Bailey and Cushing³ presented their classification that the origin, course and malignancy of the tumors were better understood. Previous to this time, there had been sporadic and individual attempts to classify these tumors with regard to their rate of growth, their malignancy and the postoperative longevity of the patient. The neuropathologists have accepted Bailey and Cushing's classification, and a great deal of valuable information has resulted from follow-up studies on these cases.

However, during the war it was brought to our attention that those of us who had been operating with associates in neuropathology needed some clarification of malignancy of brain tumors. In approaching this problem to orient general pathologists with regard to relative malignancy of the tumors and help them fulfill their responsibilities with regard to the surgeon's approach, we asked Dr. Dockerty to give us a five-year survival rate on cancer of the breast, uterine cervix, uterine fundus, stomach, gall bladder, pancreas, colon (left), colon (right), lungs, ovaries, testes and bone, and on "melanomas." These tumors located elsewhere in the body have been followed and graded. For some time we have been attempting to grade our primary tumors of the brain, and for this reason we have divided them into five classifications: astrocytoma, ependymoma, oligodendroglioma, neuro-astrocytoma and medulloblastoma. In only four of these have we been able to grade the tumors with regard to their malignancy on the basis of cellular differentiation and to correlate the preoperative symptoms as well as postoperative longevity. In the astrocytoma group, 161 patients have been followed. In this group there were thirty-two cases in grade 1, thirty-eight cases in grade 2, thirty-seven cases in grade 3, and fifty-four cases in grade 4. The interesting thing about this survey is that the average age of patients with grades 1 and 2 was between thirty and thirty-nine years and that of patients with grades 3 and 4 was between forty and forty-nine years. The duration of symptoms was longer in grades 1 and 2 than in 3 and 4, and the postoperative survival corresponded.

Fifty-seven cases of ependymoma were fol-

lowed: thirty cases in grade 1, eight cases in grade 2, nine cases in grade 3, and ten cases in grade 4. The age differentiation was not as marked as in the previous series, but there was a very interesting correlation between the preoperative duration of symptoms and postoperative survival. One interesting observation with regard to this group is the fact that more than 50 per cent were in grades 1 and 2 and had a much better prognosis than in grade 4.

The frequency of the various types of intracranial tumors also brings out some of the relative percentages which influence our thinking with regard to mortality and longevity in cases of tumor of the brain. While 41 per cent of the intracranial tumors are gliomas and 4 per cent are metastatic tumors, 15 per cent are pituitary adenomas, 20 per cent are meningiomas, 11 per cent are acoustic neurinomas, 4 per cent are cranio-pharyngiomas, 2 per cent are chordomas and dermoids, 1 per cent are granulomas and 2 per cent are hemangio-endotheliomas.

Thus, when a diagnosis of glioma of the brain is made it does not necessarily mean that the patient's death warrant has been signed any more than when a diagnosis of cancer of the breast or cancer of the lung is made. Since the gliomas have been studied microscopically and graded in the same manner as cancer elsewhere in the body, the surgeon at the operating table has been able to tell whether or not to approach the tumor radically, removing a section of the brain containing the tumor, or in a palliative manner in which the tumor is removed *in situ*.

This approach to grading of gliomas has been accepted by pathologists and neurosurgeons in a surprising number of medical centers. When one thinks of brain tumors, one must differentiate between the benign and the malignant, and secondarily one must consider malignant lesions of the brain in the same manner that one considers malignant lesions elsewhere in the body and treat them in a like manner.

Resuscitation of the Newborn

R. O. BURMEISTER, M.D.
Saint Paul, Minnesota

INASMUCH as I devote approximately half my time to the practice of anesthesiology and half to general practice, I have the recurring opportunity, as you do, to experience some of the problems in general practice in which knowledge and experience in the field of anesthesiology aids in obtaining a quicker or better solution to the problem at hand. With this dual concept in mind, that is as a general practitioner and as an anesthesiologist, I am going to present a commonly occurring problem—that of the newborn infant requiring resuscitation.

Let us be academic for a moment and begin by formulating a definition of what we mean by the infant needing resuscitation. Any newborn infant who does not initiate upon birth and maintain thereafter a normal respiratory rate rhythm and minute volume, and thereby shows cyanosis in any degree, is an infant who requires resuscitation. Resuscitation then becomes the employment of any means necessary to restore the respiratory deficiency to normal. This may range from the simple administration of oxygen to the employment of a number of mechanical contrivances in addition. These devices may be primarily for clearing the airway of any obstruction, or for promoting the passage of oxygen to the site of gaseous exchange, the alveoli, or for both purposes.

Before we consider in more detail the means of treatment, and outline a program of action which should become habitual for all of us, let us review some of the causes of the respiratory difficulty in the newborn infant. All causes can be listed under two headings, the central and the peripheral causes. When respiratory depression or absence is due to central involvement there is a hypofunction or absence of function of the respiratory center in the medulla. This may be drug induced, or may be caused by obstetric difficulties in the mother, with severe and prolonged periods of hypoxia or anoxia in the unborn infant. Such maternal-infant accidents are represented when

we are faced with placenta previa, abruptio placenta, prolapsed cord, and difficult deliveries as a result of maternal pelvic dystocia with resultant cerebral trauma and/or hemorrhage in the baby.

A second group of causes of respiratory difficulty is present when the etiologic factor is a peripheral disturbance. This may be a congenital malformation in either the upper or lower respiratory passages. As examples, we can list cleft lip and palate, laryngeal malformations and growths, tracheo-esophageal fistulae, and obstructive tumors in the upper and lower tracheobronchial tree. Atresia of major structures at any level in the respiratory tract may be the cause of severe difficulty. These conditions are uncommon. However our most commonly encountered problem in this group of peripheral causes is the mechanical obstruction of the upper and lower tracheobronchial tree by amniotic fluid, blood, and debris.

Before taking steps to initiate definitive treatment, one must take a few moments to survey the cause or causes of the respiratory difficulty. Momentary observation of the deficiency respiring infant will give us a good lead as to what major group of causes is to be considered. If we have a limp, flaccid and pale or ashen-cyanotic infant with absent or markedly deficient respirations, central involvement is strongly suggested as the primary cause, though other factors may also be present. If, on the other hand, we are presented with a normotonic or hypertonic, lividly cyanotic child with respirations that are labored and showing sternal and intercostal retraction with respiration, we are probably dealing with any of the causes that produce obstruction high or low in the respiratory tract itself. Being cognizant of the potential difficulties with the infant when a long and difficult labor and delivery has occurred, or when fetal distress has been present from placental or cord accidents, will quickly direct our attention to the proper procedure in attempting to resuscitate that infant.

Now let us turn our discussion to the manner of active resuscitation of the improperly respiring

Presented at the Minnesota Academy of General Practice, Saint Paul, Minnesota, October 17, 1956.

infant. As in any treatment program in any abnormal situation in medicine, here also definitive treatment is dependent upon etiology, but a few basic principles must be carried out in all instances. Perhaps the basic axiom in all anesthesiologic problems and all instances of respiratory distress is the administration of adequate oxygen supply. The means and manner of supplying this oxygen will vary with given conditions. A second basic axiom, and not infrequently of first importance, is the establishment of a patent airway, if it be impaired, through which the oxygen supply may be administered.

The use of adjunctive measures and mechanical means will depend upon the conditions existing in the infant. Let us take these steps into consideration in the sequence in which we discussed the causes. Obviously, if the difficulty is due to central depression and interference with the function of the respiratory center as a result of cerebral malformations or birth injuries, such as cerebral hemorrhage, and tentorial tears, our only recourse is to supportive treatment, that is, attention to a patent airway and administration of a relatively high oxygen concentration through it. In this situation the prognosis is very grave, and only if the damage is minimal does the infant have much chance at survival. If, however, the depression of the medullary centers is drug induced, and this usually is from narcotics given in too large or too recent doses to the mother, or is due to severe and prolonged degrees of anoxia as a result of placental accidents, active resuscitative measures and the administration of certain specific counter agents will restore a normal respiratory pattern. We will discuss later the manner of active support of respirations, but for a moment I would like to digress and discuss at this point one of the most important drugs now available to us to counteract drug depression. This agent is N-allyl normorphine hydrochloride which is marked under the trade name "Nalline." It is a morphine analogue or derivative and is subject to all the regulations of the Harrison Narcotic Act. It is packaged in a stable solution form in a one cc. ampule containing 5 milligrams, which is the average adult dose, and more recently in a one cc. ampule containing 0.2 milligrams, which is the newborn infant dosage. Nalline is an antagonist to morphine, dilaudid, codeine, demerol, dolophine, levo-dromoran, and most of

the other synthetic analgesic drugs. It does not antagonize the action of the barbiturate and barbiturate-like drugs. Its mode of action is believed to be as a more powerful competitor than morphine and like agents for the cells of the respiratory center, and in this manner displaces the morphine molecule from its hold on the respiratory cell. Inasmuch as Nalline does not produce the depression that the competing drugs do, its displacing the latter restores the functioning power of the cell. While we are talking on the level of the function of the respiratory cell it might be well to say a few words about and against the use of the so-called analeptic drugs such as caffeine sodium benzoate, metrazol, and coramine. The mode of action of this type of agent is a simple stimulation to overactivity of the respiratory cell. If we have a cell that is already suffering an oxygen deficiency and then stimulate it to a dying gasp, as it were, and exhaust its remaining oxygen supply by that activity, we will end up with a cell that is more depressed and perhaps even permanently damaged. Thus we can explain the fallacy of using analeptic agents as respiratory stimulants.

To return to Nalline, we can list certain other actions of the drug which shows its antagonism to morphine. It is of no value in relieving pain, and when administered to the addict will produce all the signs and symptoms of the withdrawal syndrome. Its duration of action is very short, probably not more than fifteen minutes. The mode of administration may be by the subcutaneous route, intramuscularly, or intravenously by direct injection or in a dilute drip solution. The usual dose is 5 milligrams in the adult or 0.2 milligrams in the newborn infant. When a respiratory depression in the newborn may be anticipated before delivery, Nalline may be given intravenously to the mother in the 5 milligram dose, ten minutes or less before delivery. If the difficulty is not anticipated, the 0.2 milligram dose may be given directly into the umbilical vein after delivery; or if this is not feasible, into the infant's buttock. Repeated doses may be given as indicated. The response in all indicated instances is dramatic, and it has been my personal observation that within a few minutes of administration the great majority of these babies respire deeply, and cry lustily for upwards of an hour, and as a result, attain and maintain an excellent color in a nor-

mal oxygen environment. One must interject a word of caution here relative to the indiscriminate usage of Nalline, for we are told that when it is used in the face of a depression not caused by a narcotic overdosage, a potentiation of the depression will occur. Whether this is more apparent than real, I can't say from experience—for ours has been extremely good with this drug—but I find it hard to believe that we achieve 100 per cent accuracy in our diagnoses. Nevertheless, Nalline is a wonderful addition to our armamentarium; and if you take with you today an awareness of it and its usefulness, one of the salient points of my discussion will have been successfully made. It is a drug that has been available to us for some time, but it has not been exploited to us by detail men and in our daily stacks of promotional mail, and as a result a surprising number of us have been unaware of its existence.

Specific case illustrations in medicine are invaluable in fixing ideas in our minds, and so I should like to mention briefly two instances in which the action of the drug could be demonstrated. In the first case, the drug was not used when it would have been the ideal treatment instead of the means that was used, and would have avoided the resultant embarrassing situation that developed. In the second case, Nalline was employed with a rapid termination of what was becoming an alarming situation. Both these cases were in adults and both were in recently delivered mothers, but the drama of narcotic drug depression and its correction is vividly shown.

Case Reports

In the first case, the patient was a multigravida admitted to the hospital close to the hour of midnight, well advanced in the first stage of labor. She was given 100 milligrams of Demerol in the course of preparations for her delivery. Delivery was accomplished in less than an hour thereafter with minimal inhalation analgesia. At the close, the anesthetist reported a moderately elevated blood pressure to the attending physician, and in his immediate post-partum orders he prescribed morphine grains $1/6$ if the pressure continued to rise, which it did. Therefore, approximately one-half hour after delivery, the patient was given the morphine as ordered, or approximately one hour and fifteen minutes after she had been given 100 milligrams of Demerol. Within the next hour, respiratory depression had progressed to the point where the rate was down to ten per minute and subsequently

dropped to as low as two and three per minute. The house doctor was called to see the patient, but being unaware of the proper diagnosis or its specific treatment, ordered only supportive measures, which were totally inadequate. By the time the attending physician had been reached again, the situation was extremely grave; and he, being unaware of the antidote indicated, told the nurses to call the fire department resuscitation squad. Thus, we had the spectacle of burly firemen in rubber boots coming into our maternity section in the dead of the night to administer artificial respiration to the patient for several hours until the drug could be detoxified by natural processes.

The second case occurred, again about midnight, in a patient who had just successfully undergone an emergency Cesarean section under Pentothal curare anesthesia. In our sections we use a special technique in which minimal amounts of Pentothal are used and relatively massive doses of curare to the point of almost total paralysis of the mother. Our experience with this technique, in which tensilon is used as a curare antagonist at the close of surgery, had covered some 200 consecutive sections at this time, and practically all patients were breathing normally, were awake and responding lucidly before leaving the operating room. In the case under discussion, this was not so. The patient was extremely restless, not really awake, and she became cyanotic if respirations were not assisted with 100 per cent oxygen. She was given two more doses of tensilon at intervals in the belief this was all due to the curare; but when the situation failed to improve, a complete review of all possible causes suggested that her premedication of 75 milligrams of Demerol might be the factor. She was then given 5 milligrams of Nalline intravenously, and within a matter of minutes her respirations became more normal, her color was maintained without assistance, and her restlessness ceased. Before she was returned to bed, she was awake and responding normally. This latter patient apparently was extremely sensitive to narcotics, and, though an unusual occurrence, certainly fixed in my mind the value of consideration of all factors, particularly narcotic intoxication, as a cause of respiratory depression.

Now let us consider the treatment of respiratory deficiency as a result of peripheral causes. In the presence of congenital malformations and obstructive growths, surgical intervention, such as immediate tracheotomy, may be necessary along with the usual supportive measures, but fortunately, these instances are rare. Far from rare, though, are those instances where obstruction of the respiratory passages is due to cellular debris, amniotic fluid, meconium or blood. Here is where we can have our highest percentage of successful resuscitative efforts by properly cleansing the hypopharynx and upper tracheobronchial tree with

some form of suction and thereafter combatting anoxia by administration of oxygen with manual assistance with a gas machine until a normal respiratory pattern is established. I'm sure all of us can easily recognize the cases which require no more than aspiration of the nasopharyngeal secretions by simple suction, such as with a bulb. For treating the severe cases which require more extensive resuscitative maneuvers, let me describe the resuscitation tray which we have available at all times in our delivery rooms and operating rooms when sections are being done. All equipment on this tray is maintained in sterile condition. On it we have an infant-sized laryngoscope, two different small infant-sized endotracheal tubes with connectors, an assortment of small rubber catheters for suction directly, and polyethylene tubes for endotracheal suction through the endotracheal tube, and the appropriate connectors for hooking up to a gas machine for manual assistance of respiration and inflation of the lungs. As our suction source we use an Emerson resuscitator which can be used for suction and then quickly switched to use for manual administration of oxygen. In a theoretical case, the procedure we carry out is as follows: The hypopharynx is exposed with the aid of the laryngoscope and by means of catheter suction, it, and the nasopharynx, is cleansed of all accumulated secretions. The epiglottis is then brought into view and elevated with the tip of the blade. This exposes the vocal cords and the catheter is then directed between them and down the trachea, and further aspiration carried out. When one is satisfied that the fluid and other material has been removed and the respiratory movements are fairly adequate, oxygen is administered by mask or cone. If respirations are absent or inadequate, the properly sized endotracheal tube is inserted and oxygen administered by manual assistance via the gas ma-

chine. When restoration of adequate oxygenation has been accomplished, one may again aspirate the upper tracheobronchial tree through the endotracheal tube with a polyethylene catheter. When the respiratory response becomes adequate, the endotracheal tube is withdrawn and the infant placed in an oxygen-rich atmosphere until conditions have stabilized at normal levels. In all cases of prolonged or difficult resuscitation, the infant should be placed in a moist atmosphere with oxygen for twenty-four hours or longer as indicated. Alevaire® may be used if preferred. We carry out this procedure of endotracheal aspiration and moist atmosphere as a routine in most of our section cases also, for they are more prone than the vaginally delivered to develop atelectasis and hyaline membrane disease.

It might seem that some of these steps would be difficult to carry out, but direct laryngoscopy in the infant is relatively easy and with very little practice one may become adept at it. A simple review of the anterior position of the laryngeal fossa in relation to the esophageal orifice will correct many of the errors we make in first doing an endotracheal aspiration. I have long felt that this vital maneuver, which is not difficult to master, has been neglected as a technique which should be taught to our medical students. Certainly, there are numerous instances in addition to those mentioned where the ability to carry out direct laryngoscopy and endotracheal aspiration could mean the difference between life and death for one of our patients.

In conclusion, let me emphasize once again three salient points. First, in respiratory problems think first of oxygen; second, remember Nalline as the antidote for narcotic drug intoxication; and, third, have available and learn to use simply equipment for carrying out endotracheal intubation, aspiration and ventilation.

ABOUT CHRONIC DISEASE

The greatest health problem facing the state today is how to expand and improve services and facilities for the mounting number of chronically sick. The increasing urgency of this problem is closely related to the rapid, continuous increase of people over sixty-five years. Older people suffer disproportionately from chronic disease; almost 45 per cent of their illnesses are due to chronic disease.

In 1900 only 22 per cent of the total deaths in Minnesota were among persons sixty-five and over,

while in 1950, 61 per cent of all deaths occurred in this older age group.

In effect, then, the state is confronted with an increasing number of oldsters living longer with their disabilities; an increasing demand for medical and allied medical services and facilities; the continuous heavy cost of such care often producing pauperism in an otherwise economically stable population; and the greater tax burden on a proportionally decreasing taxable population.—*Minnesota's Heath*, January, 1957.

Allergy

A Round-Table Discussion

JACOB BLUMENTHAL, M.D., Moderator
Minneapolis, Minnesota

LOWELL HENDERSON, M.D.
Rochester, Minnesota

ELMER T. CEDER, M.D.
Minneapolis, Minnesota

DR. BLUMENTHAL: An allergy is an altered reaction capacity of the tissues of certain people. It is the altered reaction of their cells to their world about them. Now, of course, it is clear that a definition so inclusive would encompass all altered reactions, pathological and physiological. However, the term allergy has become very markedly restricted in use and concept to that group of altered reactive diseases in which there is a large hereditary factor, the production of specific antibodies called reagins, increased tonicity of smooth muscles, and symptoms of vasomotor origin. But even in this limited sense, it is the pattern of tissue response which is fundamentally important, and the same manifestations may be elicited by a wide variety of stresses and strains and stimuli. Allergy has become integrated into many fields of medicine: dermatology, ophthalmology, pediatrics, internal medicine, and, most certainly, general practice. But in spite of this, we in the field of allergy, have limited our work to the narrow concept of the term, realizing full well that everything that itches and sneezes and wheezes is not allergy. It is at times very hard to make a diagnosis between a true hypersensitive state and other conditions in medicine.

Rather than go into all of the various ramifications, I would like to answer a few of the questions of general interest which have been asked. The first question we should like to consider would be the treatment of hay fever. There has been a lot of controversy recently as to whether the steroids or antihistamines have taken the place of desensitization.

Hay fever is a good starting point because it is the most simple, apparently, of all the allergic conditions. Dr. Henderson will talk on that.

DR. HENDERSON: By hay fever I assume that you mean the seasonal variety that we think of

as caused by pollens of trees in the early spring, grasses in the late spring, and weed pollens in the fall. Hay fever of this simple seasonal type seldom lasts longer than about six weeks in Minnesota, and usually responds very well to the common measures of avoidance of the offending irritant as much as possible, symptomatic treatment, and, if necessary, desensitization. The important thing in avoiding the pollens is staying inside as much as the job or the activities permit. Air conditioning is very good in most of these cases. Going away on a vacation is another way of avoiding it. Unfortunately, the vacation spots are getting farther and farther away, as the pollens seem to be spreading, particularly the ragweed pollens. But as I talk to my patients with hay fever, I put as the No. 1 effort in managing it the avoidance of the pollens in the first place.

The second thing, then, is symptomatic treatment. If the patient has avoided the offending irritants fairly well and still has some symptoms, then the antihistamines are the next thing to consider. As far as the antihistamines are concerned, I have no great preference. There are about half a dozen that I think are fairly good, and it's a matter of trying one or trying another, letting the patient find which one gives him the most help with the least side reactions. Many patients will complain of grogginess on the very antihistamine that seems to stimulate another person. Someone else will get a dry throat, while another person tolerates it very well. An antihistamine which will help one person may be of no help to another. I very often write small prescriptions or give out samples of one or another type, trying to encourage patients to take one for two or three days at a time. They do that until they get one that gives the most help. We have seen no bad effects from antihistamines. I know there are a few instances where there have been reactions, such as bladder symptoms caused by taking antihistamines orally, but we have had no trouble. We use

Presented at the Minnesota Academy of General Practice, St. Paul, October 17, 1956.

other treatments, such as are indicated in the way of cold packs for the eyes, some adrenalin, and boric acid eyedrops, and anything along that line. We have seen very little help from antihistaminic eyedrops or antihistaminic nose drops. Now, if those two things aren't sufficient to enable a person to get along fairly well, the third thing is desensitization. We try to get the patient to come in a few weeks ahead of the pollen season to start the desensitization program. Many of them will bring up the question, "How about the steroids? Can't I avoid all this by just taking the steroids?" And our answer definitely is *no* to every one of these patients, because it just doesn't make sense to take as potent a medicine as the steroids for something which, at the most, is usually a nuisance type of thing, particularly if the patient will observe some of these common sense measures.

Now, we have had a few cases where everything else has been done—avoidance of pollen as much as possible, air conditioned living quarters, antihistamines, desensitization, following our instructions totally—and still the patient was miserable. Then there are some of the local businessmen who felt they couldn't get away but have done everything else. To some patients of this type we have given steroids for about four days. Usually this is in the ragweed season, and by about the 28th or 29th of August they are really up against it. We give them steroids until about the first, second or third of September. Usually within another week the pollens begin to subside anyway. I think that we have treated a total of about fifteen different patients like that, none of them getting steroid therapy for more than about six days at the most. These have all been patients who have tried every other type of treatment. They understood that the steroids would be stopped after three to five days, even if the symptoms did return. On that basis we have gotten along very well. I will say that we considered all contraindications and didn't give the steroids to patients with any of the usual contraindications.

DR. BLUMENTHAL: Thank you, Dr. Henderson. I agree essentially with what you have just said. A desensitization that is well done will give about 80 or 85 per cent very good results. About 10 per cent will not get results from desensitization. I feel it is the method of choice in the serious hay fever victims, the ones that are not

getting relief from the antihistamines. My experience with the antihistamines is that with sufficient dosage the patient will go to sleep. If not enough is given, nothing happens. My experience has been that desensitization usually has to be resorted to unless the patient can avoid the causes. It is very hard for a patient to get away, as in ragweed pollinosis, for six weeks unless he happens to be in an unusual position.

The next question is really a very difficult one—at least I think it is. It is in the form of two questions: Is eczema in the adult due to a food allergy—how can one handle it; is infantile eczema an allergenic phenomenon?

DR. CEDER: These are certainly two very difficult questions, particularly the question about infantile eczema being an allergic phenomenon. Many papers have been written by dermatologists, pediatricians, and allergists on the investigation of the allergic etiology in this disease. Of course, one first must differentiate between what we call atopic eczema and seborrheic dermatitis, but that cannot be done in the short time allotted. But let us assume that the child is what we call an eczematous, non-seborrheic child, coming from an atopic family with either hay fever or eczema in the background, and that the eczematous areas developed soon after birth over the arms and may even be extensively widespread. The general consensus of the American Academy of Dermatology is that they feel that the management of atopic eczema is chiefly topical. The role of foods in preventing, controlling, and curing this condition is quite equivocal. Dr. Louis Webb Hill, a prominent Boston pediatrician, who has been a student of the condition for a number of years, has written extensively on the subject and has come to believe that he cannot control eczema by eliminating foods alone. For example, the skin tests that are performed by passive transfer usually show a marked reaction to egg albumin, wheat, and milk, chiefly cow's milk; and the children are generally placed on substitutes for those. But in my experience, I do not believe this is too important. I can generally bring them under control with topical preparations within a few weeks, and treat them with the normal pediatric diet.

Now, the question has been raised that there may be some environmental allergy, particularly in the inhalants. Dr. Stephan Epstein of Marshfield, Wisconsin, has gone into that. He feels

that is quite a prominent allergy problem, probably more so than in foods. On the other hand, he feels that he can control infantile eczema by adjusting the diet as well as the atmospheric or environmental factors.

As far as adult eczema is concerned, this same infantile eczema generally will go on into adult life. It's quoted that about 30 per cent of these children outgrow their eczema in the first six years of life and become nonreactive. Some will have a period of quiescence or latency between the ages of ten to sixteen, we will say; then they will have another exacerbation. These represent about 20 per cent. This recurrence will continue on into adult life, usually up to about thirty years of age. Now, the reason that I mention this is that if this were an allergy, would there be these intervals of freedom from reactive allergies in a certain age group, with recurrences later? Furthermore, it's quite a common observation that this type of eczema, the so-called atopic eczema, is much more prevalent in winter than in summer. As a matter of fact, approximately 90 per cent of persons with atopic eczema are relatively free of symptoms in the summer months. This period of freedom cannot be explained by the deletion of foods from the diet because the diet as a whole is the same, winter and summer. The only difference would be that in the summer we eat extra foods such as fruits and melons, and that wouldn't account for the condition in winter. I can't believe that an allergy would perform in that fashion unless there were some atmospheric explanation, which there does not seem to be. Dr. Howard Osborne of the University of Buffalo is a great believer that dust in homes is the answer to the seasonal occurrence. He suggests that carpeting, wool clothing, and blankets should be scrupulously removed from the person with eczema.

As I said, this is a very controversial subject. Dermatologists as a whole have learned, however, that they can control the condition with topical remedies.

DR. BLUMENTHAL: Thank you, Dr. Ceder. In connection with this subject, there was a very pertinent question asked here: Does infantile eczema tend to develop into asthma when the eczema subsides; also, does the body switch from an eczematous stage to an asthmatic stage; and when one reaction subsides, is the other apt to be reactivated?

Anyone who has been in practice any length of time can't help but be impressed with the fact that a large proportion of these children with childhood eczema develop asthma. When they develop the asthma, their eczema very often disappears. They switch from one to the other. That has been my experience. Would you care to comment, Dr. Henderson?

DR. HENDERSON: I agree.

DR. BLUMENTHAL: Dr. Henderson says that has been his experience; and I think it has been the experience of most men in practice.

Now, there is a question here that I am particularly interested in. It has to do with skin tests. I have written a good deal about it, and I am very much interested in skin tests. I think they are abused a great deal. I think they are extremely useful in many ways because sometimes when nothing else whatsoever will give you a clue, skin testing will. Skin testing is an interpretive process. The question here is, what are the hazards of anaphylactic shock in skin testing? I think these hazards are overestimated. I think it is advisable to do scratch tests first; then if they are negative, to do intradermals. In the aged, where the skin is atrophied and reactions are extremely difficult to read, I have been inclined to use intradermals. In patients with rhinitis, I have been inclined to do intradermals; on patients with asthma, particularly young people, who have a tendency to react very, very strongly, just as they do to anything else, scratch tests are used. After all, you are testing a shock organ. I think in these cases you have to be extremely careful. Shock is rare, of course, but I know that anaphylactic shock can occur. Be sure that you get a good history of allergy before you go ahead with it. When, for instance, a patient says, "Doctor, I am very sensitive to cats," it would be a foolish thing to do skin tests with cat hair.

DR. HENDERSON: I have used intradermal testing with more dilute solutions, such as 1:10,000 solution, which I feel is roughly equivalent to scratch testing. I think if you have only a very small amount, just enough to raise a site—perhaps only 1/200ths of a cc. of material at most—this small amount of such a dilute solution will not cause any trouble. It's foolish to ask for trouble by giving material to which a person is very

definitely sensitive. For instance with cat or other animal danders, in which treatment it's going to be a matter of avoidance anyway, rather than desensitization, skin testing is not necessary. If the physician uses common sense in this regard, and very, very small amounts of material, the likelihood of trouble is very remote.

DR. BLUMENTHAL: We have a question here which I think will interest all of you. Describe the efficacy of poison ivy extracts, both prophylactically and for use after exposure. What is the period of time that it takes to react to poison ivy after exposure? I think this is in the field of Dr. Ceder.

DR. CEDER: Well, Jim Blake made a statement once that the only person who benefits from poison ivy extract is the doctor, because he gets the fee for giving it. As a matter of fact, the efficacy of prophylactic poison ivy extracts, in the past, has generally been regarded by dermatologists as being of very little value. That was based on the old commercial extracts made from the oil suspension of the oleoresins. Most of those extracts were administered in an irregular fashion and usually only a very short time before the season occurred, and the patients as a whole didn't get much protection from them. However, recently in the literature we read about considerable modification of these extracts which is going on. One article is by Dr. Kligman of the University of Pennsylvania. He is evaluating by administering it to a thousand individuals, and he believes that he can produce what is known as hyposensitization. This is not complete protection. In other words, the patch test using the material will still be positive, but from season to season the patients' reactivity is much reduced, but it isn't complete protection. There is another paper in a recent issue of the *Journal of Allergy* on Aqua-Ivy. This is a preparation that is an alum precipitate of the allergen, and is administered at specific intervals over a period of time. It also induces hyposensitization.

Now, again the reaction of the skin, *per se*, will still be about maximum; but there is more systemic response with this. The only real objection is that you cannot achieve a complete desensitization because poison ivy doesn't produce circulating antibodies. That is true of most epidermal irritants, such as ragweed dermatitis

produced by ragweed pollen. But in general we still feel that there is very little value in using the previous commercial extracts as a prophylactic remedy. Therapeutically, I can be a little more dogmatic. We know it's quite hazardous to administer extracts of high potency to a person who is already having a dermatitis from poison ivy. You can get an exacerbation and aggravation of it by the Shwartzman phenomenon; even fatalities have occurred. I have seen severe reactions from it, and it should not be administered at that time. I am quite sure it does very little good. Dr. Howell of Dallas had a group of patients who received extracts of a certain potency; his controls were another group who didn't get any. He compared them, and the course of the disease was the same in both groups.

Now, considering the question of how long it takes for dermatitis to develop after exposure to poison ivy—well, there have been some studies done on that. Generally it occurs within twenty-four or forty-eight hours. It can occur as late as a week after, but the greater percentage will develop lesions within forty-eight to seventy-two hours.

DR. BLUMENTHAL: Thank you, Dr. Ceder. Now we come to one of the most serious problems in allergy, and that is asthma. There has been considerable controversy as to the present status of the treatment of asthmatic patients. The problem of using steroids, or of using the older, more conservative methods of treatment is still being discussed. I think there are very few men in this part of the country who are more qualified to speak on that phase of it than is Dr. Henderson.

DR. HENDERSON: I think we have to divide asthma up into the seasonal type produced by some known precipitating factor, the kind that comes on or gets worse when the hay fever is at its worst, and the perennial type that may be due to combinations of known factors and unknown factors. I think for simplicity we can say most of those cases actually can be classified under asthmatic bronchitis rather than under true allergic asthma. Too many people, both physicians and patients, are using the steroids in both types of cases. The seasonal type of asthma I think we can dispose of fairly simply by saying it is a rather short-term type of thing, due to the

limited season of the offending agent; and the same thing in prevention holds true there, as for hay fever (i.e., avoiding the irritants). In this case we are justified in urging the patients to go to greater lengths to avoid the irritants than we are with hay fever. If he needs to quit work for two or three weeks, have him plan to take his vacation during that time. If he needs to spend enough money to get a room in the home satisfactorily air conditioned, we feel that it is worth while in the case of asthma, even though it may not be the case in hay fever. It is just a matter of what the patient will put up with in the way of a nuisance. In the case of asthma we need to impress on the patient the future course of the disease and that eventual disability may result from complications of asthma, particularly emphysema. In any case of asthma we should proceed with a view to a long term treatment; start out with the assumption that it's a difficult disease to manage and we are going to have to go "all out" to take care of it.

In the asthmatic bronchitis cases we are going to be confronted with the situation where the patient is in distress, has symptoms of cough and wheezing, often sitting up at night to get his breath, and requiring a doctor's visit. This many times builds up a great fear in the patient that perhaps he cannot reach the doctor in time to get help, so we have a large psychogenic factor in a great many of these cases of asthmatic bronchitis. Then the patient hears of some friend who has had some of the steroids, and is getting along fine and having no trouble at all. "Why can't I have that instead of fiddling along with this suppository and this shot?" he asks. In the first place, you have to sit down and have a talk with these people and outline their status as far as the future, long-term care of the condition is concerned. Usually at the same time you talk to them about the hazards of the steroids. I am very frank with these people and perhaps at times overemphasize the statistics in order to make them fully aware that they can't take steroids like aspirins or the antihistamines; they are more of a last resort type of treatment rather than the first type to use. After that is understood and we have checked on any skin tests that might be indicated for specific factors, then we start talking about eliminating respiratory irritants in general. In a lot of these cases where skin tests are unhandy to do, you can get by perfectly well without them,

particularly in older people. You may have some pretty good ideas as to whether dusts, temperature changes, dampness, drafts, or anything similar are particularly bothering him. You can get some idea as to whether a pet is causing the trouble. In general, whether the skin test is negative or positive in this group of people, I tell them they ought to have a bedroom as lint-free and dust-free as possible; to sleep in a warm bedroom that is draft-free, and to get rid of the feather pillow, not particularly because they are feather-sensitive but because the pillows are another source of dust and mold. It is good to have the bedroom floor bare or with linoleum or linoleum tile, or washable rugs. Get rid of venetian blinds and drapes, and have no pets with hair or feathers in the house. This means that dogs, cats, parrots, parakeets, and that type of thing should be eliminated. If the patient is a farmer, we talk about how he can eliminate some of his contacts, and maybe some jobs that he has been doing that he can avoid; perhaps he has help to whom he can delegate some of the jobs that are particularly dusty or dirty. An oronasal mask is something not to be overlooked. A lot of times a farmer who has to be in the barn throwing down some feed, milking cows, or something like that, can avoid a good deal of this contact if he wears one of these masks made out of plastic or rubber with an adequate filter disk of some kind. They usually run to \$3.00 to \$5.00, and are available at most pharmacies. A farmer can do a good deal of work using one of these, but there is a certain respiratory lag which makes them rather undesirable for certain work. So we proceed on the avoidance of irritants of all types as much as possible.

Then the second thing is to talk to them about symptomatic treatment. Many of them have taken medicine that made the heart speed up; they felt that they would be better off simply to sit up until the wheezing subsided, thereby getting back to a rather uneasy sleep without taking any medicine. I reassure them that most of the medicine used for asthma that causes the speeding up of the heart does no more harm to the heart than when they walk upstairs, and that it's a physiologic symptom. If they are having enough trouble to warrant taking some medicine, they should take it by all means.

I try to outline for them the classifications of medicines—the quick-acting ones, the shots and

inhalants; and the slow, more prolonged-acting ones, such as the ephedrine compounds, which, combined, complement each other.

The third type of symptomatic treatment is the iodide preparations. I don't think they ought to be sold short at all. Many times a patient has been taking a good deal of the ephedrine compounds but is troubled with a cough, and dry, sticky mucus. Our average dose of potassium iodide is ten drops of saturate solution three times daily in a glass of water. I warn them of the possibility of a rash, and instruct them to drop the dosage if a rash occurs. Often they can tolerate a smaller dose of a size that will still be helpful. Also aminophyllin suppositories can be given for nighttime use in patients who have a lot of nocturnal trouble.

So we go through the whole program of avoidance and symptomatic treatment. Then the third thing is to consider desensitization, if there are some specific irritants that we have reduced to a minimum but with which the patient is still having some contact, I think we can assume that in most chronic asthmatic bronchitis, desensitization will not be as helpful as in the seasonal type of asthma. There is a large mechanical factor to consider. In some of these patients, even though we found house dust sensitivity by

skin tests and have desensitized the patient to the chemical substance in house dust, there is a good deal of mechanical irritation on contact with it and they can get symptoms even though they are desensitized. For that reason I am not so anxious to start a desensitization program in chronic asthmatic bronchitis, even with positive skin tests, as I am in the seasonal type of case.

Now, we come to the steroids and they are the last thing; I say the last because that is where I think they belong. If we have a patient with asthma severe enough to warrant hospitalization despite having followed a good conservative program, then I think that it's time to treat him with the steroids. We start them with some intravenous preparation, and then follow with oral medication for a few days. We try to stop the preparation after four, five or six days of treatment. Many of those who come to us have already been on the steroids and have run into trouble because they haven't paid adequate attention to the more conventional measures, and have gotten into trouble despite the steroids. In these people you have to go ahead with the steroids, at least for a while, until you can swing back into the other measures. The aim with steroids is always to treat the patients as short a time as possible, then to discontinue steroid therapy.

MODERN INSECTICIDES CAN BE MENACE TO HEALTH

A bulletin from the Minnesota State Medical Association warns that accidental poisonings from the misuse of modern insecticides are alarmingly frequent. It is vital that the public become aware of their potential dangers and learn how to use the compounds properly. Many of the more highly poisonous organic insecticides are restricted to agricultural uses. Individuals working with these compounds know that it is essential they wear protective clothing and goggles when they are engaged in their work, for poisons like Parathion, TEPP and HETP can be absorbed through the skin, respiratory tract and eyes as well as the gastrointestinal tract.

Insecticides may be used safely by following these ten simple rules:

1. Read the label carefully; follow instructions and observe the caution statements.
2. During use, avoid inhaling sprays or dusts and be careful not to spill any on your skin. If you do, wash immediately with soap and water. If your clothing becomes contaminated, remove it and wash it before you wear it again.
3. When dusting and spraying fruits and vegetables

in your garden, do not allow insecticides to come in contact with the edible portion of the plant.

4. Indoors, avoid food contamination by covering all food, food utensils and food preparation areas while spraying.

5. Do not spray children's toys, cribs or clothing.

6. Do not spray rooms occupied by infants or sick people.

7. Never store unused insecticides in empty food or beverage containers, food cupboards, medicine cabinets or other places where there is danger of food contamination or mistaken use. A high shelf or locked cupboard is a good place for storage.

8. Always keep insecticides and insecticide poisoned bait out of the reach of children and pets, even during the times you are using them.

9. Dispose of empty containers immediately where children and pets cannot get to them.

10. Do not use insecticide vaporizers or fumigators in your home.

Pharmacology for the Family Physician

R. N. BIETER, M.D.
Minneapolis, Minnesota

ONE OF the most interesting groups of new drugs in recent years is the ataractic, or tranquilizing, drugs. These drugs have come into great usage in recent years. They have actions something like the hypnotics, and in some respects something like the opium analgesics. In other words, all of these drugs act chiefly upon the central nervous system. Since they have similar actions, a description of the ataractics and a comparison of them with some of the effects of the hypnotics, particularly the barbitals and the opium analgesics might be interesting.

The ataractics as we know them today are made up of the following: Reserpine, an alkaloid from a crude plant which comes from India, which is used in various doses; the French introduction, chlorpromazine or Thorazine, which is used in doses beginning at 60 to 100 milligrams; meprobamate (Miltown or Equanil), which is used in beginning doses of 100 to 200 milligrams; azacyclonal, or Frenquel, the dosage of which begins with 15 or 30 milligrams; and promazine or sparine, the dosage of which, like chlorpromazine, begins at about 100 milligrams. There are two or three other drugs in the process of being introduced and which are experimental. The principal pharmacologic property of these drugs is to block the reactions and the behavior produced by exaggerated emotions. These emotions are tension, excitement, anxiety, fear, anger, worry, and probably some forms of emotional pleasure. These emotions, especially anxiety and fear, as you know, can produce rather marked disturbances and even pathologic behavior. At times, this leads to the patient's being emotionally disturbed and the final result is hospitalization.

An experimental example of the type of effect produced can be seen if one of these drugs is given to a monkey. You all know monkeys well enough to know that if you go up to a cage containing a monkey, it quickly becomes excited. If one reaches into the cage to pick up the monkey, it will bite and claw. If the monkey is first

given a drug, such as chlorpromazine, and then it is picked up, it is almost as gentle as a cat. This is the type of action we have never seen before in pharmacology.

How is it produced? We don't know the whole story, but it appears these drugs act upon the hypothalamus or associated subcortical structures. In other words, their effect is entirely at the base of the brain. It is known that in the region of the hypothalamus there are areas where one can apply an electrical current which produces what appears to be strong emotions in an animal. One can cut regions out of the hypothalamus, and one gets the direct opposite effect, placidity and lack of emotions. That is the evidence supporting this theory of action. These drugs appear to depress the hypothalamic region. We don't know if it is the hypothalamus or associated structures, but I will call it the hypothalamic region for lack of a better term. In addition, they reduce the effect of the hypothalamic region on the higher centers of the cerebrum. Impulses arise and produce strong emotions in the hypothalamus; other impulses are then sent up into the cerebrum to produce excitement and the other phenomena of emotion.

Now, the significant thing is that the highest mental processes—as for example, judgment, attention, learning, and perception of sensation—are affected little or not at all. In other words, mental activity after taking an ataractic drug is more or less normal. If the exaggerated emotions produce insomnia, these drugs will produce sleep; but if a really severe insomnia is present from other causes, the ataractic drugs probably will not produce sleep.

I want to go back for a minute and discuss the experimental technique for studying these drugs. One of these was introduced by Joseph Brady of the Walter Reed Army Hospital in Washington. It has to do with behavioral tests which came out of psychologic research. The experiments are carried out on both rats and monkeys. The animals, after being deprived of food or liquids for

Presented at the Minnesota Academy of General Practice, Saint Paul, Minnesota, October 17, 1957.

twenty-four hours, are placed in a container where they learn to press a bar to obtain small amounts of food, or a drop of liquid, such as orange juice. With practice, the animals will learn that they will only get food or water by pressing this bar. After a time, they will do this so routinely that one gets a perfectly straight curve of their food or water intake. After the animals have learned this, another stimulus is added. This is a clicking noise which lasts for three minutes and terminates in an electrical shock administered to the feet of the animal. The animal soon learns to recognize the auditory stimulus terminating in a shock by showing a fear or anxiety reaction. This reaction consists of crouching, with or without defecation, and a marked reduction in bar pressing. During this anxiety reaction, the animals just stop pressing the bar. The three minute anxiety-producing stimulus is given at seven-minute intervals. Drugs can affect this experiment as follows: Amphetamine, which, as you know, is a cerebral stimulus, leads to a 100 per cent increase in bar pressing during the seven-minute or so-called control period; whereas during the three-minute anxiety period, bar pressing is reduced completely to zero. On the other hand, with reserpine, bar pressing is reduced 50 per cent during the seven-minute control or anxiety-free period whereas during the three-minute anxiety-producing period, the animals go ahead and press the bar normally. In other words, inhibition to bar pressing is removed with reserpine. This drug either obliterates anxiety or prevents the reaction from it. During the anxiety-producing period, the animals go ahead, press the bar, and eat or drink normally.

A similar type of experiment has been conducted by Heistad at Minnesota, using chlorpromazine in rats treated in a similar manner. Rats given two and a half milligrams of chlorpromazine per kilo—that is a reasonably good-sized dose for a human being—showed a reduction of the anxiety or fear reaction, but not so great or complete as Brady got with reserpine. Those are the only two experiments that I know that give you this comparison. I believe the results are comparable.

In addition to this effect in the hypothalamic region, the blocking of anxiety, fear, et cetera, there are some other effects produced by these drugs. This occurs because, in the hypothalamic region, there are other nuclei controlling or pro-

ducing a lot of other effects in our bodies. All these nuclei are so close together that it is very difficult to separate one from the other. Here are some of the things that happen: The hypothalamic region controls our homostatic mechanism—circulation, respiration, digestion; and close by is the hormone master gland, the pituitary. That means the hormones also play a role in controlling these activities. Stimulation studies have shown that circulation, respiration, digestion can be affected from this region. These drugs, as you know, lower blood pressure. This is rather a common reaction. This effect is probably central, due to a depression in the hypothalamic region. Reserpine can increase motor activity in the gastrointestinal tract and increase the hydrochloric acid secretion. This at times is a dangerous effect. On the other hand, chlorpromazine does the reverse. It depresses the gastrointestinal tract and probably reduces the hydrochloric acid secretion. All of these drugs can lower body temperatures. If large enough doses are given, the temperature will become subnormal. There is an emetic center in this region, and these drugs are the most markedly antiemetic substances known in animals. In addition, there are fiber tracts going through the area which are extremely important in correlating the subcortical parts of the brain with the cortex. One of the fiber tracts is the reticular activating system. This system, when it is stimulated, produces a marked awakesness or alertness. You all know that under excitement an individual becomes wide awake. This is undoubtedly due to the reticular activating system sending stimuli up to the cerebrum. This system is depressed by at least one of those drugs, but not markedly so, and that is chlorpromazine. A depression of the reticular activating system should lead to quiet and tranquillity. You notice I am using the terms quiet and tranquillity in referring to the ataractic drugs, and I am keeping hypnosis and sedation as terms for the barbitol action.

There is another area in the hypothalamic region called the amygdala. We have known for a long time that when the amygdala shows electrical activity, it sends impulses into the hypothalamus and quiets it. In other words, increased activity of the amygdala will make the hypothalamic nuclei more quiet. It's been shown that chlorpromazine increases the activity of the amygdala. In other words, if this is the principal mechanism of action,

and it looks as if that may be the case, here is a drug that increases the activity of one part of the central nervous system to depress other parts of the central nervous system.

Furthermore, in the cat, chlorpromazine, given in larger doses, produced a marked increase in the electrical excitability of the entire brain stem and the entire cerebral cortex, leading to grand mal seizure. That has been seen clinically—and likewise convulsions have been seen under chlorpromazine. It looks as though at a certain dosage level one can markedly increase the passage of impulses through the entire nervous system.

Meprobamate or Miltown has quite the opposite effect. When given in large doses to animals, it produces a very remarkable flaccid paralysis that is reversible—complete relaxation of muscles. Meprobamate is also antagonistic to strychnine convulsions. It is possible that in a patient on this drug, in addition to the ataractic effect, relaxation of muscles may also be an advantage.

Briefly, these are the important effects of the ataractic drugs. As you can see, they are rather striking, and a little bit different from anything else we have ever had before. Now let's briefly consider the barbitol hypnotics and point out some differences and similarities.

The barbitol hypnotics, as we have known for a long time, produce a uniform depressant action on the entire central nervous system. During this effect the electroencephalogram shows a typical picture of sleep. The direct opposite is true from the ataractic drugs. The action of barbitol, as you know, leads to hypnosis and sleep, and ultimately with suitable doses to general anesthesia. This cannot be done with the ataractics. In the action produced by the barbitol hypnotics, it is important to remember that the highest mental activities are depressed: Auditory reaction time is reduced, memory is dull, and motor responses all go down below normal, just as is the case with alcohol. This is a striking difference to the ataractics. Emotions probably are also depressed by the barbitals. Large doses show that the barbitals relax muscles. The overall action of barbitals can now be summarized by saying the action is similar to a decerebration. There occurs also a slight drop in blood pressure, slowing of respiration, and an anti-emetic action.

The action of morphine is much like that of the barbitals plus an extensive depression of the pain centers. Probably this is chiefly cortical. One

gets the same hypnosis, the same tendency to sleep, plus a striking elimination of the sensation of pain. The highest mental processes again are markedly depressed and the hypnosis is marked. There is undoubtedly also a marked effect of morphine on the emotions—a loss of emotions which leads to a striking picture of indifference.

Many people studying pain have noted that human beings given morphine will not complain of pain. If one asks them about it, they will say, "I feel it, but I don't give a damn about it." In other words, this is similar to the reaction one gets with the ataractics. Morphine also will stimulate the vomiting center, it may depress respiration, and it will lower blood pressure very slightly. You can see there are similar points of action in the three groups of drugs, all of which act on the central nervous system.

If this is the case, what happens if one gives some of these drugs together? We don't know the whole answer, but here are some suggestions. It's been reported that the ataractics plus morphine give better pain relief. As far as pain itself is concerned, that probably is not true. The best workers have found that the control of pain produced by morphine is just as good as when an ataractic drug is added; but that the ataractic drug may increase the control of emotions and produce more indifference. There are times in the history of a human patient where you have a tremendous emotional disturbance where an ataractic plus morphine or any other analgesic may be superior to the use of morphine alone.

The sleeping time in animals produced by the hypnotics, more particularly the short actors, is definitely prolonged in the ataractic drugs. In fact, this is one of the experimental tests of an ataractic drug. Whether it is a good test or not, we do not know.

This prolongation of the sleeping type of hypnotics may be due to the depression of the activating system by the ataractic drugs. The general anesthetics are also potentiated with the ataractic drugs, and so is alcohol. However, there is the possibility that these drugs may over depress the hypothalamic center and lead to over deep anesthesia, which may be dangerous.

These drugs came into use in psychiatry chiefly, where they were used to control excitement, delirium, tension, agitation, anxiety, worry, fear and depression. Yet today these drugs are being used

more outside psychiatry than inside it. The symptoms I have mentioned, such as excitement and anxiety, are not of extreme danger, for every normal individual at some time experiences one or more of them. Most normal individuals learn in the process of growing up how to use these emotions for improving their education, improving their living conditions, improving their association with other individuals. So it can be said these emotions do serve a useful purpose. How many of us would have graduated from medical school if we had not experienced anxiety. In other words, anxiety and worry are things to help us to grow up and are absolutely essential in our lives. So we can't say we should eliminate them from life entirely. At times the stimulus leading to one or more of these emotions may be extremely intense and prolonged—for example, during a catastrophe or during a limited illness, such as delirium tremens. In some of these instances, a physician is justified in using one of these drugs. On the other hand, in certain diseases such as schizophrenia, where these symptoms become extremely marked and lead to such an alteration in behavior that the individual has to be hospitalized and cannot take care of himself or herself, these drugs have produced rather remarkable results. The barbitol hypnotics will also relieve emotions. A schizophrenic patient can be given a barbitol, leading to control of the emotions. He will then become quiet, but, in addition to this, he becomes sleepy, and will show disturbed or dulled sensations and various degrees of motor incoordination. This person cannot take care of himself or herself. On the other hand, the ataractic drugs act by blocking or inhibiting some of the relay centers in the pathway associated with abnormal behavior only, thus leaving the cerebral areas necessary for our highest mental processes in a comparatively normal condition. This will result in an individual who can be up and around, who is reasonably alert mentally; and who can take care of himself and get along with other people in his surroundings. This is a step forward in the treatment of these patients.

It should be emphasized that these drugs produce only symptomatic relief. There is no evidence that they are curative. Unfortunately, the use of these drugs has brought with it a number of side effects. Chlorpromazine may cause extrapyramidal disturbances like Parkinsonism. Sometimes only

after a disturbance of this type will the drug show ataractic action. This disturbance suggests increased transmission of motor nerve impulses; which can be controlled with a drug like Artane. Chlorpromazine may produce convulsions or jaundice. When this occurs, the drug should be discontinued. One school of thought believes this is due to an obstruction in the biliary passages and suggest the administration of the drug should be continued. A symposium in New York City last June was strongly in favor of this viewpoint. Another school of thought believes that the jaundice is an allergic manifestation and the drug should be discontinued.

Both reserpine and chlorpromazine have been known to produce a depressive psychotic reaction. This is important. Two hundred such instances have been reported from reserpine as of last June. This suggests these drugs will change the emotional status of human beings, but not always in the direction of normalcy. For this reason reserpine probably shouldn't be used in the depressive stages. Because reserpine increases gastric secretions, it should not be used in a gastric disturbance.

For this reason, the Food and Drug Administration recently suggested reserpine be used cautiously. They found in studying the use of reserpine in the United States that a dose of .32 milligrams per day raises gastric secretion and gastric acidity in a significant number of cases. A dose of half a milligram per day in two weeks raises gastric acidity in most patients. An occasional massive gastrointestinal hemorrhage and ulcer perforation have been reported at half a milligram of reserpine per day. A half to one milligram a day produces severe depression and has resulted in a number of suicidal attempts among human patients. A dose of three-quarters of a milligram and up should be given to patients only in a hospital. The only dose safe to give a human patient as far as we know today without producing any of these disturbances is a quarter of a milligram per twenty-four hours.

The barbitals are habit forming; morphine and its synthetic derivatives also are habit forming. The pharmacologist failed to find these actions in the laboratory until after physicians found such effects in human beings. It may be the same way with the ataractic drugs. There is evidence that

Pulmonary Fibrosis

BARRY DECKER, M.D.
R. DREW MILLER, M.D.
Rochester, Minnesota

PULMONARY fibrosis is an anatomic descriptive term that earned wide acceptance as a diagnosis for poorly understood respiratory illnesses casting persistent diffuse shadows on the roentgenogram during life and revealing scar tissue in the lungs at necropsy. As understanding of pulmonary disease matures, the obligations of the clinician become more exacting; thus, he no longer is permitted the luxury of this generalization but must qualify the categorical term "pulmonary fibrosis" as related to some known cause or by pathologic and physiologic description, such as pulmonary fibrosis secondary to Boeck's sarcoid, pulmonary fibrosis following streptococcal pneumonia, pulmonary fibrosis of berylliosis, or diffuse interstitial pulmonary fibrosis of Hamman and Rich.

Pathologists have known for a long time that minor degrees of pulmonary fibrosis are commonly seen at necropsy. The clinician is concerned only with those types of fibrosis which are manifest during life. Definitively, therefore, pulmonary fibrosis includes respiratory diseases associated with formation of fibrous tissue in the lungs of sufficient degree to be characterized clinically by abnormal roentgenographic shadows or functional impairment of respiration or both.

Pulmonary fibrosis should be distinguished from diffuse pulmonary disease. Inflammation, congestion and some types of neoplasms also cast shadows on the thoracic roentgenogram indistinguishable from those of fibrosis. The etiologic factors and the physiologic alterations of reversible inflammatory lesions may be identical with those of fibrotic lesions. The most reliable clinical evidence of pulmonary fibrosis is the persistence of roentgenologic shadows or of symp-

toms of respiratory insufficiency. The diagnosis, however, remains a clinical presumption until it is confirmed by histologic examination.

As recently as 1939, an etiologic classification of pulmonary fibrosis included only tuberculosis, silicosis, bronchopneumonia, chronic bronchitis, pleurisy and rare causes, such as syphilis and alcohol.¹ Rapid increase in clinical knowledge concerning this problem resulted in the more detailed etiologic classification of diffuse pulmonary lesions reported by King, in 1949.² This classification encompasses a wide variety of entities associated with or resembling pulmonary fibrosis as seen roentgenologically (Table I).

Normal Function of the Lungs

The primary function of the lungs is the exchange of oxygen and carbon dioxide between the body and the atmosphere. Actions concerned with acid-base balance, regulation of heat, water balance and reticuloendothelial processes are secondary. The aerobic cellular metabolism of the body requires replenishment of oxygen and excretion of carbon dioxide. Exchange of gases between the tissues and the circulating blood permits the metabolic demands of cellular oxidation to be made on the distant lungs.

The alveolus is the functioning unit of external gaseous exchange. The pulmonary parenchyma forms a framework through which courses a rich capillary network. The external exchange of gases occurs as a result of three closely integrated functions, namely ventilation, circulation and diffusion.

Ventilation.—The alveoli are connected to the exterior by the tracheobronchial tree. An alternating flow of air is produced by rhythmic alterations in intrapulmonary pressure, with respect to atmospheric pressure, induced by the repetitive action of respiratory muscles on the thoracic cage. This movement of pulmonary gases is pulmonary ventilation, and it has been referred to as the

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

“bellows action of the lung.” The bellows action depends on the normal function of the muscular and nervous systems. The work required in ventilation is influenced by the viscoelastic properties

Effects of Pulmonary Fibrosis

Each major respiratory function, namely ventilation, perfusion and diffusion, may be affected by pulmonary fibrosis, depending on the location

TABLE I. AN ETIOLOGIC CLASSIFICATION OF DIFFUSE PULMONARY FIBROSIS
(FROM KING)²

Infections
Tuberculosis
Bacterial—streptococcal, micrococcal, brucellosis, tularemia
Mycotic—moniliasis, aspergillosis, coccidioidomycosis, actinomycosis, blastomycosis, histoplasmosis, torulosis
Rickettsial—Q fever
Viral—psittacosis, varicella
Parasitic—schistosomiasis
Inhalations
Industrial—silicosis, asbestosis, berylliosis, siderosis, bagassosis, byssinosis, vanadium, silver, talc, aluminum, barium
Other inhalations—vomitus, lipiodol, kerosene
Thermal injury
Neoplastic
Primary tumors—bronchogenic carcinoma, alveolar carcinoma, pulmonary adenomatosis
Metastatic tumors—stomach, liver, prostate, melanotic sarcoma, hypernephroma, tongue, thyroid, breast, pancreas, ovary, uterus
Generalized tumors—lymphoma, reticulum cell sarcoma, multiple myeloma
Blood dyscrasias—myelogenous leukemia, polycythemia vera, sickle cell anemia
Generalized systemic diseases—sarcoidosis, erythema nodosum, rheumatic fever, lupus erythematosus, periarteritis nodosa, Löffler's syndrome, tropical eosinophilia, cystic disease of the pancreas, xanthomatosis, amyloidosis, scleroderma, calcinosis
Fibrotic conditions—fibrosis, granulomatosis, bronchiolectasis, acute interstitial fibrosis, bronchiolitis fibrosa obliterans
Circulatory diseases
Pulmonary edema—without cardiac disease
Cardiac disease—pulmonary edema, hemosiderosis in mitral stenosis
Renal disease—pulmonary edema, hemorrhagic edema
Emboli and infarcts—phlebitis, lipiodol, fat

of the lungs. Normal ventilation requires relatively homogeneous distribution of atmospheric air to the various alveoli.

Circulation.—Circulation of blood to the alveolar capillary network is known as “perfusion.” The normal functions of the right ventricle and atrium, and the pulmonary vascular tree, as well as the great systemic veins returning blood to the right side of the heart, are integral parts of the pulmonary circulation. Normally, a relatively balanced relationship exists between ventilation and perfusion in the alveoli of various parts of the lungs.

Diffusion.—The passage of gases across the alveolocapillary barrier, or diffusion, is the third major aspect of pulmonary function and is dependent on normal ventilation and circulation. Changes in thickness or in the physicochemical nature of the alveolocapillary membrane or a reduction in its total surface area may result in impaired diffusion and hypoxia.

and nature of the pathologic changes. Extrapulmonary fibrosis decreases the elasticity of the thoracic wall, thus increasing the load placed on the pulmonary bellows and increasing the work of ventilation. Similarly, fibrosis may occur in or about major airways, decreasing their luminal diameter. The resulting increase in frictional resistance to the flow of air increases the ventilatory work load on the muscles of respiration.

The distribution of gases within the lungs may be altered by bronchiolar fibrotic obstruction. Ball-valve mechanisms in the smaller airways produce distention, rupture and coalescence of the distal alveoli, resulting in a loss of alveolar elasticity and a decrease in the alveolocapillary diffusing surface.

Perfusion of any given region of the lungs may be decreased by focal fibrosis of the pulmonary vascular network. When perivascular fibrosis is sufficiently diffuse, pulmonary hypertension develops to maintain the necessary flow of blood. Fibrosis of the alveolar or capillary walls, often referred to as “interstitial fibrosis,” may result in a

diffusion barrier despite relatively normal ventilation and circulation.

Appreciable degrees of pulmonary fibrosis may occur without symptoms of pulmonary insuffi-

The various aspects of pulmonary function are rarely affected individually. While ventilation is greatly impaired in emphysema, loss of diffusion surface also occurs. Pulmonary endarteriolitis

TABLE II. AN ANATOMIC-PHYSIOLOGIC-ETIOLOGIC CLASSIFICATION OF PULMONARY FIBROSIS

- I. *Anatomic: Parenchymal*
Physiologic: Reduced pulmonary volumes; may be asymptomatic unless extensive
Etiologic:
 - Postinfectious (primary and secondary to local bronchial obstruction)
 - Pyogens—streptococci, micrococci, pneumococci
 - Tuberculosis
 - Fungous infections
 - Inhalants (pneumoconioses)
 - Silicosis
 - Baritosis
 - Siderosis
 - Sarcoidosis
 - Infestations—amebiasis
- II. *Anatomic: Tracheobronchial*
Physiologic: Altered pulmonary volumes; impaired ventilation (rate and distribution)
Etiologic:
 - Postbronchitis—bronchiolitis (same causes as postinfectious above)
 - Asthmatoid (nonspecific—multiple aggravating factors)
 - Bronchiectasis—postinfectious
 - Chronic fibrocystic disease (pancreas, liver)
 - Kartagener's syndrome
 - Pneumoconioses
 - Byssinosis
 - Bagassosis
 - Thermal injury
- III. *Anatomic: Interstitial (alveolar wall)*
Physiology: Reduced pulmonary volumes; hypoxia; hyperventilation
Etiologic:
 - Postinfectious
 - Viral—exanthems, primary atypical pneumonia
 - Rickettsial—scrub typhus, Q fever
 - Chemical
 - Beryllium
 - Hexamethonium (rare)
 - Apresoline (rare)
 - Radiation
 - Collagen diseases
 - Scleroderma
 - Dermatomyositis
 - Lipoidoses—(Hand-Schüller-Christian disease)
 - Tuberous sclerosis
 - Hamman-Rich syndrome
 - Congenital alveolar dysplasia
- IV. *Anatomic: Vascular*
Physiologic: Altered perfusion; pulmonary hypertension
Etiologic:
 - Infarction
 - Emboli
 - Thrombi
 - Vasculitis and perivasculitis
 - Collagenous—periarteritis nodosa, lupus erythematosus
 - "Lymphogenous" spread of carcinoma
 - Hemosiderosis
 - Microscopic emboli without infarction
 - Schistosomiasis
 - Allantoic (post partum)
 - Fat particles

ciency. Regardless of origin, when fibrosis remains focal and leaves intervening zones of normal lung, over-all pulmonary function may be only minimally disturbed, depending on the remaining pulmonary reserve.

primarily produces vascular obstruction, but diffusion also may be decreased by the thickening of the alveolocapillary barrier. Considerable difficulty in anatomicophysiologic correlation also results from the multiple potential localizations of

many individual pulmonary diseases. Thus, classic Boeck's sarcoid produces extensive parenchymal nodular disease, often with minimal physiologic impairment; however, involvement of bronchial walls may occur, disturbing ventilation and producing disabling emphysema. Similarly, in some cases of Boeck's sarcoid, diffuse granulomatosis of the alveolar walls results in alveolocapillary block.

Correlative Classification

Since many of the etiologic agents that cause pulmonary fibrosis may lead to varied anatomic and physiologic abnormalities, a classification correlating etiology, pathology and physiology is fraught with duplication. Nevertheless, the clinical picture in any case is an integration of these factors. Thus, a correlative classification appears warranted as the basis of a systematic clinical approach to pulmonary fibrosis.

The works of two authors are notable. Spain³ classified pulmonary fibrosis anatomically as bronchial, interstitial, parenchymal, vascular and pleural. Describing the physiologic abnormalities of pulmonary fibrosis, Wright and Filley⁴ considered parenchymal, peribronchial and interstitial lesions. Borrowing generously from these authors, we shall consider parenchymal, tracheo-bronchial, interstitial and vascular pulmonary fibrosis, as well as the resultant abnormal physiology and the more common causes of each (Table II).

Parenchymal Fibrosis

Parenchymal fibrotic pulmonary lesions, whether single or multiple, regional or multifocal, involve portions of the pulmonary parenchyma but leave intervening zones of normal lung. All the healed necrotizing pneumonias are to be considered in this category. Also, those granulomas or diseases with formation of nodules that encroach on the surrounding parenchyma produce a similar distribution of pathologic changes.

Roentgenologic study reveals these lesions as isolated regional disease, such as the fibrosis secondary to healed bacterial or tuberculous pneumonia or the more diffuse nodular pattern of Boeck's sarcoid or nodular silicosis. The parenchymal lesions may manifest little or no physiologic impairment. Between the diseased portions are zones of relatively normal lung, and the vascular perfusion of the diseased tissue is minimal.⁴ The anatomic basis for the shunting of blood away

from these fibrotic regions is varied and includes such changes as fibrotic or thrombotic occlusion of the vessels in the involved zones or the vasoconstricting effect of hypoxia in the locally involved and underventilated portions of the lungs. Thus, both ventilation and perfusion may be reduced or absent in the involved parts. The functional result is similar to that of pulmonary resection. It is well known that patients who have had multiple lobectomies or pneumonectomy may carry on well if the remaining parenchyma is normal.

Results of Pulmonary Function Tests.—The pulmonary volumes,⁵ including vital capacity, inspiratory capacity, functional residual capacity⁶ and total capacity, usually are decreased to a similar degree, leaving the ratio of residual volume to total capacity less than 35 per cent. The maximal breathing capacity, as a measure of maximal ventilatory effort, may remain at or near normal. The percentage of nitrogen in the lungs after the patient breathes pure oxygen for seven minutes is less than 2.5 per cent, indicating normal distribution of gases in the lungs. Arterial hypoxia is absent.

Occasionally, in the more generalized and yet focal fibrosis, with most of the pulmonary parenchyma remaining normal, the only abnormality found on testing pulmonary function may be resting hyperventilation. Since this occurs in the absence of ventilatory failure and arterial hypoxia, it has been attributed to fibrotic constriction around the sensory receptors of the Hering-Breuer reflex. As a result of hyperventilation, mild respiratory alkalosis occurs, with increase in the blood pH and decrease of the blood carbon dioxide tension and carbon dioxide-combining power.

When disease involves a region of one lung, the over-all function may be essentially normal yet bronchspirometric examination may show a wide difference in the performance between the two lungs. Normally, the right lung, being somewhat larger, accounts for about 55 per cent of the total pulmonary function.

Etiology.—Many etiologic entities may produce local, regional or diffuse focal disease with little resulting disability. The destruction of pulmonary tissue in tuberculosis is well known. In recent years, the similar potential of numerous fungi has been stressed. Similarly, the necrosis associated with Friedländer's, streptococcal or micrococcal pneumonia is familiar. Nonnecrotizing pneu-

monia, primarily pneumococcal, ordinarily heals without fibrosis. With altered intrinsic factors present, however, intra-alveolar and intrabronchiolar fibrosis may ensue. Gleichman and associates⁷ noted that twenty-two of fifty-two patients who had fibrosis associated with unresolved pneumonia gave evidence of decreased bronchial drainage caused by upper respiratory, peribronchial or endobronchial obstruction, or by impaired ciliary action secondary to malignant tumors, inflammation, foreign-body reaction, asthma, bronchitis or bronchiectasis. The nature of the intrinsic tubular disease determines the distribution of the resultant fibrosis. The diffuse bronchiolar obstruction of asthma is accompanied by diffuse bronchiolar fibrosis distal to the obstruction. Primary bronchogenic carcinoma may be accompanied by regional fibrosis of the occluded segment. Tularemia and plague, while primarily glandular infections, have a pneumonic phase with necrotizing pneumonia, giving a high mortality rate. With recovery, parenchymal fibrosis ensues. Amebic infestation of the lungs, although rare in this country, may be associated with parenchymal destruction. The lungs may be involved by way of the blood stream or by transdiaphragmatic extension from the liver.

Massive necrosis and fibrosis may result from localized exposure to large doses of radiant energy, either x-rays or radioactive isotopes.

Boeck's sarcoid is a nonnecrotizing granulomatous disease resembling tuberculosis that affects the entire body, with a predilection for lymphoid tissue. The lungs show hilar adenopathy, fibrosis and nodular granulomas originating in the perivascular and perilymphatic tissue or alveolar walls and encroaching on the surrounding parenchyma. While the lesion is not in itself fibrotic, it heals by scarring, the extent of which is proportional to the previous granulomatosis. Clinically and roentgenographically, sarcoidosis may exhibit surprising remissions and exacerbations. Reisner⁸ studied thirty-three cases of pulmonary sarcoid; the lesions regressed in a third, remained stationary in a third and progressed in a third.

Interstitial nodules may be found in some of the various types of pneumoconiosis. In any reaction to dust, the inhaled particle reaches the alveolus or bronchiole, where it is ingested by wandering phagocytes. Contained within the phagocyte, the particle traverses the lymphatic system centrally, finally reaching the hilar nodes.

The increase in dust-laden and pigment-laden phagocytes within the lymphatic system may give rise to roentgenographic abnormalities suggesting hilar adenopathy and increased bronchovascular markings that do not, however, imply fibrosis. Two types of pneumoconiosis, without fibrotic potential and in which focal collections of dust-laden cells within the lymphatic system produce pseudonodulation, may resemble silicosis. These are siderosis⁹ among arc welders and baritosis¹⁰ among barite miners or processors. Fibrosis and disability are absent in both conditions despite considerable roentgenographic changes.

In silicosis, after the dust has been distributed within the lymph nodes and interstitium, the phagocytes are destroyed, leaving necrotic foci with surrounding fibrosis that ultimately shrink to dense whorled collagenous nodules. This process occurs within the lymph nodes and in the peribronchial interstitium at the site of branching pulmonary vessels. Nodules may occur within the walls of the bronchi and consequently distort and obstruct them, leading to secondary obstructive emphysema. These nodules gradually may coalesce by means of atelectasis, juxtaposition or, more importantly, pyogenic or tuberculous infection to which the tissues are sensitized. Central cavitation owing to tuberculosis or ischemic necrosis may occur. In the syndrome of rapidly developing silicosis, thought to be related to overwhelming exposure, silica is not transported centrally to the lymph nodes but is deposited in the bronchial walls and peribronchiolar interstitium, resulting in diffuse interstitial fibrosis. The clinical picture of silicosis may be complicated by the admixture of other dusts that by themselves are not fibrogenic. Whereas anthracosilicosis or siderosilicosis may be associated with bronchopulmonary symptoms, it is usually the content of silica that induces fibrosis.

Asbestosis is a more diffuse process, with less nodulation. The fibrotic reaction is more typically bronchial and peribronchial, and its diffuseness may result in severe disability.

Tracheobronchial Fibrosis

Tracheobronchial fibrosis includes that occurring within or about the tracheobronchial tree as far distally as the smallest bronchioles.

Roentgenograms may show an increase in the bronchovascular markings caused by endobronchial disease with irregular surrounding zones of infiltration representing residual inflammation. If

this is not extensive and if other complications are absent, pulmonary disability may not occur.

If bronchial or bronchiolar fibrosis is complete or if bronchial drainage is inadequate because of rigidity of the wall and destruction of the ciliary epithelium, obstructive pneumonitis will occur distally, with further impairment of pulmonary function. The final result of this process is a contracted fibrotic pulmonary segment.

Bronchiolar fibrosis frequently is diffuse and, although complete obstruction does not occur, expiratory obstruction is present, leading to diffuse emphysema. Emphysema is known to be a frequent late complication of numerous inflammatory processes, notably tuberculosis and chronic non-specific bronchitis.

As a consequence of the bronchiolar obstruction, the peripheral lung may become overdistended, with pronouncedly uneven ventilation of the alveoli, producing first ventilatory failure and finally alveolorespiratory failure. Patients who have tracheobronchial fibrosis have repeated infections, cough and progressive dyspnea. There often is evidence of poor thoracic expansion, distant breath sounds, delayed expiration and sometimes even wheezing as respiration becomes rapid with exertion. Clubbing of the extremities occurs in some cases of diffuse fibrosis with emphysema. Polycythemia, when present, usually is associated with *cor pulmonale*.

Results of Pulmonary Function Tests.—With mild emphysema, ventilatory failure ensues without alveolorespiratory failure. The total pulmonary capacity is normal or slightly increased, with a reduced vital capacity. If fibrosis is predominant, the total capacity may be reduced. The ratio of residual volume to total capacity is increased. The maximal breathing capacity is decreased to a greater degree than is the vital capacity. There is spirographic evidence of slowing of expiration and trapping of air. The alveolar concentration of nitrogen after the patient breathes pure oxygen for seven minutes is greater than the normal upper limit of 2.5 per cent. The physiologic dead space in the lungs is increased by the increased ventilation of relatively poorly perfused alveoli, and the diffusing surface is reduced by the rupture and coalescence of alveoli.

As the disease advances, compensation no longer can be maintained and arterial hypoxia ensues with exercise, and ultimately at rest. Despite hy-

poxia, a normal arterial carbon dioxide tension is maintained for a time by hyperventilation of essentially normal alveoli. Still further in the progress of the disease, the compensatory excretion of carbon dioxide is no longer adequate and hypercapnia becomes evident.

Etiology.—Intrinsic endobronchial diseases such as chronic asthmatic bronchitis, chronic bronchitis, bronchiectasis, and bronchiolectasis may be associated with bronchial fibrosis and often with fibrosis of the distal pulmonary parenchyma. Chronic fibrocystic disease of the pancreas often is associated with bronchitis and bronchiectasis. Two of the pneumoconioses are characterized by an endobronchial reaction. The first is bagassosis, which is an acute illness resembling viral pneumonia following variable exposure to the inhalation of particles of dust from the waste of sugar cane, known as bagasse.¹¹ While this is usually a brief illness with complete recovery, it gives pathologic evidence of endobronchial fibrosis surrounding superficially embedded spicules of bagasse. The second is byssinosis, a disease of workers in the cotton industry developing after many years of exposure.¹² It is a form of chronic bronchitis, often complicated by emphysema, that occurs transiently after the first exposure only to recur later, gradually becoming irreversible. The exact mode of action is unknown, but a specific allergy has not been demonstrated. While the incidence of the disease among workers exposed to cotton dust indicates an etiologic relationship, only the nonspecific findings of chronic bronchitis and emphysema are present at necropsy. Other pneumoconioses, such as silicosis, are associated with endobronchial lesions complicated by severe emphysema. Thermal energy from fire has caused acute tracheobronchial burns with secondary fibrosis.

Interstitial Fibrosis

Interstitial fibrosis denotes lesions involving primarily the alveolar walls, although the fibrosis may extend into the finer airways in some cases. Alveolocapillary block is a syndrome in which there is an impediment to the diffusion of oxygen across the alveolocapillary barrier. Clinically, symptoms are often out of proportion to the roentgenographic findings. Exertional dyspnea, cough, weakness, fatigability and exertional cyanosis are prominent. Digital clubbing and polycythemia are sometimes present in more advanced disease.

Results of Pulmonary Function Tests.—These patients show no spirographic evidence of respiratory slowing or trapping of air. They have normal or small residual volumes, and the ratio of the residual volume to the total capacity usually is normal. The alveolar concentration of nitrogen after the patient breathes 100 per cent oxygen for seven minutes is less than 2.5 per cent. The arterial oxygen saturation is less than normal at rest, decreases sharply with slight exercise and increases to normal when the patient breathes 100 per cent oxygen. The arterial carbon dioxide tension is normal or even low, since these patients tend to hyperventilate both at rest and with exercise.

Etiology.—Acute viral pneumonias are characterized by an acute alveolar, septal and peribronchial reaction. Influenza, measles, primary atypical pneumonia, scrub typhus and psittacosis have been described as showing edema, thickening and mononuclear infiltration of the alveolar wall. Similar involvement of the bronchial wall is noted with variable degrees of intrabronchiolar exudate. Mononuclear alveolar exudates or a hyaline membrane may be present. While many observers consider these lesions to be the precursors of interstitial fibrosis, the evidence remains scanty.

Berylliosis, in the acute phase, is capable of producing a boggy lung with intra-alveolar mononuclear exudation and interstitial edema.¹³ Chronic exposure may produce a fibrotic reaction. Chronic beryllium granulomatosis exhibits fibrinoid granular central necrosis surrounded by fibroblasts, lymphocytes, plasma cells, giant cells and conchoidal bodies.

Eight patients treated with hexamethonium, alone or in combination with hydralazine (apresoline) hydrochloride, had interstitial fibrosis that was indistinguishable pathologically from the Hamman-Rich syndrome.^{14,15}

Following exposure to radiation, acute swelling and necrosis occur in the alveolar epithelium and capillary endothelium. With a sufficient dose, edema of the alveolar walls and formation of an intra-alveolar hyaline membrane are seen. The injury heals by scarring.

Scleroderma produces alveolar and peribronchiolar fibrosis resembling the changes seen in the skin and other organs. Vascular thickening and emphysematous changes have been reported. The lacelike honeycombed appearance of the lower two

thirds of the lung fields caused by fibrosis of the alveolar walls and cystic emphysema are said by Pugh¹⁶ to be distinctive. Other workers, however, consider that the roentgenographic changes are not diagnostic.

The lipoidoses, particularly eosinophilic granuloma and Hand-Schüller-Christian disease, may induce alveolar and peribronchiolar reactions, consisting of xanthogranulomas containing dense histiocytic centers surrounded by eosinophils and fibroblasts. In addition to septal fibrosis, cystic emphysema often occurs secondary to involvement of bronchiolar walls. The roentgenographic appearance has suggested the term "honeycombed lung."

Tuberous sclerosis has been reported as a cause of "honeycombed lung"; necropsy may reveal bullae of various sizes surrounded by septa as much as 1 cm. in thickness containing vessels, small bronchi and smooth-muscle tissue.

Congenital alveolar dysplasia of the lungs is a form of fetal arrest with immature alveoli having thick septa. Interlobular walls are prominent and consist of immature connective tissue. While signs of inflammation are absent, some authors attribute the condition to intra-uterine infection. The milder forms are considered compatible with life and may appear as interstitial fibrosis.

Hamman and Rich¹⁷ described an idiopathic form of interstitial fibrosis characterized by (1) inflammation with edema and but few leukocytes, unlike the ordinary pneumonias, (2) cuboidal appearance of the alveolar epithelium, (3) necrosis of alveolar and bronchiolar epithelium, (4) presence of hyaline membranes, (5) edema and fibrin in the alveolar wall, (6) extensive diffuse progressive interstitial fibrous proliferation, (7) eosinophils in the interstitium and (8) absence of stainable bacteria. Numerous case reports of this syndrome have appeared subsequently, stressing or deleting some of the original criteria but emphasizing a pronounced interstitial fibrous reaction as the predominant pathologic change. While the disease in the originally reported cases was rapidly fatal, some subsequent patients have lived as long as nine years.¹⁸⁻²⁰ Although the cause is still unknown, most speculation implicates a preceding interstitial pneumonia. A familial incidence is evident. The response to steroids has been variable, and only a few patients with predominantly inflammatory lesions have benefited, only to have

exacerbations despite continued treatment or on withdrawal of the medication.

Vascular Fibrosis

A number of clinical entities are associated with pulmonary fibrosis originating in the vasculature. Secondary fibrosis of other structures may occur but circulatory abnormalities usually predominate. Increase of the pulmonary arterial pressure with subsequent failure of the right ventricle, end-diastolic right ventricular hypertension and, finally, peripheral edema, ascites and hepatomegaly may occur as a result of the various types of fibrosis or pulmonary emphysema. In these instances, the pulmonary hypertension follows obliteration of the vascular bed by fibrosis of surrounding structures, rupture of capillaries and vasoconstriction secondary to hypoxia. With primarily vascular fibrosis, actual cicatrization occurs about the pulmonary arterioles, with restriction of much of the vascular bed.

Etiology.—Pulmonary infarction and resulting fibrosis may be produced by pulmonary embolism, multiple emboli in the "main-line" drug addict, periarteritis nodosa and the thrombotic occlusion of polycythemia vera and sickle cell anemia.

Emboli small enough to be limited to the arterioles do not cause infarction but rather produce an inflammatory endarteriolitis. Fat and alantoic embolization and schistosomiasis, with microscopic emboli, are examples of conditions that produce perivascular interstitial fibrosis. Lymphogenous metastatic carcinoma, producing variable degrees of "perilymphatic" fibrosis, actually may represent minute pulmonary arteriolar emboli of malignant tissue.

Pulmonary vascular intimal proliferation may result from long-standing increases in the pulmonary blood flow secondary to intracardiac shunts. The "back pressure" in the pulmonary vascular system with left ventricular failure or with mitral stenosis induces chronic fibrous thickening of the vessels, as well as nodular collections of hemosiderin-laden phagocytes in the perivascular interstitium. In periarteritis nodosa, the nodular inflammatory and fibrous thickening of the vessel walls produces perivascular fibrosis, as well as distal infarction. Similarly, chronic perivascular fibrosis occurs in long-standing ascariasis after the insult of repeated larval migration.

The pulmonary manifestations of the "collagen diseases" are worthy of mention. Periarteritis

nodosa and scleroderma have been referred to. Disseminated lupus erythematosus may produce pleurisy and pneumonia associated with atelectasis, but evidence as to ultimate fibrosis is lacking. Many pulmonary complications of rheumatoid arthritis have been described but none with a specific rheumatoid lesion. Conversely, a rheumatoid syndrome is a common complication of many pulmonary diseases, such as tumors, particularly mesotheliomas, interstitial fibrosis and the progressive massive fibrosis of advanced silicosis.

The eosinophilic infiltration of Löffler's syndrome, and the lesions of Wegener's granulomatosis²¹ and all the variants of interstitial granuloma with angiitis, such as respiratory-renal polyarteritis nodosa, rheumatic vascular inflammation, paraneuritic disorder and allergic granulomatosis, are thought to be manifestations of a hypersensitivity reaction that may be classified under the heading of pathergic granulomatosis.²² Variable degrees of perivascular pulmonary fibrosis may occur in the more persistent of these syndromes.

Comment and Summary

Pulmonary fibrosis is the formation of scar tissue in the lungs of sufficient degree to be characterized clinically by abnormal roentgenographic shadows or physiologic impairment or both. It is distinguished from the diffuse pulmonary diseases that also include edema, exudation and inflammation. Fibrosis is suggested clinically by the prolonged duration of physiologic or roentgenographic abnormalities, but a definitive diagnosis must be supported by histologic proof.

Pulmonary fibrosis has been classified into four pathophysiologic groups. Parenchymal lesions, the first group, are focal in distribution and leave zones of relatively normal intervening lung. These lesions usually result in symmetrically decreased lung volumes and hyperventilation, but otherwise the pulmonary function is normal. In general, the roentgenographic abnormalities exceed the physiologic and clinical evidence of disease. Pyogenic, tuberculous and mycotic infections, silicosis and sarcoidosis are the main causes of parenchymal pulmonary fibrosis.

The second group, namely tracheobronchial lesions, result in focal or diffuse narrowing of the airways, producing distal atelectasis or emphysema. The increased work of ventilation is reflected in slowing of expiration and decrease in maximal

breathing capacity. There are increases in the ratio of residual volume to total capacity and in the index of intrapulmonary mixing of gases. Alveolorespiratory failure, with arterial hypoxia, and finally hypercapnia ensue. Chronic bronchitis, bronchiectasis and some pneumoconioses are the main causes of tracheobronchial lesions.

Interstitial fibrosis, the third group, is manifested by involvement of the alveolar walls, resulting in a diminution of gaseous exchange. Significant hypoxia and symmetrically decreased lung volumes are the main abnormalities. Viral and rickettsial pneumonias, berylliosis, radiation pneumonitis, scleroderma and the Hamman-Rich syndrome are the common causes of interstitial fibrosis.

Vascular fibrosis, the final group, results from emboli, thrombi and many of the collagen diseases and may lead to failure of the right side of the heart.

The clinical problem of pulmonary fibrosis involves etiology and prognosis. The clinician's first duty is to exclude contagious infections and malignant tumors. Smears, cultures and cytologic examination of sputum, cultures of gastric washings, skin tests and a general examination often determine the specific cause. Asymptomatic, nonprogressive fibrosis that is neither infectious nor malignant need give no further concern. Symptoms of pulmonary insufficiency or evidence of roentgenographic progression, however, demands additional study.

A careful history and physical examination may disclose a previous infection, an occupational exposure or a generalized disease of which pulmonary fibrosis is only one manifestation. In many instances, however, a specific etiologic diagnosis cannot be made. Biopsy of the scalene lymph nodes or the lung may help uncover the cause of obscure fibrosis. While not always definitive, histologic evaluation, when coupled with estimates of physiologic impairment and clinical progression, usually permits a reasonably accurate prognosis.

Continuation Studies

Some Electrocardiographic Tests of Coronary Insufficiency

ALAN P. RUSTERHOLZ, M.D.
Saint Paul, Minnesota

IT IS OFTEN important and extremely difficult to determine whether angina pectoris exists, or whether a patient's discomfort is caused by one of about two dozen other entities that may mimic it. As a rule the patient's history and response to nitroglycerine are most helpful, but in atypical cases or in cases without any pain, other diagnostic methods are required. A twelve lead resting electrocardiogram is often perfectly normal in the presence of severe coronary sclerosis. However, certain electrocardiographic changes are often transiently present during episodes of angina pectoris. These abnormalities consist of ST segment depressions and the tendency to inversion of T waves in leads facing the left ventricle. This is the pattern of subendocardial ischemia. Due to its anatomical placement at the end of the line, it is the subendocardium that suffers first when the oxygen supply is deficient.

Numerous investigators have attempted to take advantage of this fact by devising tests by which the electrocardiographic response to stresses of various kinds is recorded. Two main types of such tests will be described, the first one briefly.

The hypoxia test devised by Levy consists of inducing the resting patient to breathe a mixture containing 10 per cent oxygen. An electrocardiogram is made before the test at basal conditions, and after breathing 10 per cent oxygen for five, ten, and twenty minutes. The test is terminated if chest pain occurs, and the patient can be given inhalations of 100 per cent oxygen if necessary. The popularity of the hypoxia test has waned recently because the various exercise tests appear to be more reliable and somewhat less dangerous. Pulmonary edema, peripheral vascular collapse, and generalized convulsions have been precipitated by the test.

The following are considered to indicate an abnormal Levy test:

1. ST depression totaling 3 mm. or more in leads I, II, III and CF_4 ,
2. inversion of T_1 or TCF_4 , or
3. partial inversion of T_1 or TCF_4 , provided the lead in question displays at least 1 mm. ST depression.

Other investigators have devised exercise tests of many types, including such exercises as running up two flights of stairs, stooping, stair climbing, bending, et cetera. Some men attempt to fit the exercise to the activity that usually precipitates the patient's pain.

Perhaps, the best known of the exercise tests is the two-step test devised by Dr. Arthur Master. The test consists of having the patient make a predetermined number of trips over two nine-inch high steps in ninety seconds. The number of trips is read from tables, and depends upon age, sex, and weight. A resting 12 lead cardiogram is taken just before the test and is read. Unless this tracing is normal, the test is cancelled. The lead cord is then disconnected from the machine and carried by the patient as he walks over the steps, electrodes in place on his extremities. After completing the exercise, he lies down and a few beats of leads II, V_4 , V_5 , V_6 are recorded as quickly as possible. Haste is important here as evanescent abnormalities often occur that may otherwise be missed. Only enough complexes must be taken to produce a level base line in each lead. The four leads are again taken at two and six minutes post exercise. If the test is considered normal, a double Master test is done at least an hour later. In the double test, twice the number of trips are made in twice the time, i.e., three minutes. Master states that a negative double two-step test *practically* excludes significant coronary disease.

Master's criteria for abnormality differ from Levy's and are essentially:

Presented at the Continuation Course in Electrocardiography, University of Minnesota, May 7-11, 1956.

1. ST depression of 0.5 or more mm. in any lead.
2. T wave inversion in any lead.
3. Production of blocks or of various arrhythmias.
4. Miscellaneous poorly understood changes such as ST elevation or perhaps paradoxical behavior of T waves, i.e., a negative T becoming upright.

Fig. 1. Lead 2 from a case of chronic pulmonary hypertension, showing huge peaked P waves. Atrial T waves can be seen as inverted smooth waves beginning .05 to .06 seconds before the peak of the R wave and terminating .12 seconds after the peak of the R. These atrial T waves are larger and more easily identifiable than those usually seen because the size of the atrial T wave is proportional to the size of the P wave.

Changes are normally seen after exercise and involve all of the electrocardiographic deflections:

1. The P wave becomes higher, and right axis deviation of the P wave occurs.
2. The P_T wave increases in size.
3. The PR interval shortens.
4. The PR segment becomes depressed.
5. The QRS duration decreases.
6. The ST segment becomes depressed.
7. The T wave becomes lower, then higher, and then lower.
8. The QT interval and the U wave show variable changes. Usually the U wave becomes higher.

Most of these changes are so slight that they are not detected without special measuring devices. ST depressions and T wave lowerings, however, are often of considerable magnitude following exercise. Inasmuch as ST and T changes are also seen in spontaneous angina pectoris and as a result of the test in question, assigning the correct etiology to observed changes can be very difficult.

The following factors may make measurement of ST depression difficult or impossible:

1. Due to tachycardia, the P wave may occur on the descending limb of the preceding T wave. This causes the most logical isoelectric line, the T-P segment, to disappear.
2. A U wave may become elevated, obliterating the T-P segment; therefore the level of the PR

segment should be taken as the base line.

3. The PR and ST segments may become depressed because of increased voltage of the auricular T wave, which is negative.

Fig. 2. (a) resting; (b) immediately after exercise; (c) two minutes later. Positive test showing inverted U wave immediately after exercise. (The ST segment at rest is not strictly normal). Exercise tolerance tests are usually not performed in such cases.

Fig. 3. (a) resting; (b) immediately after exercise; (c) two minutes later. Positive Master Test showing more marked abnormality at two minutes than immediately after exercise.

Most authors consider Master's criteria to be too strict and consider ST depressions of up to 1.5 or 2 mm. as normal or borderline. Production of a negative U wave should also be considered abnormal.

It stands to reason that if one calls very minor ST depressions abnormal, he will err on the side of having relatively many false positives; conversely, if one requires considerable ST deviation, his mistakes will be predominately false negatives.

Dr. Gordon Myers has approached the problem somewhat differently and places emphasis on the contour of the ST segment. He feels that an ST segment that is concave superiorly and runs

Fig. 4. Master test showing positive result including episode of ectopic rhythm, probably ventricular tachycardia. (a) Lead V_4 resting. (b) Immediately after exercise. The third complex of lead 3 inaugurates a burst of ventricular tachycardia. V_4 is shown for comparison with the previous and subsequent strips. (c) Lead V_4 , two minutes after exercise. Sinus rhythm has returned, but ST and T waves are abnormal.

smoothly into the ascending limb of the T wave is likely to be normal, and that an ST segment that is horizontal or slopes slightly downward is probably abnormal.

A further source of confusion is evident in that Dr. Master states that a positive test may mean either organic or functional coronary insufficiency. It would seem almost as difficult to separate organic from functional coronary insufficiency in the positive Master test as to separate the pain of coronary insufficiency from the pain caused by various noncoronary entities.

Dr. Master has used the adrenolytic drug dihydroergocornine to accomplish this. He reports positive two-step tests which are repeated following administration of hydrogenated ergot derivatives. In certain cases the test then becomes negative. These cases are called instances of functional coronary insufficiency.

In conclusion, the most widely accepted electrocardiographic test for coronary insufficiency is the Master two-step test. It has the advantages of simplicity, safety, and standardization. It can be used to evaluate coronary vasodilator drugs. In common with most similar tests, it does not prognosticate.

The amount of stress applied depends only on age, sex, and weight, whereas many investigators feel that one cannot justifiably ignore the degree of coronary narrowing present in a given patient. They also consider that the oxygen requirement is proportional to the work of the heart, and depends upon the patient's emotional reaction, the condition of his autonomic nervous system, and his degree of physical training.

Technically, the measurement of post-exercise changes is often difficult, and the evaluation of these changes once they are measured is equally perplexing. It is often in the most difficult cases clinically that one will encounter a false positive or a false negative result. In addition, the separation of positives caused by organic narrowing from those caused by functional insufficiency needs further study.

The Master test, then, is often helpful and too often disappointing. It is of greatest value when it supports the clinical impression and adds weight to a previously established diagnosis.

One should, however, be somewhat hesitant to accept a Master test that contradicts a well formed clinical impression.

Injuries of the External Genitalia

BAXTER A. SMITH, JR., M.D.
Minneapolis, Minnesota

THE GENITALIA, because of location and mobility, are seldom injured. To the injured, molehill damage may assume mountainous proportions and sometimes the main problem is psychic.

Skin

The rotating shaft with set screw is a hazard to boys and adults. The individual steps over the unguarded power take off and the set screw catches the overalls removing them and the skin of the penis and scrotum, usually leaving the preputial mucosa and a few tags of scrotum, but not otherwise injuring the testes or penis. Cleansing and hemostasis are performed, and skin graft from a rather hairless area to the penis is necessary as a rule. The testes may be covered with freed thigh skin and scrotal tags. All scrotal skin should be saved because the scrotum has remarkable healing and regenerative powers.

Constricting injury to the penis is not uncommon. The constricting mechanism is applied, and soon edema prevents removal. Dr. Richardson removed a Timken bearing with the aid of general anesthesia, water cooling, multiple dental carborundum discs, and patience.

Bites may cause great edema, and at times, infection. Despite massive edema, urination is usually uneventful. The outdoor facilities in the south frequently harbor the black widow spider. In case of a spider bite cold applications may be warranted to delay absorption if the situation is recognized early enough.

Lacerating injuries, common in war, are usually caused by land mines, booby traps and shell fragments. The automobile, irate husbands and wives, and playful companions are the most common offenders in civil life where cutaneous destruction is seldom serious.

Penis

The penis is sometimes amputated by the insane or irate, and blood loss may be fatal. If severance is partial, attempt at salvage is often

successful. Debridement and suture of the fascia of the corpora with catheter splinting of the urethra and pressure dressing using mechanics waste is done. Penetrating and lacerating wounds involving the penis itself are similarly treated.

Fracture of the penis is an uncommon but arresting injury. History of the mechanism is frequently vague, and delay in seeking help is common. The one requisite is erection. An audible snap or pop is usually reported. Pain, swelling, and hematoma are prompt, and the penis is no longer erect but is deviated to the side opposite the fracture. Deviation increases as the hematoma enlarges. Recognition is usually easy if the hematoma is not too large. Pressure bandaging, with indwelling catheter, suffices if the hematoma is not large. Frequently hemorrhage is massive in which event evacuation of clot and suturing of Buck's fascia is done. Impotence appears to be a common sequela, as with many genital injuries.

Urethra

The bulbous and pendulous urethra may be damaged by penetrating and lacerating wounds, chemicals, instrumentation, foreign bodies, and straddle injury.

In all penetrating-lacerating wounds of the genitals, perineum, and pelvic area, one should promptly ascertain the integrity of the urethra. If unrecognized, urethral injury may be the most serious damage inflicted. This is particularly true of the deep urethra. In the distal urethra the diagnosis is readily made and the mechanism is the same as penile injury. Since the advent of antibiotics in the treatment of gonorrhea, chemical trauma is rare, but when it occurs it results in severe stricture formation over long areas.

Urethral instrumentation should be gentle at all times. False passages compound the difficulty with strictures and severe strictures may be caused by instrumentation, usually the employment of a scope too large for the urethral caliber. Inlying catheters, especially in the paraplegic, may in-

jure the mucosa at the peno-scrotal angle by pressure with resulting abscess, fistula, or diverticulum formation; therefore, the inlying catheter, no larger than 18 Fr., should be brought over the thigh in the inguinal region. The presence of foreign bodies, hat or corsage pins, swizzle sticks, et cetera, is usually self evident, though history may not be given. Foreign bodies may be removed endoscopically or by external urethrotomy done in the bulb.

Straddle injuries are associated with the board fence, construction beams, and wagon boxes and tongues. The urethral bulb is impinged against the inferior aspect of the pubis. Meatal bleeding and perineal pain, swelling, and ecchymosis occur. The hematoma in injury of the bulb is confined by Colles' fascia and accordingly involves the perineum, scrotum, ischio-rectal fossae, penis, and lower abdominal wall. Minor injuries are sometimes catastrophic.

Patients suffering urethral trauma should be given prophylactic antibiotics. If the urine is previously infected, ensuing sepsis may be grave. Penetrating-lacerating wounds should be cleansed, debrided and repaired with fine catgut over an inlying catheter if loss of tissue is not too great. In the latter case, diversion of the urine is necessary and may be by catheter if the proximal urethra can be located, otherwise by cystostomy. The complications of instrumental trauma may be partially avoided by the use of a small inlying catheter for one to two days. The urethral catheter should never be so large as to preclude urethral drainage.

The treatment of straddle injury depends upon the extent of tissue damage. The patient should be cautioned against trying to void. Frequently a catheter can be passed gently and left indwelling for three or four days, and this maneuver should be tried. Large hematomas should be drained in the perineum, not in the scrotum where the swelling may be greatest. The individual suffering straddle injury seldom has shock and complicating fractures, so he may usually be placed in the lithotomy position. If the contusion is marked, high suprapubic cystostomy is advisable, preferably splinting the urethra. This may be accomplished by passing a sound downward through the cystostomy and another upward through the distal urethra. When they are felt to click, the penile sound follows the other by clicking con-

tact, and the tip is protruded through the cystostomy wound. A catheter is tightly fitted over the tip of the sound and withdrawn through the urethra. Usually it is preferable to sew to this catheter a Foley catheter, 18-20 Fr., which may be drawn into the bladder and left indwelling for eight to ten days. Drainage of the perineal hematoma is advisable. In lesser injury, the perineum may be explored and catheter passage and repair attempted under vision; however, the infiltration of the loose tissues with blood makes recognition of the proximal end of the urethra difficult. In all injuries to the urethra, the adequate care of the resulting stricture is of the utmost importance.

Scrotal Contents

The scrotal contents are sometimes damaged in surgery, particularly in hernioplasty when the vas or testicular blood supply may be disrupted. Penetrating-lacerating injuries are most common in war, vehicle accidents, and attempts at emasculation. The arterial supply to the testis enters the hilum, then branches and runs in the inner layer of the tunica albuginea to the "anti-mesenteric" area where it then penetrates the parenchyma. Testis wounds should be debrided and any tissue with potential viability conserved, closing the tunica albuginea. This is most important when the trauma is bilateral. Freshened ends of the vas can be approximated by fine silk sutures after splinting the defect with a nonabsorbable suture brought out through the vas wall proximally and distally and then brought through the skin for removal in a week.

Hematocele is an accumulation of blood within the tunica vaginalis and is usually very painful due to pressure. It may occur with or without rupture of the tunica albuginea and may be rather slow in developing. The mass does not transilluminate. Aspiration may be successful since the blood may remain liquid in slowly forming hematoceles, but evacuation of clots and hemostasis are preferable if the condition can be separated from scrotal hematoma. In the latter, pain is less and the scrotum feels less weighty. A chronic organized hematocele is most difficult to differentiate from testicular tumor.

So-called "traumatic epididymitis" is of considerable industrial importance. There are opinions

Roentgen Findings in Leiomyosarcoma of the Pancreas

S. B. FEINBERG, M.D.
A. R. MARGULIS, M.D.
P. LOBER, M.D.
Minneapolis, Minnesota

LEIOMYOSARCOMAS are not unusual in tissues in which smooth muscle predominates, but they are quite unusual in the pancreas. As it may be of importance to include this entity in the differential diagnosis of pancreatic masses, we feel it is warranted to report a case.

Ross¹ has reported the pathologic findings of a single case of leiomyosarcoma of the pancreas in an aged diabetic male who had widespread metastases, including skin nodules. No roentgen examinations were done. Weintraub and Tuggle² briefly mentioned leiomyosarcoma of the pancreas as one of the twenty cases of neoplasm involving the duodenum.

The paucity of reports of the literature indicates that the condition is quite rare. This is a tumor of low grade malignancy. Consideration of this entity in the differential diagnosis may be of practical value. Observation to follow enlargement of a possible "pancreatic cyst" is obviously not the treatment of choice.

Case Report

E. F. is a fourteen-year-old white boy who was admitted to his local hospital after a two-week history of dull epigastric pain and nausea. He had a bout of jaundice and light stools with subsequent spontaneous remission of his jaundice. His preoperative hemoglobin was 7 Gm. At surgery, a hard pancreatic mass was found and he was transferred to the University of Minnesota Hospitals. On admission the only finding was that of an obvious epigastric mass. No icterus was apparent. Laboratory findings were as follows: Sedimentation rate 8.5 mm/hr, hemoglobin 16.1 Gm., serum albumin 2.1 grams per cent, serum globulin 6.4 grams per cent, alkaline phosphatase 19.9 K.A.U., total serum bilirubin 0.5 mgm per cent, and glucose 80 mgm per cent. The radiographic findings were those of a well circumscribed rounded mass in the head of the pancreas. As such it displaced and widened the duodenal loop. The second portion of the duodenum was pushed laterally and anteriorly. The ligament of Treitz being to the left of the lesion was not displaced. There was

anterior and left lateral displacement of the gastric antrum.

Since adenocarcinoma of the head of the pancreas does not occur in this age group, the tentative preoperative radiologic diagnosis was that of a cyst of the head of the pancreas, a cystadenoma of the head of the pancreas, a rare tumor that occurs in childhood,³ or a retroperitoneal sarcoma invading the pancreatic bed.

The value of this case from a roentgen standpoint is the inclusion of this rare tumor in the differential diagnosis of lesions of the head of the pancreas.^{2,3} It is to be kept in mind, however, that the lesion elsewhere in the pancreas could produce several different configurations. According to Case,⁴ they could fall into gastrophilic, gastroduodenal, gastrosplenic, and mesocolic types.

Figure 1 shows extrinsic compression of the right kidney and considerable displacement to the right of the duodenal bulb.

Figure 2 demonstrates the posterior mass flattening and displacing the second portion of the duodenum anteriorly. This in itself pinpoints the mass, since the second portion of the duodenum is a retroperitoneal structure whose mesentery has been resorbed and only the parietal peritoneum covers the anterior surface of the duodenum.

Figure 3 shows a more familiar appearance and is classic for a lesion of the head of the pancreas: widening of the duodenal loop and anterolateral displacement of the antrum.

Dr. Bernard Zimmerman performed a laparotomy and found a large round encapsulated tumor to the left of the duodenum in the head of the pancreas. It extended to the left of the superior mesenteric vessels. There was only a small segment of normal pancreas. A radical pancreato-duodenotomy, Whipple type, was done. His recovery was uneventful. The surgical specimen consisted of the head of the pancreas and duodenum, with attached portions of common bile duct, stomach and jejunum. There was a large rounded tumor measuring 11 x 10 x 9 cm. in the head of the pancreas. This was sharply circumscribed. Compressed pancreatic tissue lay over the tumor. The walls of the duodenum, common bile duct, and major pancreatic duct were completely independent of the tumor. The major pancreatic duct was small and displaced posteriorly. On the cut surface, the tumor was greyish-white in color, fibrous in character, and firm in consistency. In the center was an area of cystic necrosis about 3 cm. in diameter. The microscopic sections of the tumor showed it to be composed of intertwining fasciculi of spindle-shaped cells and

From the Departments of Radiology and Pathology, University of Minnesota Hospitals.

Fig. 1. An anterior-posterior film of an excretory pyelogram shows extrinsic compression of the right kidney without displacement, superimposed mass margins (arrows), and displacement of the duodenal bulb to the right (arrows).

Fig. 2. Lateral view of an upper gastrointestinal series. The duodenojejunal juncture (arrows) is not displaced, but the pars media of the stomach is effaced and anteriorly displaced.

Fig. 3. An oblique view of the stomach and duodenum shows marked widening and stretching of the second portion of the duodenum.

fibers. There was a moderate amount of cytoplasm which was elongated, strap-like and eosinophilic, resembling smooth muscle. The nuclei were oval or spindle-shaped and occasionally showed blunt ends. Some of these showed variation in size and there were occasional mitotic figures. Some nuclei were large and rounded, with prominent nucleoli. The tumor in some areas had a loose structure while elsewhere it was more densely cellular. Multiple sections showed no other elements in the tumor. It was only moderately vascular. These seemed to be a thin capsule about the tumor of compressed fibrous tissue, containing some pancreatic acini and islets of Langerhans. The tumor appeared to be independent of the muscular walls of the duodenum and common bile duct and separated from them by its capsule and loose areolar tissue.

This is believed to be a smooth muscle tumor which is considered malignant because of pleomorphism of the cells and evidence of growth activity. It appears to be of a low grade of malignancy, however, and there is no present evidence of spread beyond the primary location. Dissection does not reveal any gross structure of origin. The origin of this tumor is obscure but might be from the smaller pancreatic ducts or from vessel wall.

Conclusion

A case of leiomyosarcoma of the pancreas in a fourteen-year-old boy is presented with particular attention to the roentgen and pathologic findings.

Case Studies, Minneapolis Veterans Hospital

Edited by
CLAUDE HITCHCOCK, M.D.

MESOTHELIOMA

Case 1.—This young man first entered the Minneapolis Veterans Hospital during 1952 at the age of twenty-seven. He complained of a dull, crampy abdominal pain and abdominal distention gradually increasing for the previous two to three months. Examinations of liver and kidney functions at this time were within normal limits and upper gastrointestinal x-rays and barium enema x-ray examinations were also normal. A bone marrow biopsy was performed and was found to be normal.

The past history of this patient was of interest. For fifteen years, he had recurring ascites requiring paracenteses at two- to three-year intervals. At the age of twelve, he had been told that he had kidney disease. In 1945, while he was in the army, he had an episode of dull, aching abdominal pain, and some distention was noted at that time. Several paracenteses were done, and a biopsy of the peritoneum through a peritoneoscope was interpreted by the pathologist as a mesothelioma of the peritoneum.

When the patient was presented to the Tumor Conference at the Veterans Hospital in 1952, the tumor board members decided that there was not enough evidence to substantiate the diagnosis of a true mesothelioma of the peritoneum. The patient was discharged, after a paracentesis, with a diagnosis of intermittent ascites of undetermined etiology.

The patient was again admitted to the Veterans Hospital in 1954 with diffuse abdominal pain that finally localized to the right lower quadrant. On this admission, there was definite tenderness to palpation with some spasm and rebound tenderness present in the abdominal muscles. The patient was operated upon, and on opening the abdomen a thick mucoid fluid was found. The entire peritoneal cavity and its contents were noted to be involved with a granulomatous type of peritonitis. Several of these nodules were removed, and sections showed them to be composed of low columnar cells with deep-staining nuclei and abundant pink-staining cytoplasm. The final diagnosis at this time was mesothelioma of the peritoneum.

Following surgery, the patient's symptoms subsided and he was able to return to his normal occupation as a truck driver. Recurring abdominal distention due to ascites has necessitated his return to the hospital for paracenteses on two occasions since operation. When last seen in February, 1957, he was anemic and required several blood transfusions. During the past year, he has lost ten pounds of weight but he still is able to carry on his work.

Discussion.—The diagnosis of mesothelioma of the peritoneal cavity is almost impossible to establish definitely in an antemortem clinical situation. It is far more common to have extensive and diffuse peritoneal metastasis from visceral cancer in the abdominal cavity than it is to find mesothelioma. Furthermore, the peritoneum has a great capacity to undergo metaplasia and to form papillary projections and pseudo-acini, and on occasion even to show squamous metaplasia. The long history of peritoneal involvement in this present case and the findings at surgery of a diffuse and granulomatous

involvement of all the peritoneum stimulated the physicians caring for this young man to consider his problem that of a mesothelioma of the peritoneum. One can infer from the recent clinical course that the tumor is probably malignant, and the patient's condition seems to be worsening at this time.

The description of this tumor indicated that it is most likely the papillary type of mesothelioma, if the diagnosis is correct. However, it must be emphasized that the primary papillary malignant mesothelioma can be simulated very closely by metastatic carcinoma. In addition, it must be recognized that primary benign mesotheliomas exist, as was pointed out in 1935 by Wells. Another type of mesothelioma that can occasionally be cured by surgical excision is the fibrous type reported by Stout in 1951. Willis still believes that primary peritoneal tumors do not exist. In this particular case, the clinical duration of the disease, the microscopic pattern, and the evolution of what appears to be a malignant peritoneal tumor probably warrants the diagnosis of mesothelioma of the peritoneum. It will be of interest to have a thorough examination of all tissue in this patient's body at the time of death, and if no primary source of carcinoma can be demonstrated, the consideration of this tumor as a primary malignant mesothelioma will be substantiated. Such a tumor would be worthy of reporting in the literature.

EOSINOPHILIC GRANULOMA

Case 2.—Pain in the right upper chest of two months' duration brought this twenty-five-year-old man to the Veterans Hospital for admission during January, 1957. A chest x-ray examination had been performed by the family doctor two weeks after the onset of pain and the x-ray findings indicated a normal condition. The pain, however, became progressively worse, radiated around the right side of the chest, and was accentuated by coughing. The pain became so severe that the patient had to stop work one week prior to admission to the Veterans Hospital and he again saw his family physician. A chest radiograph taken at that time showed a destructive lesion in the right ninth rib.

Physical examination failed to reveal a source of primary tumor, but there was considerable tenderness to palpation in the region just below the tip of the right scapula. The patient was studied with a skeletal x-ray survey, and no other lesions were found. An upper gastro-intestinal series x-ray examination and a barium enema x-ray examination revealed no abnormalities. An intravenous pyelogram showed a slight abnormality of the collecting system of the right kidney but an aortogram was performed and this was interpreted as showing a normal kidney. A bone marrow biopsy was also performed and this revealed a normal marrow.

Since no primary lesion could be found indicating a

TRANSAMINASE TEST

Current thought based on many thousands of tests is that the transaminase or glutamic-oxalacetic transaminase test is the single best laboratory aid for the diagnosis of coronary thrombosis. It does not replace the electrocardiogram. With the use of a commercially developed packet* of well-controlled chemicals and a simple colorimetric procedure, almost any laboratory with a competent technologist can now use the test.

Necrosis of heart or skeletal muscle, liver cells or pancreatic tissues releases relatively large amounts of the intracellular enzyme transaminase into the blood stream where it can be measured directly or indirectly by several different and sufficiently accurate chemical procedures. In both animal experiments and clinical experiences, there is a fairly close direct relationship between the size of a cardiac infarct and the height of rise of the serum transaminase. Unlike the previously widely used laboratory procedures in possible coronary thrombosis cases (red cell sedimentation rate, white blood cell count, and C-reactive protein), this test is practically specific for cell necrosis or serious cell degeneration. The organ site of the lesion must be identified by clinical means.

The time relationship of the apparent onset of coronary occlusion and the level of serum transaminase is of basic importance. The normal level of serum transaminase of from 10 to 40 units is exceeded in from 6 to 24 hours after the onset of symptoms of coronary occlusion. The level frequently reaches 200 to 300 units and occasionally may rise to 600 units. There is a return to normal levels in the average case within three or four days and practically always by the sixth day from the onset of the calamity. These levels and the time element may be of some help in differentiating heart from liver disease.

The test has its greatest critical value in the differentiation of myocardial infarction from (1) angina pectoris, (2) bundle-branch block,

(3) previous healed or healing myocardial infarction, and (4) pulmonary embolism. Active inflammatory diseases of the myocardium result in "positive" blood levels. Thus, the test is useful in the detection of active rheumatic myocarditis.

Bile normally contains large amounts of the enzyme transaminase. In pure mechanically produced jaundice, there is a moderate rise in the blood levels. Active infectious diseases (epidemic infectious hepatitis, homologous serum hepatitis, and infectious mononucleosis) of the liver are associated with extreme elevations in the serum levels to 2000 or more units and they may remain high for periods of many days or even weeks. The same is true in patients with liver injury due to chemicals such as chlorpromazine, pyrazimamide, carbon tetrachloride and cinchophen. Active cases of cirrhosis of the liver generally have very high levels. In other patients with cirrhosis, normal readings may be found. The test has been found "positive" in the great majority of patients with carcinoma metastases to the liver, in spite of the fact that in some instances the metastases are small.

The necrosis in most cases of acute pancreatitis results in abnormally high levels of serum transaminase. Diseases injuring or destroying kidney tubular epithelium should theoretically cause increases in serum transaminase; however, the medical literature has revealed surprisingly little value of the test in the diseases of this organ. The brain also contains large amounts of transaminase, yet there is no consistent variation in serum levels in cases of cerebral infarction. Recently, it has been found that the cerebral spinal fluid is flooded with the enzyme in these patients with cerebral infarction.

The goal in this experimental chemistry sphere of laboratory diagnosis now appears to be the isolation and measurement of enzymes peculiar to specific organs and tissues. Such specific tests may approach the pathognomonic evidence which we are continuously seeking for the diagnosis of disease.

CONFESSIONS OF A HOBBYIST

Radio

In the early 1920's, I found myself deep in radio. With a few comparatively inexpensive pieces of apparatus and a flair for experimentation, at that time one could put together a better receiver than any of the crude commercial sets then available. The listening was fun, even if one didn't listen to anything very long, and just "collected stations." One game was to scan the country to see how many high school orchestras were playing "Poet and Peasant Overture." Some of the names are forgotten now, but among them were Hazletine's Neutrodyne and David Grimes' Inverse Duplex circuit. On an impulse, in 1924, I cross-bred these two circuits, and stumbled on what bade fair to be the best circuit in the country. I couldn't do anything with it commercially because of patents, but it was a joy to amateur builders, and when a now extinct magazine, *Radio in the Home*, took it up, I found myself swamped with letters from all over the United States and Canada, from people building Inverse Duplex Neutrodynes. In one mail I would hear from a retired engineer, a priest, the janitor of a movie theatre, a dentist, an R.F.D. postman, and many others. In the IDN, four tubes did the work of six, which, in the days when a tube cost \$6.50, really helped. Reception was on a small indoor box loop. Two manufacturers became interested in what I was doing, and supplied bits of apparatus specially made, when what I wanted was not on the market. The circuit, for those days, had a singularly clear, pleasing tone. I worked at refining it for nearly two years, trying out each new improvement on Station CYL, Mexico City, where someone used to broadcast Beethoven Sonatas every Wednesday evening.

It was wonderful while it lasted. But Armstrong's "superheterodyne" circuit appeared, much easier to handle than the IDN, and it was getting to the point where further experimentation would require more knowledge of electrical engineering than I had, or would have time to acquire. The manufacturers, too, had caught up with and passed the amateurs, and rectifiers and multi-element tubes began to appear. Reluctantly, I dismantled my attic laboratory and began its transformation into a wood-working shop. I still have the original Inverse Duplex Neutrodyne, and if I could get the right batteries and speaker, it would

work today. I wonder how it would sound! I am humiliated to admit that when anything goes wrong with the Capehart that was given me when I had been twenty-five years at the Saint Paul Academy, I just yell for a service-man.

JOHN DEQ. BRIGGS

BOOKPLATE COLLECTING AND EXHIBITING

The first article in this series told of the origin of the bookplate 500 years ago in Europe. In America, we were not far behind. The "Steven Day label" is dated 1642. As time went on, numerous engravers were in the New England colonies and in and around New York, Philadelphia and Baltimore. The year 1749 is the earliest date by an American engraver: Nathaniel Hurd of Boston, known as the best of all those in Colonial times, cut the Thomas Dering plate. Paul Revere, who was a silversmith and engraver, was also in Boston, as we all know. High prices have been paid for the few plates known to be his work. They rank next to the bookplate of George Washington, the most highly valued American bookplate of the early period. The original metal plate which was used for the President's prints is now in the Metropolitan Museum of Art, New York City. There was a rumor that it was destroyed, but this has been definitely disproven.

The fact that bookplates are being used more and more does not mean that they are a new idea but that they are becoming more generally recognized in America. It is the same in other countries. Almost any month's mail will bring to a collector of bookplates, letters and prints from artists or collectors in Europe, even from Australia where there is a national society, and from Java also on the other side of the world, asking to exchange.

There is little expense to this collecting. The custom is to send back the same number of prints as received—one print if only one came, five or six if the sender enclosed five or six. Lists of persons wishing to exchange are often in the Year Books or Bulletins of such well-known organizations as the American Society of Bookplate Collectors and Designers* which has headquarters in Washington, D. C.

There is an Ex Libris Society in London which

*This Society was founded in 1922. The Secretary-Treasurer is Carlyle S. Baer, 3333 McKinley Street, N. W., Washington 15, D. C.

was established in 1890, and there are similar societies in other lands. Stimulus was given to both designers and collectors by the Bookplate Association International which, from its start in 1925 to 1936, inclusive, held yearly exhibitions of bookplates designed by workers in twenty-five countries, each represented by an honorary vice president. Fifty American artists usually participated. The prints became the property of the Association, which voted in October 1935 to give its collection of 6,015 prints to the University of California in Los Angeles.

In America, the Grolier Club of New York, which has an extensive collection, held the first public exhibition of bookplates in 1894. The Grolier Club was organized in 1884 for the study and promotion of the arts pertaining to the production of books, including the occasional publication of books designed to illustrate, promote and encourage those arts. The Club has always included among its activities the collection and exhibition of prints, and a large number of its members are print collectors. The Grolier Club maintains a clubhouse at 47 East 60th Street, New York, where it holds exhibitions from time to time which are open to members and the public, and where it maintains a library of more than 23,000 volumes of books relating to bibliography and the arts pertaining to the production of books. This collection is the outstanding one of its kind in the world. The Club also owns a large collection of prints of all kinds.

The American Bookplate Society (1913-1926) held annual exhibitions at the Avery Library of Columbia University, the Grolier Club or the National Arts Club, New York City, for ten years beginning 1916. The book fairs, such as the New York *Times* book fair at Radio City, Rockefeller Center, the Boston Book Fair and the Northwest Book Fair, exhibit bookplates.

Designer and Illuminator

CALENDAR HISTORY

Astronomers through the early centuries worked constantly to reconcile the calendar with the heavens, but all the time the inaccuracy of eleven minutes, fourteen seconds in the Julian Calendar began to pile up. By the 16th century, the year was ten whole days out of kilter.

The farmer who sowed, tilled and reaped ac-

cording to the feasts of the church was left in a whirl. The moon, sun and stars seemed to be off the beam. Seasons were all out of whack. His world was topsy-turvy and he was shocked to find that religion and agriculture just didn't hit it off any more.

The vernal equinox had been moving back because of the time lost in the Julian Calendar error. By 1500 the equinox set to occur on March 21 was back to March 11, and the perplexed farmer looked forward to eventually doing his plowing in the dead of winter.

Meanwhile, Pope Gregory XIII was looking into the problem. He set aside a room in the Tower of Four Winds in the Vatican City for research. This room is still called the Calendar Room. Here the great astronomers and ecclesiastics met with Pope Gregory to plan a revised calendar. These men had the problem of setting the clock right and of keeping it from gaining or losing, once it was set properly.

In 1582, Pope Gregory decreed that October 4 would be followed by October 15 to take up the 10-day slack. This would set the clock. To keep it running properly, he decreed that years divisible by four would be leap years with the exception of years beginning each century. These century openers would not be leap years unless divisible by 400. By this simple change, it will require 3,323 years before the error in the Gregorian Calendar will amount to a day.

This calendar perfected by Pope Gregory was adopted by Catholic countries immediately. But Protestant nations, such as Sweden, Germany and England, stuck with their Julian calendar and for nearly two hundred years, the two calendars functioned almost side by side, one eleven days behind the other.

Finally, the English Parliament decided enough was enough. It was voted to get back in step with other countries. To adjust things rapidly, it was determined to wipe out or "annihilate," as most folks of the time put it, the eleven days at one time in order for daily activity and the Gregorian calendar to jibe. Thus it was ordered that the calendar for 1752 should skip from September 2 to September 14. This caused considerable confusion in England and in lusty, growing America which was just flexing its economic muscles.

Tenants and landlords squabbled about rents, businessmen in general were upset about contract performances, delivery of goods, payment of bills

Third in a series of seven editorials on calendar history.

and other fiscal operations hinging on the calendar. Anniversaries, birthdays and weddings were all knocked askew by the sudden loss of time. The job of catching up on time in "one fell swoop" was no easy thing. It was a tremendous jolt to the life and economy of the times.

JOSEPH H. SUMMERS,
Brown & Bigelow

ALCOHOLISM IN INDUSTRY

The physician who works with persons employed in industry can do a great deal to bring about a greater understanding of the nature and extent of the alcoholism problem as it affects industry. The better job he does in educating industry, however, the greater will be his responsibility to do something about this problem. As alcoholics in industry are recognized, it will be essential that they receive adequate treatment.

Most persons concerned with the problem of alcoholism are agreed that the physician should be responsible for treatment of the alcoholic. Physicians, however, have often been reluctant to assume this additional responsibility. This is understandable. Although most physicians have accepted alcoholism as a health problem, some have resisted getting involved in the treatment of alcoholics for practical reasons. The treatment of the alcoholic is time-consuming, often discouraging, and frequently poorly rewarding.

One of the reasons that the treatment of alcoholism has been discouraging is that so many of the traditional approaches to treatment do not succeed. Because alcoholism, particularly in its latter stages, is so obvious, it seems logical that straightforward advice should be helpful. Thousands of alcoholics have been told to control their drinking. This is exactly what most alcoholics would like to do—if they could. More recently, with recognition that he cannot control his drinking, the alcoholic has often been warned that he must stop drinking completely. Advice of this kind is of little help to the addictive drinker. He knows he must stop drinking but doesn't know how.

By the time the alcoholic reaches the point where he is looking for help to overcome his drinking, he is usually tense and extremely anxious. The logical thing for the physician to do is to offer the patient some relief from his tension with sedatives.

This is exactly what the alcoholic wants. There is a real danger, however, that the dependency on alcohol or addiction to it may be transferred to another drug which, in the long run, may be more harmful. A major problem confronting institutions or agencies treating alcoholism today is those persons who have shifted their addictions to the barbiturates or have combined alcohol and barbiturates for a more potent effect.

Disulfiram, or Antabuse, has been useful in many cases. However, it must be remembered that this drug, just as the new tranquillizing drugs, does not bring about a cure. Disulfiram simply serves to help the patient resist the urge to drink. Additional help is needed to reorient his thinking; this is considered essential for continued sobriety.

The physician can provide a real service to the alcoholic by helping him to recognize his real problem. Despite what seems obvious to everyone, the alcoholic frequently is the last person to "see" his problem for what it is—a problem with alcohol. Ordinarily, he will blame his problems on his wife, family, job, children, health, financial situation, or anything but his drinking. If these other problems were cleared up, the drinking, he feels, would take care of itself. Through a discussion of the symptoms of alcoholism, the physician can often help the patient to obtain insight into his drinking problem for the first time.

Once the problem is recognized, the next step is doing something about it. This will require deep understanding, sympathy, and above all, patience. The road to alcoholism is a long one and the road back often equally long. Physicians who feel that they do not have the time to continue with the counseling and guidance so necessary for rehabilitation will find an excellent ally in AA. The men and women in AA—who have shared the experience of alcoholism—can often provide the alcoholic with insight into his problem and assist him in his efforts to maintain sobriety by the fellowship they offer. This does not mean that the physician should use AA as a place to dispose of his alcoholic patients. It means instead that the physician, while retaining medical responsibility for the case, is making use of the most effective therapeutic program for alcoholism known today.

Obviously, those patients who come to the physician in the later stages of alcoholism may not be in a position to benefit from the treatment, other than medical, he can provide. They also may not

Final editorial in a series of four on alcoholism in industry.

President's Letter

THE ANNUAL MEETING

The 104th scientific assembly and annual meeting of the Minnesota State Medical Association was held in Saint Paul on May 13, 14 and 15, 1957. Objective analysis and comments received from many who were present would indicate that the meeting was highly successful. Registration included 1,496 physicians, and in addition, some nurses, scientific and commercial exhibitors, guests and others, amounting to a total of 3,027. Comments on the scientific sessions were most favorable. The presentations of most of the speakers referred to in my April letter were discussed in glowing terms. Admiral Hyman G. Rickover's thought-provoking banquet address was accorded considerable space in newspapers which commented upon it favorably.

The House of Delegates of the Minnesota State Medical Association made commitments of great significance at this meeting. Annual dues were increased from \$40.00 a year to \$55.00. It should be pointed out that this new figure still leaves our dues well below the dues of all our neighboring state associations. Four dollars of the total of \$15.00 which constitutes the increase is earmarked for the Physicians' Assistance Fund. The other \$11.00 goes into the general fund, and this action becomes consonant with the payment of dues for 1958. The House of Delegates reiterated its request for the broadening of the corporate structure of Minnesota Medical Service (Blue Shield), requesting that all physicians who so desire be made members of the corporate body.

A new scientific committee, to be known as the Committee on Arthritis and Rheumatism, was established, and your President was asked to appoint the members of this committee, which he has done. The House of Delegates voted to sponsor the 1958 essay contest which was developed by the Association of American Physicians and Surgeons. The 1957 contest was won by Sonia Gustavson, of Olivia, who was sponsored by the Renville-Redwood County Medical Society. Her winning essay was entitled "The Advantages of Private Medical Care."

The House of Delegates voted to oppose the extension of social security coverage to physicians.

A new set of By-laws replacing the old Constitution and By-laws was adopted. These By-laws appeared in the March, 1957, issue of MINNESOTA MEDICINE. The old By-laws have been streamlined and modernized, making them consistent, as far as possible, with the By-laws of the American Medical Association. They include the creation of a Judicial Committee, the members of which will be appointed from each council or district. In the future, grievances of one kind or

PRESIDENT'S LETTER

another, whether the complaints are by physicians or laymen, will be considered by this group.

The Distinguished Service Award, presented annually to a physician who has done outstanding service to the state and to medicine, was presented to Dr. W. W. Will, of Bertha, who is also a member of the Fifty-Year Club. He celebrated his seventy-eighth birthday and his fiftieth wedding anniversary on the day this award was presented to him. Special citations for work in the field of tuberculosis went to Dr. Leo G. Rigler, of the University of Minnesota; Dr. Sidney Slater, of Worthington, Minnesota; Dr. William H. Feldman, of Rochester; and to Dr. J. Arthur Myers, of the University of Minnesota. The medal of the Southern Minnesota Medical Association, given for the best scientific exhibit, went to Dr. F. W. Hoffbauer and Dr. F. George Zaki, of the Department of Medicine, University, for their exhibit on "Experimental Fatty Cirrhosis."

Certificates for outstanding work in the field of rehabilitation of the physically handicapped went to Dr. Carl C. Chatterton and Dr. Miland E. Knapp, and were presented by Governor Orville L. Freeman at the annual banquet of the Minnesota State Medical Association on Tuesday evening.

A very successful golf tournament and a successful trap and skeet shoot were held. Names of the winners of these events appear in this issue of MINNESOTA MEDICINE.

The open house on Monday evening and the banquet on Tuesday could well be rated as impressive successes. As always, great credit goes to Mr. R. R. Rosell and his staff for the conduct of the very successful meeting and the clocklike precision with which the entire meeting was carried out.

As successful as the meeting was, a sense of disappointment nevertheless must have entered the minds of the speakers at the scientific assembly as they viewed the scanty attendance on the part of physicians at the lectures, symposia and panels conducted in a large measure by national and international authorities on their subjects. Considering the achievements and reputations of the men on the platform, it was reasonable to hope that a large number of physicians would come to listen to them. Unfortunately, this did not prove to be so. Your President would be greatly pleased to have any suggestions for the improvement of attendance at the scientific session of our Association.

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is written in a cursive style with a large, sweeping loop at the beginning.

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

SERIES OF IMPORTANT RESOLUTIONS PASSED AT ANNUAL MSMA MEETING

Registration at the 104th annual meeting of the Minnesota State Medical Association held in St. Paul May 13, 14 and 15 passed the 3,000 mark with 1,496 physicians, 156 nurses, dietitians and individuals in related fields, 113 scientific exhibitors, 517 commercial exhibitors, 241 members of the woman's auxiliary and 504 miscellaneous guests in attendance. A series of important resolutions was passed by the House of Delegates in its two-day session:

\$15 Increase in Dues

The House voted a \$15 increase in state association dues, from \$40 to \$55 annually. Four dollars of this total is earmarked for the physicians' assistance fund which was about depleted. The additional \$11 goes into the general fund. This dues increase becomes effective in 1958.

Blue Shield

The House of Delegates also renewed its drive for greater physician participation in Blue Shield. A resolution was passed asking that the corporate structure of Blue Shield be broadened to include all participating physicians who desire membership.

New Committee

The House voted to establish a new committee on Arthritis and Rheumatism, the members of which would be appointed by the President of the Association. These appointments have been made.

Social Security

The House resolved to firmly oppose any legislation which would extend social security coverage to members of the medical profession.

Health Insurance Programs

The House also went on record to aid in developing state and federal laws regulating private health insurance programs to prevent unjust rates and practices.

Constitution and By-laws

The House adopted a new set of By-laws replacing the old Constitution and By-laws of the Association. The proposed new By-laws appeared in the March, 1957, issue of MINNESOTA MEDICINE. This recent revision afforded the opportunity to streamline and modernize the old By-laws and make them consistent, as far as possible, with the Constitution and By-laws of the American Medical Association.

Essay Contest

The House voted to sponsor the 1958 essay contest sponsored by the Association of American Physicians and Surgeons. The 1957 contest was won by 18-year-old Sonia Gustavson from Olivia, Minnesota. Her entry was sponsored by the Renville-Redwood County Medical Society with Dr. J. A. Cosgriff, Olivia, in charge. Miss Gustavson's topic was "The Advantages of Private Medical Care."

AMA HOUSE OF DELEGATES ACTS UPON WIDE VARIETY OF SUBJECTS

Revision of the Principles of Medical Ethics, relations with the United Mine Workers of America Welfare and Retirement Fund, the Medicare program, new standards for medical schools, occupational health programs and social security benefits for physicians were among the wide variety of subjects acted upon by the House of Delegates at the American Medical Association's 106th annual meeting held June 3-7 in New York City.

A complete report of the actions of the House will appear in the August issue of MINNESOTA MEDICINE. A brief summary follows:

Principles of Medical Ethics

The House approved the long-discussed revision of the Principles of Medical Ethics submitted at the 1956 annual meeting in Chicago. In approving the new Principles, the House also reaffirmed the "Guides for Conduct for Physicians in Relationships with Institutions," adopted in 1951 and requested the Board of Trustees to devise and ini-

tiate a campaign to educate both physicians and the general public to the dangers inherent in the illegal corporate practice of medicine in its various forms.

Guides for Relations with the UMWA Fund

The AMA House of Delegates also adopted the "Suggested Guides to Relationships Between State and County Medical Societies and the United Mine Workers of America Welfare and Retirement Fund" which were submitted by the AMA Committee on Medical Care for Industrial Workers. In approving the guides, the House also recommended that the Board of Trustees study the feasibility and possibility of setting up similar guides for relations with other third-party groups such as management and labor union plans.

Medicare

The House considered three resolutions dealing with the federal government's Medicare program for the dependents of servicemen. The delegates adopted one resolution condemning any payments under the Medicare program "to or on behalf of any resident, fellow, intern or other house officer in similar status who is participating in a training program." In a second action, the House recommended that the decision on type of contract and whether or not a fee schedule is included in future contract negotiations should be left to individual state determination.

The House also suggested that the AMA attempt to have existing Medicare regulations amended to incorporate the Association's policy that the practice of anesthesiology, pathology, radiology and physical medicine constitute the practice of medicine and that fees for services by physicians in these specialties should be paid to the physician rendering the service.

Medical Schools

To replace the "Essentials of an Acceptable Medical School," initially approved by the House of Delegates in 1910 and most recently revised in 1951, the House adopted a new statement entitled "Functions and Structure of a Modern Medical School." Presentation of the document followed a year of careful study by the Council on Medical Education and Hospitals in collaboration with the Association of American Medical Colleges.

Occupational Health Programs

The House also approved a new statement on the "Scope, Objectives and Functions of Occupational Health Programs" submitted through the Board of Trustees by the Council on Industrial Health. The statement describes and defines orthodox in-plant medical programs as understood in this country today and distinguishes clearly between such programs and the various plans for comprehensive medical care of the sick.

Social Security for Physicians

The House of Delegates reaffirmed their opposition to compulsory coverage of physicians under the Old Age Survivors Insurance provisions of the Social Security Act. They also recommended a strongly stepped-up information program of education which would reach every member of the Association explaining the reasons underlying the position of the House of Delegates on this issue. The House also reaffirmed its support of the Jenkins-Keogh bills.

Election of Officers

Dr. Gunnar Gundersen of La Crosse, Wis., member of the AMA Board of Trustees since 1948 and chairman for the past two years, was unanimously chosen president-elect. He will succeed Dr. David B. Allman of Atlantic City, N. J., who became the 111th president Tuesday, June 4, at the inaugural ceremony in the Grand Ballroom of the Waldorf-Astoria Hotel.

Other officers are: Dr. Jesse Hamer, Phoenix, Ariz., vice president; Dr. George F. Lull, Chicago, secretary; Dr. J. J. Moore, Chicago, treasurer; Dr. E. Vincent Askey, Los Angeles, speaker; Dr. Louis Orr, Orlander, Fla., vice speaker.

The four new members elected to the Board of Trustees include Dr. George Fister, Ogden, Utah; Dr. Cleon Nafe, Indianapolis; Dr. James Z. Appel, Lancaster, Pa., and Dr. Raymond McKeown, Coos Bay, Oregon.

LITTLE HEALTH LEGISLATION ACTIVITY ON CAPITOL HILL

With budget-cutting continuing to keep Congress occupied, bills calling for new Federal spending are keeping their positions on committee shelves. However, the past few weeks have seen some moves of great interest to physicians:

Doctor-Draft Bill

Late in May the House Rules Committee gave the go-ahead signal for floor consideration of the unopposed legislative substitute for the doctor-draft law which expired June 30.

Jenkins-Keogh Retirement Program

Members of the House and Senate received thousands of messages from physicians last month urging enactment of the Jenkins-Keogh retirement legislation. This legislation would (a) allow the self-employed to put up to 10 per cent of their income per year (maximum of \$5,000) into restricted annuity programs or insurance without paying income tax on the amount, (b) receive the money back in the form of pension payments, generally after age sixty-five, and at that time pay income tax on it. Employees of corporations now have the same tax advantage, and (c) impose a tax penalty if the money were withdrawn from the fund prior to the stated retirement age.

Seven associations, including the AMA, have now banded together into a national organization to promote this legislation. The name of the new organization is "American Thrift Assembly for Ten Million Self-Employed." In addition to the AMA, charter members of the new group are the American Bar Association, the American Institute of Accountants, the American Retail Federation, the National Association of Real Estate Boards, the American Dental Association and the National Association of Retail Druggists.

U. S. GP'S SUPPORT BRITISH COLLEAGUES

The American Academy of General Practice recently issued a statement lining their members up solidly behind their British colleagues who are caught between spiraling costs and the Ministry of Health's refusal to grant a promised salary increase. Pointing out that the British medical care plan "has failed miserably and put medicine on a mass production basis," the AAGP urged British family doctors and specialists to resign from the NHS.

U. S. CONTRIBUTION TO WHO BUDGET DROPS

Because Russia and three satellite countries are returning to active participation in the financing of the World Health Organization, the U. S. contribution for the current year will drop to one-third, for the first time since WHO was organized.

AMA PROTESTS PRESIDENT'S BUDGET

Representatives of more than thirty of the nation's largest trade associations, including the AMA, attended an all-day "action conference" in Chicago recently to protest the President's \$71.8 billion budget. The 250 business and professional men were in complete agreement on the salient point that the federal budget can and must be cut.

SURVEY CONDUCTED ON DOCTORS' DUES

A recent survey conducted on dues levied by local and state medical societies as well as by the AMA included a study of how these dues compare with a dozen different professions or trades in a dozen different cities.

In general, the survey revealed that doctors' dues ran higher than most other groups—but not much higher. In a few places, they run lower. Some sample findings are these:

Doctors' dues average about \$100 in the cities surveyed—that is the average of their *total* dues to local, state and national medical societies. The comparable figure for airline pilots is over \$200; for architects, about \$90; for accountants, \$70; for lawyers, \$60, and for steel workers, \$60.

In Baltimore, the doctors pay a total of \$70 in annual dues, but the architects pay \$77.50; in Chicago, the doctors pay \$80, but the lawyers pay \$117; in Newark, the doctors pay \$75, but the architects pay \$95; the bricklayers, \$100. In New York, the doctors pay \$75, in dues; the accountants, \$80; the architects, \$85, and the lawyers, \$106.

BLUE CROSS ISSUES ANNUAL REPORT

Last year, members of Blue Cross received more than \$1 billion worth of hospital care, the largest yearly amount ever paid in the history of hospital prepayment. Blue Cross disclosed these figures in its financial report for 1956. The report showed that 92.7 cents of each subscriber's dollar were returned in the form of hospital service benefits; 6.2 cents per dollar were allocated to Plan operating expenses and the remaining funds were added to Plan reserves.

Nine million Blue Cross members admitted to hospitals last year received more than 53 million patient days of care through the various Plans. Out-patient care is included in these figures. The average hospital stay for a Blue Cross member in 1956 was 7.5 days.

OSTEOPATH, NATUROPATH BILLS PASSED IN UTAH

Two bills permitting naturopaths to perform minor surgery, obstetrical work and prescribe drugs passed the Utah state senate and house and at last report were awaiting the governor's signature.

Other measures passed include a bill permitting hospital staff appointments of osteopaths and the establishment of osteopathic hospitals.

DISABLED "OVER FIFTY" START DRAWING MONTHLY BENEFITS

Men and women workers who have earned at least five years of credit under the federal social security program, are past fifty, and are presumed to be totally and permanently disabled with regard to gainful employment started drawing monthly benefits July 1. Under the definition of the social security law, disability implies that a person must be unable to "do any substantial work, and the disability must be one that is expected to continue indefinitely."

MEDICAL QUACKERY IN MAILS REACHES NEW HIGH

Use of the mails to promote medical quackery is at the highest level in history, Postmaster General Arthur E. Summerfield said recently. The report said that medical frauds today are more lucrative than any other criminal activity and that medical fraud cases now pending represent an annual loss to the public of \$50 million.

Medical frauds most common, in order of popularity, are "dietless" reducing schemes and "sure cures" for cancer, arthritis, skin trouble, baldness and "lost manhood." Mr. Summerfield urged citizens to report suspected mail frauds to the post-office department for prompt investigation.

INJURIES OF THE EXTERNAL GENITALIA

(Continued from Page 504)

as to frequency varying from "never" to "common." Most cases of epididymitis or "strain" are associated with prostatitis and not related to industry. However, there are some instances of undoubted correlation. The common situation involves two men lifting or carrying a heavy object. One man loses his grip and the weight is sud-

denly thrust upon the other, who experiences almost immediate inguinal or scrotal pain. Several hours later swelling and recurrence of pain and rather typical epididymitis appear. The mechanism is reflux of urine and/or prostatic secretion down the vas.

Torsion of the cord is rarely a traumatic lesion in the usual sense. Suffice it to say, this is a strict emergency and any salvage must be accomplished in less than three hours.

CASE STUDIES, MINNEAPOLIS VETERANS HOSPITAL

Eosinophilic Granuloma

(Continued from Page 507)

source for metastatic disease, the patient was presented to the tumor conference, and a decision to remove the area "en bloc" was made. The surgery was performed, removing the ninth rib together with a part of the eighth and tenth ribs and the intervening intercostal muscles. The pathological examination of this tissue showed dense sheets of mature and immature eosinophils associated with numerous nonlipid histiocytes. The diagnosis of this tumor was eosinophilic granuloma. The patient recovered uneventfully from the surgery and at the present time is free of symptoms.

Discussion.—This patient has an eosinophilic granuloma in one of the common sites for this type of lesion, namely, the ribs. Other bones that are commonly involved are the bones of the cranial vault, the vertebrae, and particularly the humerus and the femur. This type of eosinophilic granuloma represents the mildest manifestation of a group of diseases that probably are all basically the same. The other two components of this triad are, Letterer-Siwe disease (which occurs predominantly in younger children under the age of two years) and Hand-Schüller-Christian disease (which frequently involves multiple bones at a given time). The Letterer-Siwe disease is usually associated with skin manifestations and visceral involvement, and the disease is 100 per cent fatal. Hand-Schüller-Christian disease does not involve skin but it occasionally affects the pituitary gland, causing diabetes insipidus. The latter disease may cause exophthalmos, and lesions in the lung are often seen. This disease also may lead to death.

The prognosis, however, for a simple eosinophilic granuloma of the bone in a patient of the age in this case report, is good. These lesions are radiosensitive and can be treated and cured with small amounts of irradiation. On occasion, recurrences after surgery have disappeared with properly applied irradiation therapy. In the present instance, the choice of total removal of this primary and localized tumor was wise, but in the event that extension of the disease had occurred and it manifests itself later in surrounding tissues, deep roentgen irradiation would be the therapy of choice.

Minnesota State Medical Association

Highlights of the 104th Annual Meeting

NEW OFFICERS ELECTED

Dr. H. B. Sweetser, Minneapolis, was named president-elect of the Minnesota State Medical Association during the 104th annual meeting of the group in St. Paul in May. He will take office January 1, 1958. A native of Minneapolis and a specialist in internal medicine, Dr. Sweetser graduated from Harvard Medical School. He is the son of the late Dr. H. B. Sweetser of Minneapolis. His mother was one of the founders and the first president of the state Woman's Auxiliary.

Dr. Sweetser has served for five years as counselor from the sixth district. He will be succeeded by Dr. Donald McCarthy of Minneapolis. Dr. McCarthy is former treasurer of the Association and will be succeeded by Dr. Karl Anderson, Minneapolis.

Other new officers, all to take office January 1, include Dr. T. R. Fritsche, New Ulm, first vice president; Dr. Wallace P. Ritchie, St. Paul, second vice president, and Dr. R. P. Buckley, Duluth, vice speaker of the House of Delegates.

Dr. B. B. Souster, St. Paul, was re-elected secretary; Dr. H. M. Carryer, Rochester, former vice speaker, was named speaker of the House of Delegates. Dr. C. G. Sheppard, Hutchinson, fourth district, and Dr. J. P. Medelman, St. Paul, fifth district, who had been appointed to the Council to replace Drs. H. J. Nilson, Mankato, and L. R. Critchfield, St. Paul (deceased), were officially elected councilors for their respective districts. Dr. C. L. Oppegaard, Crookston, was re-elected to succeed himself as eighth district councilor. Dr. Oppegaard is also chairman of the Council.

Re-elected delegates to the AMA are Drs. George Earl, St. Paul, and O. J. Campbell, Minneapolis. Re-elected alternates are Drs. E. M. Hammes, St. Paul, and C. L. Oppegaard, Crookston.

SOUTHERN MINNESOTA MEDAL RECIPIENTS

Dr. F. W. Hoffbauer and Dr. F. George Zaki of the Department of Medicine at the University of Minnesota received the medal given by the Southern Minnesota Medical Association each year for the best scientific exhibit at the annual meeting. Dr. Charles Strobel, Rochester, president of the Association, made the presentation at the annual banquet of the Minnesota State Medical Association, Tuesday, May 14.

The award-winning exhibit concerned "Experimental Fatty Cirrhosis."

DISTINGUISHED SERVICE AWARD

Dr. W. W. Will, Bertha, received the distinguished service award presented by the Minnesota State Medical Association at the annual banquet of the group at the Hotel Saint Paul, May 14.

Dr. Will became a member of the Council in 1927, served as president of the Association in 1936, was speaker of the House of Delegates from 1938 to 1946, has served as an alternate delegate to the American Medical Association and has held various important committee appointments.

In 1948, he was named the "outstanding general practitioner in Minnesota."

Dr. Will also joined the "Fifty Club" group this year. The day he received these honors (May 14) was his seventy-eighth birthday and his fiftieth wedding anniversary.

SPECIAL CITATIONS

Four Minnesota men were honored for their work and research in the field of tuberculosis at the annual banquet of the Minnesota State Medical Association, May 14.

Each received a special citation presented by Dr. C. L. Oppegaard, Crookston, chairman of the Council.

These men include Dr. Leo G. Rigler, formerly head of the Department of Radiology at the University of Minnesota, now in Los Angeles; Dr. J. Arthur Myers, who has just retired from his post at the University of Minnesota and who initiated the county accreditation program for the control of human tuberculosis; Dr. William Feldman, Rochester, who was cited for his work in the development of basic medical knowledge of the antibiotics, and Dr. Sidney Slater, Worthington, superintendent of the Southwestern Minnesota Tuberculosis Sanatorium for thirty-eight years and the man who initiated the routine use of the Mantoux tuberculin skin test in the schools of his district.

GOVERNOR PRESENTS TWO SPECIAL AWARDS

Governor Orville Freeman presented two special awards at the annual banquet, May 14, both to physicians who have contributed much in the field of physical medicine and who have worked for many years to rehabilitate handicapped individuals. The two Minnesotans honored were Dr. Miland E. Knapp, Minneapolis, and Dr. Carl C. Chatterton, St. Paul. Dr. Knapp was saluted

for his many years of service to the Kenny Institute and Dr. Chatterton, for his long-time service as chief of staff of the Gillette State Hospital for Crippled Children.

DOCTOR ADCOCK ADDRESSES WOMEN PHYSICIANS

Dr. Madeline Adcock, Glencoe, Minnesota, was the chief speaker at the luncheon held by the American Medical Women's Association, Inc., Minnesota Branch No. 26, May 13, at the St. Paul Athletic Club.

Dr. Adcock spoke of the four years she and her husband spent in a bush village 250 miles inland from the ocean in Ghana, Africa.

Dr. Helen Knudsen of the Minnesota Department of Health received honorable mention at the luncheon. She was named "Woman Doctor of the Year" last year.

WINNERS OF SPORTS EVENTS

Skeet and Trap

Dr. Harold R. Tregilgas, South St. Paul, chairman of the skeet and trap shooting events held in conjunction with the 104th annual meeting, Sunday, May 12, announces the winners of the various shooting events and their prizes, as follows:

In the skeet category, Dr. Earl Barrett of Duluth won the first place cup presented annually; Dr. Tregilgas took second place, receiving a shell box donated by the Gokey Company, St. Paul. Their scores were 45 and 44, respectively. Dr. Richard Tucker, Minneapolis, won third prize with a score of 44. He received a Cary thermometer presented by the U. S. Vitamin Corporation.

For fourth place in skeet with a score of 44, Dr. Malcolm Pearson, St. Paul, won a \$10.00 merchandise bond from Roy Novotny Sporting Goods, St. Paul. Dr. Baxter A. Smith, Jr., Minneapolis, won a pair of sunglasses donated by Northwest Opticians, St. Paul, as fifth place winner with a score of 43. Dr. Joseph Bicek, St. Paul, received the low net prize which was a set of golf balls contributed by the Skeet and Trap Committee.

In the trap event, Dr. Albert C. Kelly received the first prize cup for the second year with a score of 42. Dr. Malcolm Pearson took second place and received a \$10.00 gift bond from V. Mueller and Company. Dr. William H. A. Watson, St. Paul, took third place with a score of 42; his prize was a watch band contributed by the Desitin Chemical Company. Fourth place winner was Dr. Earl V. Wetzel, St. Paul, who scored 41; Dr. Wetzel received a razor from the Hall, Anderson, Nordine Pharmacy, St. Paul. Dr. Tregilgas placed fifth and received a mechanical pencil contributed by Ciba Pharmaceutical Products, Inc.

Dr. Malcom Pearson received his third prize of the day as first place winner in the razzle-dazzle

skeet shoot. He was presented with a cup for his score of 21. Dr. Baxter Smith, Jr., took second place and received a Howe table contributed by Brown and Day, Inc. Dr. Robert Tenner, Minneapolis, scored 17 and received a prize donated by Moudry's Apothecary Shop, St. Paul. Dr. Tregilgas took fourth place and received a barbecue gong from Rowell Laboratories. Dr. Richard Tucker placed fifth with a 16 score and received a razor from Hall, Anderson and Nordine Pharmacy.

Members of Dr. Tregilgas' committee for the shooting events were Drs. L. J. Michienzi, N. M. Palm and E. A. Smisek, St. Paul.

Golf

Winners of the annual all-physician golf tournament held Sunday, May 12, at the White Bear Yacht Club, Dellwood, have been announced by golf chairman, Dr. B. G. Lannin, St. Paul.

Taking first place in the low gross category was Dr. Philip A. Olson, Minneapolis, with a score of 73. Dr. Olson won an electric frying pan contributed by the St. Paul Fire and Marine Insurance Company. Dr. Wallace J. Olson, Minneapolis, was second place winner, also with a score of 73. His prize was a carving set presented by Smith, Kline and French Laboratories. Dr. S. H. Calin, who placed third with a score of 76, received a set of golf balls from Hoffmann-La Roche, Inc. Dr. Lannin, fourth place winner with a score of 78, received a dictionary contributed by the W. B. Saunders Company. Dr. L. C. Lick, St. Paul, received a set of golf club covers from Ortho Pharmaceutical Company as fifth place winner.

Dr. J. A. Nesse, Austin, who took first place in the low net category, received a lazy Susan contributed by Eli Lilly and Company. Dr. E. M. James, St. Paul, second place winner, won a waste basket from Brown and Day, Inc. Third place winner, Dr. D. H. Correa, Minneapolis, received golf balls from Hoffmann-La Roche, Inc. Dr. P. C. Leck, Austin, came in fourth and won a pillow donated by C. F. Anderson Company, Inc. Fifth place winner, Dr. C. O. Erickson, Minneapolis, received a timer from General Electric.

Drs. V. P. Hauser, St. Paul; John Dordal, Sacred Heart; E. C. Burseth, Mora; C. L. Lick, St. Paul, and H. H. Noran, Minneapolis, were winners in the blind bogey event. Their prizes, respectively, were a billfold from Ulmer Pharmaceutical Company, a barbecue gong from Rowell Laboratories, a watchband from Desitin Chemical Company, a mechanical pencil from Ciba Pharmaceutical Products and a phone directory from Physicians and Hospitals Supply Company.

Door prizes were contributed by Holland-Rantos Company, Inc., and Merck Sharp and Dohme.

Members of Dr. Lannin's golf committee were Drs. S. H. Calin, E. C. Gibbs, V. P. Hauser, T. W. O'Kane, W. J. Paulson and E. L. Strem, St. Paul.

ART AND HOBBY SHOW WINNERS

Winners in the art and hobby show presented during the 104th annual meeting in St. Paul have been announced by Dr. Vernon D. E. Smith, St. Paul, chairman of the event.

In the oil paintings division, Dr. Carl O. Rice, Minneapolis, took first place with his "North Shore Scene"; Dr. Byron Armstrong, Hopkins, took second place with his "Autumn Scene." Receiving honorable mention were Dr. D. A. Limbeck, Le Sueur, for "Melancholy Clown" and Dr. Paul Brabec, Hastings, for "Portrait of an Old Man" and "Portrait of an Old Woman."

Dr. James L. Benepe, St. Paul, took first place in the watercolor division with his "Fall Field"; Dr. Donald B. Swenson, St. Paul, took second place for his "Skyline" painting.

Taking first place for the best "single exhibit" in the watercolor division was Dr. John Coe, Minneapolis, for his "Impressions of the City."

Dr. James H. Crowley, St. Paul, took first place in the sculpture division.

In the "hobbies" section, Dr. Arthur W. Garbrecht, Minneapolis, took first place for his collection of gold and silver coins. Dr. F. A. Zinter, Minneapolis, placed first in the handicrafts division for his silversmithing and hand-made jewelry. Dr. Henry H. Michel, Minneapolis, took second place in this division with his model locomotive. In the photographic prints division, Dr. F. H. Walter, International Falls, took first place with his "Depot Scene."

In the "inventions" category, Dr. John Wild, of Minneapolis, took first place with his steam out-board motor exhibit.

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building, Saint Paul 1, Minnesota

F. H. Magney, M.D., Secretary

PHYSICIAN'S LICENSE SUSPENDED FOR THREE YEARS

On May 25, 1957, the Minnesota State Board of Medical Examiners suspended for a period of three years the medical license held by Nicholas G. Boosalis, M.D., because of his personal use of narcotic drugs. Dr. Boosalis had previously appeared before the Board on February 10, 1956, for similar misconduct, at which time he was permitted to retain his medical license by entering into a stipulation with the Board, in which he agreed to the surrender of his narcotic privileges until the further order of the Board and also to refrain from the personal use of narcotic drugs. Dr. Boosalis at that time had completed a period of hospitalization for the treatment of his illness and was on the medical staff of a United States Veterans Hospital outside the State of Minnesota. However, it subsequently came to the attention of the Minnesota State Board of Medical Examiners that Dr. Boosalis had violated the terms of the stipulation by indulging in the personal use of demerol, which he obtained from the drug supply of the hospital where he was employed.

Dr. Boosalis was born in Faribault, Minnesota, in 1915 and received an M.D. degree from the University of Minnesota in 1941. After serving his internship in Duluth, Dr. Boosalis was licensed by examination to practice medicine in Minnesota in February, 1941. After serving in the United States Army, Dr. Boosalis engaged in the private practice of medicine for more than a year in Colorado and also served as a staff physician at Veterans Hospitals in several states.

PHYSICIAN'S LICENSE REVOKED

On May 25, 1957, the Minnesota State Board of Medical Examiners revoked the license to practice medicine and surgery held by Philip C. Welton, M.D. because of his habitual indulgence in the excessive use of alcoholic liquors and his numerous court convictions for drunkenness. Dr. Welton, who is forty-eight years of age, formerly engaged in the practice of medicine in Minne-

sota, but since 1950 he has practiced in Wisconsin, his present address being 517 W. Wells Street, Milwaukee, Wisconsin. Dr. Welton had not paid his annual registration fee to the Minnesota State Board of Medical Examiners since 1952, and when he made inquiry in regard to the amount of the arrearage, the Board discovered that Dr. Welton had a number of court convictions in Milwaukee, Wisconsin, for drunkenness and that he had agreed to the voluntary surrender of his Wisconsin medical license as a result of his conduct. A citation was therefore issued by the Board on March 9, 1957, requiring Dr. Welton to show why his license should not be revoked. Although Dr. Welton received a copy of the citation, he did not appear at the hearing before the Board on May 24.

Dr. Welton's medical license was previously suspended by the Minnesota State Board of Medical Examiners on December 29, 1949, due to his failure to appear in response to a citation in which he was charged with having been committed to the Rochester State Hospital as mentally ill on June 24, 1949, and with habitually indulging in the excessive use of alcoholic liquors and barbiturate drugs. The Board ordered that Dr. Welton's license be suspended until he made a personal appearance in response to the citation. On February 10, 1950, Dr. Welton appeared before the Board and indicated that he had taken steps to rehabilitate himself and that he desired to obtain licensure in Wisconsin to enable him to be employed as a staff physician at a sanatorium there. After it was ascertained that Dr. Welton had been restored to legal capacity by the Probate Court of Wabasha County on October 10, 1949, and that he was willing to enter into a stipulation with the Board in reference to his future conduct, the Board terminated the suspension of Dr. Welton's license.

Dr. Welton was born in Pewaukee, Wisconsin, on May 8, 1909. He received an M.D. degree from Marquette University in June, 1937, and was licensed in Minnesota by examination in the same month. In addition to practicing medicine in Wisconsin Dr. Welton has practiced in Utah and Arizona and has also served as a staff physician in sanatoriums in Nopeming and Wabasha, Minnesota.

History of Medicine in Minnesota

THE HISTORY OF MEDICINE IN POLK COUNTY

J. F. NORMAN, M.D.
Crookston, Minnesota

(Conclusion)

Julien F. Gendron was born at St. Francis in Montmagny, Province of Quebec, Canada, on March 31, 1868. He died September 11, 1947. He was well known in Canadian literary circles as a poet, doing his writing in French. He once was Poet Laureate of Canada. He studied law at Laval University, graduated from the University of Quebec, and later, studied at Hamline University in St. Paul, where he received his medical degree in 1896. Dr. Gendron practiced for a time at Centerville, Crookston, and Red Lake Falls, and in 1900 began practice in Grand Rapids where he served as Health Officer and Examiner for the American Veterans Bureau. He served as Captain in the American Army Medical Corps in World War I. He was a member of the Range Medical Society, Medical Staff of Itasca County Hospital at Grand Rapids, a member of the St. Louis County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also licensed in California and took postgraduate work at the Chicago Polyclinic, Tulane University and Mayo Clinic at Rochester.

He was a member of the Society of French Canadian Poets, several works in verse were never published but his greatest epic was "La Legende des Chevalier d'Oil" (1928). It was heralded as the first epic in French since Voltaire. His second was "La Laurentiade," which was a story of the siege of Quebec. The *St. Louis County Bulletin* of October, 1947, summed up in Dr. Gendron's obituary with the statement: "A gentleman and a scholar has passed on." He was survived by his widow and a son, Bertrand, who is a druggist in Brainerd, Minnesota.

Herbert H. Hodgson was born June 13, 1870 at Kleenburg, Ontario, and was naturalized in 1900. He had preliminary education at Walkerton, Ontario, High School and attended college at Toronto, when he was graduated in 1894. He was graduated in medicine from the Trinity Medical College in Toronto in 1898 and was licensed that year. He first located at Fisher in the 1890's. He later moved to Crookston and married Adelaide Marin in July, 1899. He was associated with the Crookston Clinic but retired from active practice in 1941 because of coronary obstruction. He was a member of the Red River Valley Medical Society, the State Medical Association, American Medical Association and of the Masonic Blue Lodge No. 141. He was an active member of the staffs of both Crookston hospitals. Dr. Hodgson had a large practice, both hospital and general, with some country work. In his early residence in Crookston, before cars were in general use, he made his calls with a buggy drawn by a beautiful bay horse. He was an examiner in Local Board No. 2, Polk County, and was a county physician and city physician. He practiced in Polk County for more than forty years. During that time he took a number of postgraduate courses in medicine and surgery. He died July 3, 1949, while visiting his daughter, Dr. Jane Hodgson (Quattlebaum) of St. Paul. A second daughter, Mrs. Kathryn Stocklan, lives in Chicago. He made his home at

231 Washington Avenue, Crookston, where Mrs. Hodgson still resides. He was affiliated with the Methodist Church, his father, John Hodgson, having been a Methodist Episcopal clergyman. Dr. Hodgson was an ardent sportsman, going out hunting every fall for deer and spending considerable time fishing in season. He had a summer home at Union Lake.

Halvor Holte was born near Stavanger, Norway, July 11, 1857. He came to America with his parents in 1872 at the age of fifteen. He graduated from the University of Minnesota in 1893 and was licensed in 1895. He started to practice in Crookston and continued there until his death. He attended St. Olaf Academy and St. Olaf College and did postgraduate work in Berlin, Germany, in 1905. He practiced for a while in partnership with Dr. O. L. Bertleson of Crookston. Church affiliation was with United Lutheran Church, English Lutheran Church. He was a member of Sons of Norway and Scandinavian American Fraternity. Dr. Holte was a staff member of Bethesda and St. Vincent Hospitals, Crookston. He was also active in the Red River Valley Medical Society (past secretary), Minnesota State Medical Association and American Medical Association, as well as the Citizens League of Polk County (past president). He helped establish Bethesda Hospital in 1897 and launched the movement for the creation of Sunnyrest Sanatorium at Crookston. He also was director of the Crookston Association of Public Affairs and was on the board of the local banks. In business circles, he was a director of the Scandia-American Bank of Crookston and of the Crookston Commercial Club. He was past president of the Norman County Tuberculosis Sanatorium commission, a member of the American Public Health Association, director of the Minnesota Public Health Association, and a fellow of the American College of Surgeons (1920). He practiced as late as December 30, 1936. He died January 2, 1937, at Bethesda Hospital in Crookston at the age of seventy-nine. He was the first homesteader at Holt, Minnesota, which was named for him. His wife, the former Henriette Lunde of Maplebay, survived him and at present lives in Crookston (1953).

C. P. Johnson was listed in Crookston in 1890. Nothing is known of him.

Syvart H. Johnson practiced in Climax in 1898. He is listed there in 1903 and 1905. In 1909, he is listed in Bellingham, Washington. He graduated from Jefferson Medical College, Philadelphia, in 1897 and was licensed in the same year, June 10, 1897 (License No. 812). He died in Bellingham, June 20, 1942, from cerebral thrombosis at the age of seventy-two.

August (Adolph) Just, a homeopath, was practicing in Crookston in 1886. He was born in Dodge County, Wisconsin, on November 23, 1851. He was rich in well-merited affection and respect of the people of Crookston, his fellow citizens. In 1881, he graduated from Hahnemann Medical College and Hospital, Chicago, and settled in Crookston the following year. He built a comfortable practice and was a very good ether anesthetist, helping the surgeons of the city. He was a member of the Congregational Church in Crookston. He died suddenly in 1923. He had gone up to his office in the evening, and stepped out to an adjoining office, where he dropped to the floor unconscious and died almost immediately. When found, the lights in his office were still burning, and on his desk was a volume on medicine open at an article on heart diseases.

George Paul Kirk started his practice of medicine in 1896 in East Grand Forks where he still lives (1954). He was born June 8, 1875, in St. Paul and attended the Medical School of the University of Minnesota, where he graduated in 1895.

He had a one-year internship at the City and County Hospital in St. Paul and started to practice in East Grand Forks in 1896. In about 1897, he married Anna M. Schilling of Hastings. They have three children: Cyrus, who is in agricultural work in Canada; Paul, who played good football for Minnesota about 1940; and Dorothy, who is married and lives in Fargo, North Dakota. Dr. Kirk was health officer of East Grand Forks and was on the staff of St. Michael's and Deaconess Hospitals. He is a member of the Red River Valley Medical Society and the Minnesota State Medical Association.

Frank H. Knickerbocker was registered in Crookston and in Fertile. He graduated from the Detroit Medical College, Detroit, Michigan, in 1879 and was licensed in 1889 (Certificate No. 44-B). The record of births and deaths at the city of Henderson, Sibley County, Minnesota, show that he was in Henderson, February 10, 1893, and was still there until March 10, 1899. The people there who knew him stated that he was a tall, fine looking gentleman, who took an active part in civic affairs, gave much attention to the public schools, and was on the local school board. He is remembered by a former country boy, to whom he gave a lift on a dusty road. He is remembered also for his kindly interest in this boy, the boy's schooling and other problems. He was married and had two children, and settled at Anoka. Later he went to Staples, where he continued to live during the early 1920's. He died November 17, 1923. He was a member of the Upper Mississippi Medical Society and the State Medical Association.

Howard Lancaster apparently practiced in Fisher as early as 1890, and is listed there in Polk's Medical Directory as late as 1896, though other directories list him there in 1898. He was born in England about 1846 and came to the United States in 1887. He started to practice in Grand Forks, North Dakota, and was licensed in Minnesota by exemption on December 31, 1883 (License No. 590-1). Between 1898 and 1903, he was in St. Paul where he served as City Health Commissioner from 1910 to 1914. During the influenza epidemic in 1918, he volunteered his services to the government in October of that year, although he was seventy-two years old. Dr. Lancaster retired in 1919 and went to Louisville, Kentucky, to live with his son. While on the way to visit his daughter in Milwaukee, he became seriously ill and died in Milwaukee on July 30, 1920. He was survived by his widow, two sons, and a daughter. He was a genial and highly respected physician, known to everyone by his long, flowing white beard.

John Felix Landry settled in Crookston about 1886 and in Gentilly briefly in 1890. He was born at Carleton, Province of Quebec, Canada, on January 31, 1856. He graduated from Laval University, Canada, in 1880. His Minnesota license was issued April 22, 1884, by diploma (No. 881). In 1890, 1895, and 1898, he was listed in Duluth, in 1903 and 1905 without an address, and in 1909 in Osseo, Hennepin County. Dr. Landry retired in 1928 after having practiced fifty-three years. He died February 4, 1938, in Minneapolis from coronary sclerosis at the age of eighty-two and was buried in St. Mary's Cemetery in Minneapolis. He was survived by four daughters: Mrs. Leontine Sherlock, St. Paul; Mrs. F. R. Horeish, St. Paul; Mrs. Fred B. Peterson, Minneapolis; and Mrs. William Ryan, Seattle; and by two sons: J. Robert Landry, Minneapolis, president of the Landry Transfer Company, and Arthur Landry. His wife, Rose Ann Landry, preceded him in death.

Israel Lemieux was born in St. Urban, Chateaugnay, Quebec, April 9, 1852. He had a good classical education and graduated from Bishop's Medical College,

Montreal, in 1874. After practicing for several years in Canada, he came to Minnesota in 1880. He probably was in Fertile before settling in Red Lake Falls about 1883. Two years later he moved to St. Louis, Mississippi, but returned to Red Lake Falls after about two years because his wife's health could not tolerate the climate in Mississippi. He was licensed in Minnesota in 1883 and in Mississippi in 1885. In Red Lake Falls Dr. Lemieux was greatly interested in civic and church affairs; he was president of the village council, and city mayor for several towns. He also served as county physician and health officer there for many years. He was married twice and died October 16, 1935.

C. Archibald Leslie or (Archibald C. Leslie) practiced in Fisher from about 1895 through 1900. He was a graduate of McGill University in 1890, and was licensed in Minnesota, October 10, 1890 (License No. 129). In 1903 and 1905, he is listed in Snyder, Texas, and in 1909 in Hannaford, North Dakota. Later he was apparently located at Kathryn, North Dakota. He died about October 23, 1914, at McVile, North Dakota, at the age of fifty-four.

Adolph Oscar Loe practiced in Crookston in 1898, but in 1903 he is listed in Seattle, Washington. He died there suddenly on July 31, 1935, at the age of sixty-three. Dr. Loe was a graduate of the College of Medicine and Surgery of the University of Minnesota in 1897, and was licensed in the same year on June 10 (Certificate No. 817). He was a member of the Pacific Coast Surgical Association, a fellow of the American College of Surgeons, past president of the King County Medical Society, a member of the State Board of Medical Examiners, and was on the staff of the Seattle General Hospital.

Quincy A. Low: (Dr. Low's full name was John Quincy Adams Low).^{*} Dr. Low was born in Vermont in 1848 and came to this part of the country with his parents in 1860, when they settled in Winona County, Minnesota. After having lived on a farm he enlisted at the age of seventeen in the Second Minnesota Regiment of Cavalry in February, 1865, and was discharged in November of the same year. After his return, he entered Hamline College at Red Wing and completed his course in four years. Then he read medicine for three years with Drs. William H. H. Richardson and Franklin Staples of Winona, and during this time he completed two courses of lectures at the University of Michigan Medical Department. He graduated from the Long Island College Hospital, New York, in 1873, where he also took some special training in surgery.

Shortly after graduation, he practiced in Rochester, Olmsted County, in 1873. In January, 1874, he moved to Wabasha where he remained in practice for twenty-five years. He became a member of the Wabasha County Medical Society, and was its secretary for several years. He was elected to membership in the State Medical Association at an early period and also joined the American Medical Association. He received his Minnesota license in 1883 and in the same year became health officer of Wabasha County. In the early Nineties, he was a member of the local United States Board of Pension Examiners. It was not until about 1900 that he moved to a farm near Crookston, where he continued to practice medicine.[†] This he continued until 1907, when he moved to California.

Archibald McEachran practiced in McIntosh about fourteen years. He was

^{*}"History of Medicine in Wabasha County," MINNESOTA MEDICINE, p. 925 (Nov.) 1944. "Medicine and Its Practitioners in Olmsted County Prior to 1900," MINNESOTA MEDICINE, pp. 65-66 (Jan.) 1951.

[†]*The Northwestern Lancet*, (Nov. 15) 1907.

born in Crinan, Ontario, on May 26, 1866, and attended high school in the same town. He received his medical education at the University of Michigan at Ann Arbor, Department of Medicine and Surgery, graduating in 1889. He came to McIntosh in the same year and remained there until at least 1903. His Minnesota license is dated October 4, 1889 (License No. 84). From 1905 on, he is listed in Minneapolis. His death notice in the *Journal-Lancet* of May 14, 1935, states that he died in Minneapolis on April 11 of that year, having practiced there for more than thirty years. At the time of his death he was sixty-nine years old. He had taken postgraduate courses in Chicago in 1896 and 1903 and in Christiana, Norway, in 1904. During the first world war, he was acting captain in the British Canadian recruiting commission at Minneapolis, July, 1917, to October, 1918. He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was in general practice a total of forty-six years, continuing until about a month before his death. Dr. McEachran was survived by his wife, Amy B. McEachran, two sons, Stewart and Beresford, and several brothers and sisters. He was a member of the Masonic Lodge, the Odd Fellows, MWA, and KOTM.

Daniel McEachran was in Fosston around 1896. He graduated from the University of Michigan in 1886 and was licensed in North Dakota in the same year. He received his Minnesota license on January 7, 1889 (Certificate No. 45) and was licensed in Washington in the same year. He apparently was in St. Paul in 1890, and a Minnesota Directory lists him in Fosston in 1895. In 1896, he and Dr. Umland were the only legally licensed physicians in Fosston. It is not known how long he stayed there, but in 1909 he is listed in Stanwood, Washington. He died on February 25, 1925 in Seattle.

Malcolm McKinnon was practicing in Erskine in 1896, but apparently remained there only a short while. He had graduated from Trinity Medical College, Toronto, Ontario, Canada, in 1895 and was licensed in Minnesota in the same year on June 11 (Certificate No. 550). In 1898, a Minnesota Directory lists him in Roseau, while in 1903 and 1905 he is listed in Fosston, and in 1909 in Sand Point, Idaho. Dr. McKinnon was killed in an automobile accident near Baker City, Oregon, in July 1919.

Thor O. E. Moeller was in Fertile in the 1890's. He was born about 1863 and studied medicine at Rush Medical College, Chicago, graduating from that school in 1892. He was licensed on June 14, 1896 (Certificate No. 613) and is listed in Fertile in that year and in 1898. Then he moved to North Dakota; he was in Hillsboro around 1903 and 1905, later in Devils Lake and Lisbon. He served in the first World War. In 1927 he was listed in Chicago. Dr. Moeller died in Fargo in the Veterans Administration Hospital on September 3, 1950 at the age of eighty-seven.

George Alfred Morley was born in Necedah, Juneau County, Wisconsin, March 15, 1868. His father, Alfred Morley, was born in the state of New York; his mother, Jane Stinson, in Ireland. He graduated from Rush Medical College, Chicago, in 1897 and was licensed in Minnesota in the same year specializing in diseases of the eye, ear, nose and throat. At one time he was pension examiner. He was on the staff of St. Vincent and Bethesda Hospitals. He was a member of the Red River Valley Medical Society, serving in several of the offices of the Society, Minnesota State Medical Association, American Medical Association and Academy of Ophthalmology and Otolaryngology. Dr. Morley was an outdoor man, and had one of the first cars in Crookston. He later owned a White Steamer. He died November 18,

1947 at the age of seventy-nine, when he was the oldest practitioner of Crookston. He had been president of the Crookston School system. His wife, Stella McIntyre Morley, took an active part in club work and the Medical Auxiliary. She preceded him in death. He left two children, Donna and Robert Morley.

Andrew Nelson practiced in Maplebay in 1896. Nothing is known about him. However, a Dr. Anders Nilsen, whose name is occasionally given as Andrew Nelson and Anders Nielson, was at Lillian Lake, Kandiyohi County, between 1894 and 1909. There is a possibility that these two are identical.

Arne Nelson came early to Polk County, locating in Aldal in 1880 or 1881. Before that he had practiced in Hartland, Freeborn County, from 1878 and 1880.** From 1890, he is listed in Fertile until his death on May 2, 1908. He was born March 9, 1851 in Norway and was a physician as well as a druggist. He died at the age of fifty-seven from the after effects of injuries sustained in a fall.

Paul O. Neraal (P. O. Nerall) graduated from the University of Iowa, Iowa City, in 1897 and was licensed in the same year on June 10 (Certificate No. 825). He practiced in Independence, Iowa, for a while in 1897 and 1898, but it seems he soon moved to McIntosh where he practiced until at least 1909. He was considered a capable physician. Later he went into a large practice in the West. In 1927, he was listed in Cut Bank, Montana, where he is still located (1956).

Ole Hansteen Olson is listed in the medical directory of 1900, in Erskine. He did much country work there. During his later years, he was not well, finally retiring about 1930. He was born in Norway, October 23, 1862. He was married and had four children. Dr. Olson, who was licensed in 1887, was a member of the Red River Medical Society and the Minnesota Medical Association.

John Nelson Risjord (Richard) was born in Telemarken, Norway, on December 22, 1863 and came to the United States in 1882, locating at Mt. Horeb, Wisconsin. The following year, he came to Fertile, where he stayed four years. He returned to Norway, attended a seminary for one year; then came back to Wisconsin and studied at a business college at Madison for two years. Following this, he edited a newspaper at Mt. Horeb for three years. He sold his interest in the newspaper and began the study of medicine at the Keokuk Medical College, Keokuk, Iowa, graduating in 1898 at the age of thirty-five.

For one year, he practiced in Kenseth, Iowa, and then moved to Fertile where he continued to practice for twenty-seven years until his death. Dr. Risjord was one of the pioneer settlers of Fertile, serving the community well as a physician. He also held the posts of mayor, council member and member of the Board of Health. He was interested in the agricultural development of that area and owned a considerable amount of farmland. Dr. Risjord became one of the outstanding citizens of his community. He was married and had four children who survived him. One son practiced in Chicago (1926) and a daughter taught school in Hibbing (1926).

John C. Rosser practiced in Fosston in 1899 and in Crookston in 1900. He was born in Lynchburg, Virginia, December 2, 1840 and was graduated from Jefferson Medical College, Philadelphia, in 1867. He served in the Civil War as surgeon and hospital steward in the 28th Texas regiment. In 1871, he settled in Brainerd and continued to practice there into the early 1880's. During the 1883 smallpox epidemic in the lumber camps of northern Minnesota, Dr. Charles N. Harth, execu-

**"Notes on Medicine in Freeborn County, 1857-1900," MINNESOTA MEDICINE, p. 76 (Jan.) 1949.

tive secretary of the State Board of Health, appointed him health officer in charge of the infected district; Dr. C. Scoboria, of Elk River, was named his assistant.** He was in Polk County around the turn of the century. In 1902 and 1904, he was listed in West Superior, Wisconsin. According to other information, he practiced in Grand Rapids from about 1895 through 1905. In 1909, he was listed without address. He was licensed in Minnesota, November 24, 1883 (Certificate No. 400). Dr. Rosser died April 25, 1914.

H. William Smith was graduated from the College of Medicine and Surgery, University of Minnesota, in 1897. Coming to Crookston soon afterward, he engaged in the practice of medicine and surgery. He did a relatively large amount of surgery, and was considered to have a high degree of skill and good judgment. He was on the staffs of both Bethesda and St. Vincent's Hospitals. He was called often by other physicians as a consultant, especially in surgical cases, where the patient might be brought later by wagon to the hospital. He employed Dr. Just as an anesthetist. Dr. Smith spent some time in hunting and fishing and was the early owner of an automobile. One such car was a high-wheeled machine supposedly able to run along in the ruts made by wagon in the mud in the Spring. Dr. Smith married Stella Monroe. When he retired from practice, he went West where he resided a few years. He died March 18, 1918. Dr. Smith was a member of the Red River Valley Medical Society, the State Medical Association and the American Medical Association.

Paul Sorkness* was listed in Fisher in 1896. He was a graduate of the College of Medicine and Surgery of the University of Minnesota, class of 1895 and he was licensed on June 11 (No. 526). In 1898, he was listed in Lake Park (Becker County). From 1903 on, he was listed in Fargo, North Dakota, but he probably came there a couple of years before, because when he died, September 23, 1920, he supposedly had practiced about twenty years in Fargo.

Dr. Sorkness was a highly respected physician and was very active in local and state medical affairs. He was at one time president of the North Dakota State Medical Association and the State Board of Medical Examiners. He was a member of the Western Surgical Association and served as local surgeon of the Northern Pacific and the Chicago, Milwaukee and St. Paul railroads. At one time, he was health officer of Fargo and Cass counties.

Albert Madison Stebbins was in Fertile in 1895, but in 1896 he was listed at both Fertile and Maplebay. He graduated from the College of Medicine and Surgery, University of Minnesota, in 1896 and was licensed October 5 of the same year (No. 478). His death occurred on July 21, 1897 while practicing in Fertile.†

Lemuel S. Stowe was listed in Crookston and Carman in 1890, but no doubt settled earlier, perhaps even in the early 80's in Crookston. He graduated from the University of Nashville, Tennessee, in 1865 and from the Vanderbilt University Medical Department, Nashville, Tennessee. In 1895 and 1898, directories listed him in Hartley (Clay County) and between 1903 and 1909, without an address.

Daniel Tufte supposedly practiced in Crookston in the early 1900's, however, very little is known about him. He graduated from the University of Christiania,

**Philip D. Jordan: *The People's Health*, pp. 200-201. Minnesota Historical Society, 1953.

**J.A.M.A.*, 75: (Oct. 30) 1920, and *Journal-Lancet* 40: (Oct. 15) 1920.

†*University of Minnesota Alumni Directory* of 1940 and *The Journal AMA*, 1897. No official record of his death could be found in Polk County or the State Department of Health.

Norway, in 1893 and was licensed in Minnesota, October 12, 1897. In 1898, he was in Nelsonville, Wisconsin, and between 1903 and 1909 he is listed in Pelican Rapids (Otter Tail County). He may have been in Fargo, North Dakota, for a while around 1905. He died in Germany, November 10, 1915.

Ernest A. Umland was listed in Fosston in 1893 and 1896. In the latter year, he and Dr. Daniel McEachran were the only legally-licensed physicians in Fosston. It seems he was in Polk County as late as 1900. Dr. Umland was licensed in Minnesota, October 12, 1883 (No. 135) but his location prior to 1893 is not known. He died in December, 1900.

Milton VanDyke graduated from Rush Medical College, Chicago, in 1880, and was licensed in Minnesota, December 31, 1883 (Certificate No. 586). He was in Crookston in 1886 or before. He was also a graduate of a pharmaceutical school and owned a drugstore in Crookston, a building which is still standing (1954). He sold his personal holdings in Crookston, including the drugstore, in 1893 and moved to Seattle, Washington, where he developed a successful practice. He continued in his profession until he died in December, 1923.

There were other medical men in Dr. VanDyke's family: Dr. Frank VanDyke, a cousin, who became chief surgeon for the Great Northern Railroad, practicing in Williston, North Dakota; Dr. John Henry VanDyke, a nephew, who practiced a short time in the hospital at Starbuck as locum tenens physician, and for a short while in the same capacity in a northern Minnesota town before moving to Long Beach, California, where he still practices (1954). Another nephew, Dr. Arthur VanDyke, practiced as dentist in St. Paul and has been St. Paul's postmaster for many years.†

James F. Warren practiced in Fisher about 1900. He had been in Sprague, Missouri, in 1896 (according to Polk's Medical Directory). Dr. Warren was not licensed in Minnesota and nothing more is known about him.

Mathew Watts practiced in Crookston from 1886 into the 1890's. He had graduated in medicine in 1878, and was mentioned in connection with the County Hospital in Crookston. He was a brother of Judge William Watts, District Judge, who also lived in Crookston. From some of the older men who remember him, the report is that he was a very conscientious, hard-working general practitioner. In 1895, he was taken ill with typhoid and died in the local hospital. However, Polk's Medical Directory listed him in Crookston as late as 1898, then without address until 1909.

William H. Welch probably was the first physician in Crookston. He is mentioned there as having reported a case of smallpox. The patient was quarantined in a newly-built pesthouse, where he apparently was well taken care of and recovered in due time. Dr. Welch graduated from the University of Vermont Medical Department, Burlington, Vermont, in 1880. He is listed in St. Hilare in 1886 and 1890; it is assumed that he moved there from Crookston. In 1927, he was listed in Larimore, North Dakota, and as late as 1934 when he was seventy-nine years old. He died May 11, 1948, at the age of eighty-nine.

†Communication from Dr. Arthur A. VanDyke, St. Paul, 1954.

Meetings and Announcements

STATE

Northern Minnesota Medical Association, annual meeting, Hibbing, Minnesota, September 6 and 7, 1957.

Southern Minnesota Medical Association, annual meeting, Lake City, Minnesota, September 9, 1957.

NATIONAL

American College of Physicians, Midwest regional meeting, Urbana, Illinois, October 12, 1957.

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

American Gastroenterological Association, 59th annual meeting, Washington, D. C., May 30-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

Midwest Cardiac Conference, Iowa State University Hospitals, Iowa City, Iowa, October 3-5, 1957.

Ninth Postgraduate Assembly in Endocrinology and Metabolism, Medical College of Georgia, October 21-25, 1957.

INTERNATIONAL

Congress of International Society for Cell Biology, St. Andrews, Fife, Scotland, August 28-September 3. Prof. H. G. Callan, Bell Pettigrew Museum, The University, St. Andrews, Fife, Scotland.

Congress of International Society of Orthopedic Surgery and Traumatology, Barcelona, Spain, September 16-21. International Society of Orthopedic Surgery and Traumatology, 34 rue Montoyer, Brussels, Belgium.

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. Dejardin, 141 rue Belliard, Brussels, Belgium.

Fifth International Congress of Internal Medicine, Philadelphia, Pennsylvania, April 24-26, 1958. Edward R. Loveland, Secretary-General, 4200 Pine Street, Philadelphia 4, Pennsylvania.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

International Conference of Ultrasonics in Medicine, Statler Hotel, Los Angeles, California, September 6-7, 1957. John H. Aldes, M.D., Secretary, 4833 Fountain Avenue, Los Angeles 20, California.

Pan-Pacific Surgical Association, Seventh Congress, Honolulu, Hawaii, November 14-22, 1957. Dr. F. J.

Pinkerton, Director General, Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, Hawaii.

World Congress of Gastroenterology, Washington, D. C., May 25-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

UROLOGY AWARD

The American Urological Association is offering an annual award of \$1,000 for essays on the result of some clinical or laboratory research in urology. First prize is \$500, second prize \$300, and third prize \$200. Competition is limited to urologists who have been graduated not more than ten years, and to hospital interns and residents doing research in urology. The first prize essay will appear on the program of the meeting of the American Urological Association to be held at the Roosevelt Hotel, New Orleans, Louisiana, April 28-May 1, 1958.

Full information may be obtained from William P. Didusch, Executive Secretary, American Urological Association, 1120 North Charles Street, Baltimore, Maryland. The deadline for essays is December 1, 1957.

OLIVIA GIRL WINS 1956 AAPS ESSAY CONTEST

Miss Sonia Gustavson, eighteen-year-old Olivia, Minnesota, girl, received a first prize award of \$1,000 in the 1957 national essay contest sponsored by the Association of American Physicians and Surgeons Freedom Programs, Inc. This was the eleventh annual national contest and Miss Gustavson's topic was "The Advantages of Private Medical Care." She was presented with her award at the commencement exercises of the Olivian High School on May 29. The day also happened to be her birthday. Miss Gustavson plans to begin her course in pre-medicine at the University of Minnesota this fall.

The national essay winner was sponsored by the Renville-Redwood County Medical Society, with Dr. J. A. Cosgriff, Olivia, in charge. An interesting sidelight is the fact that Dr. Cosgriff delivered Sonia eighteen years ago.

The Renville-Redwood Society presented Miss Gustavson with \$15.00 for first prize within the society and gave a \$10.00 second prize and a \$5.00 third prize.

Miss Gustavson was present at the annual banquet of the Minnesota Academy of General Practice, Monday, May 13, and was introduced to the group by Dr. Cosgriff.

The 1958 essay contest will be sponsored by the Minnesota State Medical Association as a result of action of the House of Delegates at the 104th annual meeting.

Woman's Auxiliary

NEW OFFICERS ELECTED

Mrs. C. L. Oppegaard, Crookston, was installed as president of the Woman's Auxiliary to the Minnesota State Medical Association for the year 1956-57 at the thirty-fifth annual meeting held May 13-15 in St. Paul. Mrs. Reuben Erickson, Minneapolis, was elected president-elect. Other new officers include Mrs. M. F. Fellows, Duluth, first vice president; Mrs. Harold Peterson, St. Paul, second vice president; Mrs. J. A. Cosgriff, Olivia, third vice president; Mrs. J. A. Bargen, Rochester, fourth vice president; Mrs. Stanley Peterson, Austin, recording secretary; Mrs. John Cameron, Crookston, corresponding secretary; Mrs. Gilman Goehrs, St. Cloud, treasurer; Mrs. G. E. Penn, Mankato, auditor; Mrs. Philip Arzt, St. Paul, historian, and Mrs. Leo W. Fink, Minneapolis, parliamentarian.

Dr. Wallace E. Anderson, Clearbrook, Dr. J. A. Bargen, Rochester, Dr. O. J. Campbell, Minneapolis, Dr. A. O. Swenson, Duluth and Mr. R. R. Rosell, St. Paul, make up the medical advisory council.

Regional advisers include: Mrs. Howard F. Polley, Rochester, first district; Mrs. David Halpern, Brewster, second district; Mrs. M. I. Hauge, Clarkfield, third district; Mrs. Alton E. Lindblom, North Mankato, fourth district; Mrs. W. P. Gardner, St. Paul, fifth district; Mrs. Arthur N. Russeth, Minneapolis, sixth district; Mrs. Leslie Evans, Sauk Rapids, seventh district; Mrs. Robert Estrem, Fergus Falls, eighth district and Mrs. Andrew Sinamark, Hibbing, ninth district.

The advisory committee includes Mrs. H. H. Fesler, St. Paul; Mrs. Peter Rudie, Duluth; Mrs. L. P. Howell, Rochester; Mrs. C. L. Sheedy, Austin, and Mrs. H. F. Wahlquist, Minneapolis.

Committee chairmen and national officers will be announced in next month's issue.

Nearly 300 women attended the 1957 meeting sessions which were held at the Hotel Lowry. A vote of thanks is extended to the Ramsey County Medical Auxiliary, the hostess group, for an outstanding meeting. Mrs. W. P. Gardner and Mrs. W. P. Ritchie were in charge of general arrangements.

On Monday morning the group toured the Minnesota Mining research center. The executive board meeting and luncheon were also held on Monday and highlighting the day's activities was a lovely tea at the home of Dr. and Mrs. Philemon Roy, North Oaks.

The annual meeting and annual luncheon were held on Tuesday. Schuneman's presented a style show at the luncheon.

On Wednesday morning, the Ramsey County Auxiliary entertained all visiting women at a breakfast in the Hotel Lowry Ramsey Room.

Contributions for this column, including news and activities of State Auxiliary societies and items of interest about members, may be sent to Mrs. A. B. Rosenfield, Woman's Auxiliary Editor, MINNESOTA MEDICINE, 2920 Dean Boulevard, Minneapolis, Minnesota.

NEWS FROM THE COUNTY AUXILIARIES

Hennepin

Mrs. Karl Anderson, Linwood, Lake Minnetonka, is the newly elected president of the Hennepin County Auxiliary. Other new officers are Mrs. Hamlin Mattson, Mrs. Karl Sandt, Mrs. O. L. N. Nelson, Mrs. Elmer Hill, Mrs. Harold Noran, Mrs. Robert Quello, Mrs. Conrad Holmberg, Mrs. Edward T. Evans and Mrs. Sumner Cohen.

Lyon-Lincoln

Members of the Lyon-Lincoln County Medical Society entertained their wives at a clinical meeting and banquet held at the Atlantic Hotel in Marshall in May. Dr. Dorothy Sunberg, of the University of Minnesota, spoke on "Blood."

Wabasha

Dr. and Mrs. William Gjerde, Lake City, opened their home to wives of doctors attending the South-eastern Minnesota General Practitioners course held in Lake City recently. An evening banquet was given for the doctors and their wives after which the wives adjourned to the Gjerde home.

Zumbro Valley

The Zumbro Valley Auxiliary held its annual Health Day program in May at the Mayo Foundation House in Rochester. Tea was served, followed by the program which included the film "Three to Make Ready" and a report on the Southern Minnesota Ability Building Center by Dr. Frank H. Krusen and David Griggs, managing director of the center.

All Rochester club women were invited to attend this meeting.

PHARMACOLOGY FOR THE FAMILY PHYSICIAN

(Continued from Page 490)

meprobamate or Miltown is characteristic of addiction. From that standpoint we have to watch patients taking these drugs most carefully.

These drugs produce some tendency to sleep, which isn't always desirable. What can one do about it? It is possible to add a central nervous system stimulant and keep the individual a bit more awake during the daytime. Amphetamine or Benzedrine in doses of one or two milligrams may be used. A similarly acting drug is Ritalin,[®] the beginning dose being five to ten milligrams. The third drug is Maratran in one to two milligram doses. These, if used, should be used in the morning or early afternoon, never in the evening, because they might prevent sleep. These seem to be of benefit. Whether this will tend to cancel out the action of the ataractic drugs, only the future can tell.

In Memoriam

HENRY M. LEE

Word has just been received of the death of Dr. Henry M. Lee, Cambridge, Minnesota, in 1956. He was sixty-six years old.

A former Minneapolis surgeon, Dr. Lee left the city in 1950. He received his education at Rush Medical College and had his offices in Minneapolis in the Medical Arts Building for many years.

A former member of the Hennepin County Medical Society, he also belonged to the East Central Minnesota Medical Society, the Minnesota State Medical Association and the American Medical Association.

WILLIAM PAUL OLSON

Dr. William P. Olson, retired Gaylord, Minnesota, physician, died at his home in Los Angeles, California, April 16, 1957. He was seventy years old.

Born in Iowa, Dr. Olson graduated from the University of Minnesota Medical School in 1909 and interned at Ancker Hospital, St. Paul. After practicing in Lafayette, Minnesota, for three years, he moved to Gaylord. He owned and operated the Gaylord Hospital from 1920 to 1938, when he retired and moved to Westwood Village in Los Angeles.

Dr. Olson had been a member of the Camp Release Medical Society, the Minnesota State Medical Association and the American Medical Association. He served as health officer for Gaylord, as Sibley County health officer and county coroner for many years. He was a member of the I.O.O.F. lodge, the Masonic lodge, local fire department and many other local civic organizations.

He is survived by his widow, Grace; one daughter, Mrs. William Paulson, Santa Monica, California; one son, Dr. Duane Olson, Gaylord, and three grandsons.

WILLIAM B. ROBERTS

Dr. William B. Roberts, Minneapolis physician since 1902 and head of Scottish Rite Masons in Minnesota for the past twelve years, died May 8, 1957, at his home. He was eighty-one years old.

Since 1925, Dr. Roberts had been sovereign grand inspector general of Minnesota Masons. He also was a life member of Zuhrah Temple of the Shrine, a member of Joppa Blue Lodge and first chairman of the group which organized the Minneapolis DeMolay chapter in 1915. He was the ranking 33rd degree Mason in the state. The degree was conferred in 1925 in Washington.

Born at Lacon, Illinois, he was the son of the late Dr. George F. Roberts who practiced medicine in Minneapolis from 1882 to 1914.

Dr. William Roberts received his education at the University of Minnesota and Hahnemann Medical School in Philadelphia, Pennsylvania. At the age of fifty-two, he took postgraduate work in Europe. During World War I he served in the medical department of the U. S. Navy. He closed his medical office in Minneapolis in March, 1956, but continued to practice on a limited

basis. He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He became a member of the "Fifty Club" group of the State Medical Association in 1952.

Surviving are his wife, Elizabeth; a son, George F., Roswell, New Mexico; a daughter, Mrs. Francis P. Whiting, Minneapolis; seven grandchildren and one great-grandson.

ALCOHOLISM IN INDUSTRY

(Continued from Page 511)

be capable of benefiting from the AA program. For those patients requiring a longer period of treatment, including hospitalization, the physician would do well to be familiar with the excellent resources available for this purpose in Minnesota. The Willmar and Sandstone state hospitals provide long-term care for alcoholics who are received on a voluntary basis or through court commitment. Pioneer House, a treatment center located at Medicine Lake, is operated by the City of Minneapolis. The Hazelden Foundation operates a private, non-profit, treatment center at Center City for men alcoholics and a similar center at White Bear Lake for women alcoholics.

The alcoholic is often unco-operative, and treatment may be difficult. If an alcoholic gets drunk after much time and effort has been spent with him, the situation can be discouraging. For the physician who intends to work with alcoholics, it is important to remember that the alcoholic is as sick as other patients and requires understanding care.

PATRICK BUTLER, *Chairman
Minnesota Advisory Board
on Problems of Alcoholism*

HEALTH PROBLEMS OF AMERICAN INDIANS

Health problems of the American Indians are discussed in an article published in the July issue of *Public Health Reports*. Based on a survey of health needs of the Indians recently completed by the Public Health Service for Congress, the article defines obstacles to improvement of Indian health and identifies measures which offer promise of more rapid progress.

The article, entitled "Health Services for American Indians," is by George St. J. Perrott and Margaret D. West, survey director and associate director, respectively. Mr. Perrott is chief of the Service's Division of Public Health Methods, and Mrs. West is head of the Health Services Requirements Branch of that division.

General Interest

Dr. M. W. Comfort, member of the staff of the Mayo Clinic, was installed as president of the American Gastroenterological Association on May 19 at Colorado Springs, Colorado. The president-elect of the Association is a former Mayo Clinic staff member, Dr. Clifford J. Barborka, Chicago.

* * *

A lectureship in chest disease, sponsored by the St. Louis County Christmas Seal organization for the St. Louis County Medical Society, has been established in honor of Dr. Arthur T. Laird, Duluth, retired superintendent and medical director of Nopeming Sanatorium, who has been associated with tuberculosis control work in the United States for half a century.

* * *

The Minnesota Academy of General Practice presented its award of merit in May to Dr. Aaron Friedell, Minneapolis.

* * *

On May 10 the National Tuberculosis Association, at its annual meeting in Kansas City, Missouri, named Dr. Mario Fischer, Duluth and St. Louis County director of public health, as its president-elect. Dr. Fischer has previously served as vice president and director of NTA.

* * *

Dr. Ray R. Knight, Minneapolis, was one of two "Town Toppers" sketched in the *Minneapolis Star*, May 15.

* * *

Dr. Edgar V. Allen, senior consultant in medicine at the Mayo Clinic and president of the American Heart Association, addressed the annual meeting of the South Dakota Heart Association at Rapid City, June 1.

* * *

Dr. William C. Bernstein, St. Paul, recently delivered the annual Levin Memorial Lecture at Louisiana State Medical School in New Orleans, sponsored by the American College of Gastroenterology. Dr. Bernstein's subject was "The Detection of Early Lesions of the Large Intestine."

* * *

The only complete museum honoring the late Dr. Walter Reed, conqueror of yellow fever, will be set up at the Mayo Clinic, Rochester. Dr. Philip Hench, staff member of the Clinic, has devoted seventeen years to research into the work done by Reed in Cuba and is the sole source of authentic records on Dr. Reed's activities. The museum will be set up in a room at the New Clinic library.

* * *

The American Board of Plastic Surgery elected Dr. Frederick A. Figi, senior consultant in plastic surgery at the Mayo Clinic, to a one-year term as chairman on May 8.

The Minnesota Society of Internal Medicine held its annual spring meeting at Red Wing, Saturday, May 25. The speaker at the evening dinner was Mrs. Eugenie Anderson, Red Wing, former ambassador to Denmark, whose subject was "From the Front Lines of Freedom." Dr. Walter Neff, Virginia, is president of the group.

* * *

Dr. Fred W. Wittich, Minneapolis, president emeritus of The American College of Allergists, and editor, *Review of Allergy and Applied Immunology*, conducted a scientific exhibit on "Vascular Headaches" at the Section on Internal Medicine of the American Medical Association, held at the Coliseum, New York, June 3-7.

* * *

On June 3, 1957, Dr. C. W. Mayo, head of a section of surgery in the Mayo Clinic and professor of surgery, Mayo Foundation, Graduate School, University of Minnesota, was awarded the honorary degree of doctor of laws by Drake University, Des Moines, Iowa. Dr. Mayo delivered the commencement address at Drake, speaking on "Educational Responsibilities."

* * *

The Minnesota Chapter of Alpha Omega Alpha, honorary medical society, at its annual meeting in May elected Dr. J. S. Blumenthal faculty president. Dr. Blumenthal is clinical associate professor of medicine and director of the Allergy Clinic, Department of Internal Medicine, University of Minnesota Hospitals.

* * *

Dr. Edward M. LaFond, St. Cloud, has been appointed recently as city physician and health officer, succeeding Dr. William Autrey. Dr. LaFond, who is a specialist in orthopedics, has been practicing medicine in St. Cloud for a year and a half.

* * *

Dr. Robert F. Schnabel, Omaha, Nebraska, has recently joined the staff of Northwestern Clinic, Crookston, as pediatrician. Dr. Schnabel received his medical degree from the Medical College of Virginia, at Richmond, Virginia, and received special training in pediatrics at the Raymond Blank Memorial Hospital for Children in Des Moines, Iowa.

* * *

Dr. Ralph Nyhus joined the staff of the Mesaba Clinic, Hibbing, on June 1. Dr. Nyhus, a pediatrician, took his internship in pediatrics at the University of Minnesota hospitals, and has completed a three-year fellowship in pediatrics at the Mayo Clinic. He is certified by the American Board of Pediatrics.

BROAD ANTICHOLINERGIC BLOCKADE

Pro-Banthine® Relieves Pain, Accelerates Peptic Ulcer Healing

The efficiency of Pro-Banthine (brand of propantheline bromide) in inhibiting the chemical substance which mediates parasympathetic gastric activity explains the success of the drug in ulcer therapy. Pro-Banthine blocks acetylcholine at both the ganglia and parasympathetic effector sites. This dual action controls excess neural stimulation of both gastric secretion and motility.

The therapeutic benefits of this anti-

cholinergic blockade consist, as many clinical investigators have noted, in prompt relief of ulcer pain and pronounced acceleration of ulcer healing.

The suggested initial dosage is one 15-mg. tablet with meals and two tablets at bedtime. Two or more tablets four times a day may be indicated in severe manifestations. G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

A New Quick-Reference Text

GIUS'

Fundamentals of General Surgery

Ideal for all doctors of medicine who feel the need for re-establishment of background in surgical fundamentals

Stressing the pathophysiologic mechanisms of surgical diseases, Dr. Gius describes in brief, easy-reading style the essential facts and factors—short of actual operative technic—surrounding the management (both diagnostic and therapeutic) of the surgical patient.

Nor is this book confined only to the problems of major surgery. Specific and useful guidance is also included for application to conditions which frequently are treated in the office of both the general practitioner and the surgeon.

More than 20 years of surgical experience have gone into the writing of this book...private and university hospital practice, extensive teaching at both undergraduate and postgraduate levels, military practice, and clinical research. Every one of the 31 chapters reflects this broad background and the resulting capacity to separate the wheat from the chaff.

Well illustrated, expertly written, thoroughly up-to-date, this new book will indeed prove a boon to physicians seeking refresher material. Professors of surgery will quickly discover it to be the ideal text for instructing students in the basic elements of general surgery.

By JOHN ARMES GIUS, M.D., *Professor of Surgery, College of Medicine, State University of Iowa*. 720 pages; 275 illustrations on 151 figures. \$12.50.

MINNESOTA BLUE SHIELD-BLUE CROSS

Minnesota Blue Shield paid physicians \$2,837,171 during the first four months of 1957 for 99,509 services to participant subscribers. These figures represent increases of approximately 28 per cent and 30 per cent, respectively, over the amount, \$2,215,225, and the number of services 76,204, paid by Blue Shield the first four months of 1956.

Blue Shield payments to physicians for subscribers' benefits during the first four months of 1957 are equal to average monthly payments of \$709,293 and exceed by \$621,946 the total amount of claims paid by Blue Shield for the same four months in 1956.

Participant subscribers with Minnesota Blue Shield numbered 837,565 as of April 30, 1957 compared with 753,910 participant subscribers enrolled as of the same date in 1956. During the twelve months prior to April 30, 1957, the number of participant subscribers increased 83,655 or approximately 11 per cent.

While it is apparent that the number of Blue Shield subscribers increased substantially from April 30, 1956, to April 30, 1957, it is equally apparent that the enrollment increase alone does not account for the great increases in the number of services paid by Blue Shield or the total amount paid during the first four months of 1957 as compared with the same four months of 1956.

During the first four months of 1957, Minnesota Blue Cross payments to hospitals amounted to \$9,367,111.89, an increase of \$1,700,589.58 compared to the \$7,666,522.31 paid to hospitals during the same period of the preceding year.

This increase in hospital payments is attributable not only to increased enrollment, but also to the continuing trend of higher level of Blue Cross contractual benefits which have been adopted by Blue Cross members.

Blue Cross participant subscribers totaled 1,111,141 as of April 30, 1957, an increase of 67,503, as compared to 1,043,637, Minnesotans enrolled in Blue Cross as of April 30, 1956.

During the first four months of 1957, 417,797.6 days of hospital care were provided for 67,239 participant subscribers compared to 374,167.2 days provided for 60,421 participant subscribers during the comparable period of 1956. Although the average length of hospital stay remained at 6.2 days per case, usage increased 3.6 per cent from 468 to 485 cases paid per year per 1,000 contracts protected.

This increase was divided fairly evenly between surgical and medical care with obstetrical cases showing no increase in incidence rate.

Accident cases showed the greatest single increase in incidence: 1,500 more cases paid representing six more cases paid per year per 1,000 contracts.

THE THYROID

One of the most important and neglected diagnostic features of the thyroid is the age of the patient. In patients under forty, any history of sudden increase in size or pressure, change or loss of voice, firmness or consistency, or fixation to surrounding tissue should be regarded as an indication for immediate surgery.

Out of 5,000 thyroidectomies for nodular goiter at the University of California Hospital, 300 carcinomas were found.

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. A TEXT BOOK OF PATHOLOGY. By E. T. Be
 M.D., Emeritus Professor of Pathology in the Unive
 sity of Minnesota. Contributors: B. J. Clawse
 Emeritus Professor of Pathology in the University
 Minnesota and J. S. McCartney, Professor of Patholo
 in the University of Minnesota. 8th ed. 1028 pag
 Illus. Price \$14.50. Philadelphia: Lea & Febig
 1956.

The eighth edition of "Text Book of Pathology"
 E. T. Bell, M.D., continues to be one of the best te
 books of pathology published. New material has be
 added since the seventh edition, keeping the book abre
 of present-day opinions about various diseases.

No other text book can bring a topic into such sha
 focus with so few words as does this text book. O
 can find the most complicated pathological proble
 reduced to a few sentences, which still give the read
 working knowledge of his subject.

The author is to be particularly commended for addi
 clinical information to the discussion of pathological co
 ditions. The book thus becomes of use to the clinici
 as well as the pathologist and student.

This text book is highly recommended for anyone
 any phase of medical work. To those in research wor
 it should be of great value because of its excelle
 references on almost all topics.

Clinical Variations in Cystic Fibrosis of the Pancreas

BURTON FEINERMAN, M.D.
EDMUND C. BURKE, M.D.
Rochester, Minnesota

GR^EAT variation occurs in the clinical manifestations of cystic fibrosis of the pancreas. Recent studies of patients with this disease suggest that it is a generalized condition in which all exocrine glands are affected.¹⁻³ The purpose of this paper is to discuss the unusual clinical picture seen in some of these patients.

Table I lists the significant clinical and laboratory findings in the forty-four patients, whose ages ranged from three months to fourteen years when first seen at the clinic. Table II illustrates the variations in signs, symptoms and results of laboratory studies in six of these patients.

The following four cases are reported in detail because of their unusual clinical manifestations.

Report of Cases

Case 1.—A four-year-old girl was brought to the clinic because of respiratory distress and generalized anasarca. The child had been premature at birth, weighing 4 pounds, 10 ounces. She was dismissed from the hospital at one month of age, with a weight of 5 pounds. Cough and difficulty in breathing appeared when she was seven weeks of age. A diagnosis of pneumonia was made, and she was hospitalized for three weeks. Her gain in weight was poor. Pneumonia developed again at the age of six months; she was treated for several weeks at another hospital, where a diagnosis of cystic fibrosis of the pancreas was made. She was dismissed, with the advice to continue maintenance doses of antibiotics and pancreatic granules. When she was one year of age, it was first noted that her stools were large and foul-smelling. At two years, she became weak, listless and dehydrated during a heat wave and required administration of fluids and electrolytes. She continued to have frequent upper respiratory infections.

Seven months prior to admission, generalized edema developed and then disappeared within three days after treatment by the family physician. She had three similar

Dr. Feinerman is a Fellow in Pediatrics, Mayo Foundation. Dr. Burke is in the Section of Pediatrics, Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

attacks after this, which responded to medical management. One week prior to admission, anasarca again developed and did not respond to therapy. She became dyspneic, orthopneic and oliguric. The family history revealed that a male sibling had died at eight months of age from cystic fibrosis of the pancreas.

On admission to the clinic, the child was in acute respiratory distress. The temperature was 99° F., the pulse rate was 120 beats per minute and the respiratory rate was 70. Pitting edema of the legs and arms and the abdominal and thoracic walls was present, with considerable ascites. Moist rales were audible at the bases of both lungs. The second pulmonic heart sound was accentuated, and a friction rub was heard over the left parasternal border in the fourth intercostal space. Clubbing of the fingers and toes was present.

A thoracic roentgenogram revealed diffuse congestion in both lungs and cardiac enlargement. An electrocardiogram disclosed right ventricular hypertrophy (systolic overload type of pattern) and cor pulmonale. Blood studies showed the following values (in milliequivalents per liter): sodium, 138; potassium, 4.2; chlorides, 97; and carbon dioxide, 28. Despite administration of antibiotics, acetazoleamide (Diamox) and a cardiac glycoside (Digoxin), the patient died twelve hours after admission.

Necropsy revealed cystic fibrosis of the pancreas, congestion and fibrosis in both lungs, and cardiac enlargement, particularly of the right ventricle.

Case 2.—A three-year-old boy was admitted because of persistent fever, cough, rash and pains in the joints. At seven months of age, he had been hospitalized elsewhere because of anorexia, poor gain in weight, and large, foul-smelling stools. A diagnosis of cystic fibrosis of the pancreas was made. Pneumonia developed when he was two years old and he received antibiotics. Intermittent bouts of fever, cough, generalized rash and pains in the knees and elbows began seven months prior to admission. These symptoms persisted until his admission.

Examination at the clinic revealed a poorly developed, poorly nourished, twenty-six-pound child with some muscular wasting and a protuberant abdomen. Cervical, axillary and inguinal lymph nodes were palpable; they were discrete, nontender and freely movable. A fine papular rash was present over the trunk, face and legs, and small erythematous lesions were noted over the

knees and elbows. Petechiae were found on the legs. Tenderness was present on palpation and motion of the knees. A barrel-shaped thorax was noted. The liver was palpable 3 cm. below the costal margin, and the spleen was palpable 2 cm. below this margin.

A thoracic roentgenogram showed increased broncho-vascular markings bilaterally. Duodenal drainage revealed an absence of trypsin, lipase and diastase. Culture of the throat showed an abundance of *Micrococcus pyogenes*; results of blood culture were negative. The value for hemoglobin was 12 gm. per 100 ml. of blood. Leukocytes numbered 6,100 per cubic millimeter of blood, with the following distribution: lymphocytes, 5 per cent; monocytes, 8 per cent; segmented neutrophils, 44 per cent; band neutrophils, 23 per cent; basophils, 1 per cent; metamyelocytes, 2 per cent; late myelocytes, 3 per cent; early myelocytes, 2 per cent; progranulocytes, 1 per cent; and blast cells, 11 per cent. Platelets were reduced to 26,000 cells per cubic millimeter of blood. The Quick prothrombin time was 22 seconds (normal, 17 to 19 seconds); the coagulation time was 4 minutes and the bleeding time 6 minutes. The bone marrow contained many stem cells, some with large nucleoli, others with nucleoli of varying size; a large number of cells were differentiating into reticular mononuclear cells. Some plasma cells were seen, but only an occasional immature megakaryocyte was noted. Opinion was divided as to whether the picture was that of a reactive bone marrow secondary to some toxic agent or of leukemia. He was dismissed, with a plan for follow-up studies in the near future. Melena, hematuria and bleeding from the gums appeared one month later, and he was admitted to a hospital near his home. Examination at that time revealed generalized lymphadenopathy, hepatosplenomegaly and ascites. Rales were heard posteriorly at the base of the left lung. Study of the blood revealed significant changes. The hemoglobin now measured 5.5 gm. The leukocyte count was 127,000, with 28 per cent segmented neutrophils, 24 per cent nonsegmented neutrophils, 7 per cent metamyelocytes, 8 per cent myelocytes, 1 per cent promyelocytes, 1 per cent basophils, 8 per cent monocytes, 18 per cent lymphocytes and 5 per cent blast cells. A diagnosis of leukemia was made. Despite treatment with cortisone, blood transfusions and antibiotics, the child died two months later.

Necropsy done elsewhere disclosed leukemic infiltration in the lungs, liver, gallbladder, esophagus, stomach and intestines. Purulent material was noted in the bronchi. The parenchyma of the pancreas was almost completely gone, with only ducts, islets and dense connective tissue remaining, the whole being infiltrated with leukemic cells.

Case 3.—A nine-month-old girl who had been diagnosed previously at the clinic as having cystic fibrosis of the pancreas was admitted because of vomiting and dehydration. The patient had a history of foul-smelling stools since two months of age and recurrent infections of the respiratory tract since the age of three weeks. One sibling had died of cystic fibrosis of the pancreas.

During a heat wave, she became greatly dehydrated

over a period of two days. Her appetite became poor and she vomited most of her feedings. On admission, she appeared poorly nourished (weight, 9 pounds) and dehydrated, with sunken eyes, dry tongue and lips, and poor cutaneous turgor. Sternal retraction was present, and moist rales were heard at the bases of both lungs. The abdomen was protuberant.

A thoracic roentgenogram revealed patchy pneumonitis in both lung fields. *M. pyogenes* and *Pseudomonas* organisms were cultured from the throat. The value for blood urea was 36 mg. per 100 ml. Chlorides measured 86 mEq. per liter, and the carbon dioxide was 38 mEq. The infant died despite intravenous administration of fluids, later feedings through a polyethylene tube and large doses of antibiotics.

Necropsy revealed cystic fibrosis of the pancreas and suppurative pneumonitis.

Case 4.—A seven-year-old boy was admitted because of dyspnea and cough. At the age of three years, he had had pneumonia and since that time had experienced repeated infections of the respiratory tract. A cough developed that became progressively worse and produced thick, sticky, yellowish-green sputum. His stools were normal. He tolerated exercise poorly and was dyspneic at rest.

On admission to the clinic, the boy appeared chronically ill. Clubbing and cyanosis of the fingers and toes were evident. His thorax was barrel-shaped, and rales were heard at the bases of both lungs.

A thoracic roentgenogram disclosed a diffuse inflammatory process in both lung fields, particularly in the lower portions, suggestive of bronchiectasis. The serum proteins were normal. Studies of sputum were negative for fungi but showed an abundance of *M. pyogenes* and *Hemophilus influenzae*. Results of tuberculin tests were negative. Study of material obtained by duodenal drainage revealed the following concentrations: trypsin, 2 ml. of N/10 sodium hydroxide; diastase, 1.4 gm. of maltose; lipase, 80 ml. of N/20 sodium hydroxide. Study of sweat showed that it contained 150 mEq. of chlorides per liter. Electrocardiography disclosed right ventricular hypertrophy. Despite the presence of duodenal enzymes, a diagnosis of cystic fibrosis of the pancreas was made because of the prominent pulmonary findings and the abnormal chemical composition of the sweat.

Comment

Case 1 was unusual because of the extreme generalized edema. The vast majority of patients who have cystic fibrosis of the pancreas have values for serum protein that are within the normal range. It is extremely rare for these patients to have hypoproteinemia severe enough to produce edema. May⁴ stated that a patient who has both cystic fibrosis of the pancreas and edema most likely has cor pulmonale or cirrhosis of liver as a complicating factor. It has been estimated that about a third of patients with cystic fibrosis have

signs of cardiac failure before death.⁵ A direct relationship apparently exists between the degree of right-heart strain and the severity of pulmonary involvement. Children with this disease should be studied electrocardiographically to determine the degree of right ventricular hypertrophy, which is important in evaluating prognosis. Infants who show signs of failure of the right side of the heart may respond to therapeutic measures early in their management. Eventually, however, the cardiac failure becomes irreversible, and the patients become resistant to diuretics and digitalis.

The unusual association of leukemia with cystic fibrosis of the pancreas was present in Case 2. This patient also illustrated the fact that, despite characteristic signs and symptoms of leukemia, blood studies early in the disease may not be diagnostic.

Management of patients with cystic fibrosis during warm weather can offer many problems, as seen in Case 3. This is particularly true when fluid is lost by vomiting or diarrhea, in addition to the electrolytes excreted in abnormal amounts in the sweat. Gochberg and Cooke⁶ recently demonstrated that an abnormally high concentration of sodium chloride occurs in the sweat of patients who have cystic fibrosis. In their study, the concentration of sodium in the sweat of such patients averaged 79 mEq. per liter, while the average concentration in controls was 18 mEq. Obviously, therefore, the patient who has cystic fibrosis is in grave danger of depletion of salt and water during stress from high environmental temperatures. Maintenance of fluid and electrolytic balance by means of parenteral therapy is necessary. Even with the most vigorous type of treatment, these patients may not respond, as in Case 3. Children who have electrolytic imbalance out of proportion to the degree of fluid lost by vomiting or diarrhea should be suspected of having cystic fibrosis of the pancreas.

Pancreatic function in this disease may be normal or only slightly reduced.^{2,3} Respiratory involvement may be the most conspicuous factor in some instances, as in Case 4; other patients have signs of pancreatic insufficiency but almost no respiratory symptoms, and the only abnormal finding in some may be increased concentration of electrolytes in the sweat. It has been estimated that 10 to 15 per cent of patients with cystic fibrosis of the pancreas have little or no deficiency of pancreatic enzymes.³ An infant with meconium

ileus and only partial pancreatic insufficiency has been described in the literature. The degree of pulmonary involvement is the most important factor in determining prognosis in cystic fibrosis of the pancreas. A number of patients with minimal pulmonary disease have lived beyond fifteen years of age.⁷

The first symptoms were gastrointestinal in nature (such as foul-smelling, bulky stools) in twenty-six of the forty-four patients studied at the clinic (Table I); the remaining eighteen patients had respiratory difficulties as the earliest complaints. Of the forty-two patients who had duodenal drainage, only one had normal pancreatic function and five had partial function. Seven patients had normal thoracic roentgenograms. The commonest organisms obtained on culture of the throat and sputum were *M. pyogenes*, *H. influenzae*, *Pseudomonas* and pneumococci.

In Table II it is noted that two patients (Cases 7 and 8) had good nutritional status and yet both had no duodenal enzymes; signs of chronic respiratory disease also were present in Case 8. Evidence of pancreatic and pulmonary insufficiency was noted in Case 9, yet some duodenal enzymes were present. Case 6 represents the so-called classic picture of cystic fibrosis of the pancreas. The only important finding in Case 5 was the abnormal composition of the sweat.

Pathogenesis

Many theories have been considered in regard to the pathogenesis of cystic fibrosis of the pancreas. Such ideas as a deficiency of vitamin A,⁸ a common embryologic origin of the anlagen of the lung and pancreas,⁹ deficiency of secretin,¹⁰ and congenital stenosis or atresia of the pancreatic

ductal system^{11,12} have been discarded as additional knowledge of the disease became available. Farber¹³ offered the concept of "generalized mucoviscidosis," with inspissation of material in the

effective treatment can be instituted. At the present time, there are no medical or surgical measures that will alter the ultimate course of the disease. Since the degree of pulmonary change is

†Detailed discussion in text.

lumina of mucus-secreting organs, plugging of the pancreatic acini and ducts, and obstruction in the trachea and bronchi caused by thick mucus.

The present knowledge that the sweat and salivary glands are involved in cystic fibrosis of the pancreas suggests that all exocrine glands, mucus-producing and others, are affected in the disease. Another hypothesis is that some alteration may occur in the enzymes involved in the production of mucoprotein, which causes an abnormally thick, viscid mucus to be formed.¹⁴ To account for the generalized disease process in cystic fibrosis of the pancreas, several authors have suggested the possibility of generalized dysfunction of the autonomic nervous system.¹⁵⁻¹⁹

Treatment

Further understanding of the pathogenesis of cystic fibrosis of the pancreas is necessary before

the most important factor in prognosis, treatment should be aimed primarily in this direction. An outline of the recommended therapeutic measures includes the following:

1. The diet should be high in calories, with large amounts of protein and simple sugars, such as glucose, and small amounts of fats.

2. Pancreatic extract (pancreatin) should be given with each meal.

3. Antibiotics should be used after the performance of sensitivity tests on organisms obtained on culture of the throat and sputum. Many patients have received penicillin and the tetracyclines for long periods and may harbor organisms resistant to these antibiotics. The use of such preparations as bacitracin, polymixin and cathomycin may aid when resistant strains have developed. Aerosolization of the antibiotics is the most effective

tive method of administration. Aerosolized antibiotics may be particularly effective when combined with a mixture of streptokinase and streptodornase (varidase) and hyaluronidase (alidase). One combination is 2 units of alidase plus 20 ml. of varidase; this, with the antibiotic, may be given as an aerosol in a DeVilbiss No. 40 nebulizer, using 5 ml. of solution for fifteen minutes three times a day. Antibiotics also may be combined with a dilute solution of benzalkonium (Zephiran) chloride for aerosolization.

4. Postural drainage should follow aerosolization three times a day.

5. The use of bronchograms in this disease is contraindicated. Surgical procedures on the lung rarely are indicated because of the generalized pulmonary involvement.

Summary

A study has been made at the Mayo Clinic of forty-four patients who had cystic fibrosis of the pancreas. Four unusual cases are described in detail. A four-year-old girl with cystic fibrosis of the pancreas was admitted because of generalized edema and died from acute cor pulmonale; a three-year-old boy had the unusual association of leukemia and cystic fibrosis of the pancreas; a nine-month-old infant with cystic fibrosis died during a heat wave; a seven-year-old boy had only the pulmonary manifestations of cystic fibrosis of the pancreas, with normal pancreatic function.

These cases emphasize the great variation that exists in the clinical manifestations of cystic fibrosis of the pancreas. Recent studies suggest that the disease is a generalized condition in which all exocrine glands are affected.

The pathogenesis of this disease remains obscure. The extent of pulmonary involvement is the most important factor in the prognosis. Specific treatment is not available at present, but such measures as diet, use of pancreatin, postural drainage and use of aerosolized antibiotics are of some aid.

Determining the Activity of Pulmonary Tuberculosis

Reliability of History, Physical Examination, and Routine Office Laboratory Procedures

RALPH F. WELLS, B.S.
WILLIAM W. STEAD, M.D.
Minneapolis, Minnesota
SHIH H. TSAI, M.D.
Oak Terrace, Minnesota

THE HISTORY, physical examination, and routine office laboratory procedures may prove seriously inadequate in evaluating the patient with an abnormal chest film. By reviewing 203 cases of minimal and moderately advanced pulmonary tuberculosis we would like to emphasize this possibility and suggest the frequency with which it may occur.

Material

Our material consisted of 203 cases of active pulmonary tuberculosis selected from the patients and files of the Minneapolis Veterans Administration Hospital and Glen Lake Sanatorium, Oak Terrace, Minnesota.

Criteria

1. All cases showed demonstrable activity either on the basis of positive bacteriology or by change noted in serial roentgenograms.
2. Only cases with pulmonary tuberculosis were considered; cases with pleural effusion, known extra-pulmonary tuberculosis, and patients who had previous surgical procedures altering the roentgen picture were excluded as were patients with concurrent diseases such as carcinoma, rheumatoid arthritis and pregnancy.
3. Cases were included only if all data were available including initial laboratory data and concomitant chest roentgenogram—all antedating any therapy.
4. The classification of stage of disease followed the NTA standards as outlined in the 1955 edition.¹ Two observers reviewed all films.

Mr. Wells is a senior at the University of Minnesota School of Medicine, and Minnesota Trudeau Society Fellow for 1956; Dr. Stead is chief of the Pulmonary Disease Service, Veterans Administration Hospital, and Dr. Tsai is at Glen Lake Sanatorium.

Cases compatible with the above criteria were studied from the aspect of symptoms,* physical findings,** review of initial chest film plus planigrams when available, WBC and differential, ESR (abnormal 20 mm/hr or more) and comparison of initial and subsequent bacteriology. Initial bacteriology consisted of three Ziehl-Nielsen stained sputum smears (direct or concentrated specimens). Subsequently positive bacteriology consisted of later smears and positive culture.

TABLE I. SOURCE OF CASES—PULMONARY TUBERCULOSIS

	MINIMAL		MODERATELY ADVANCED	
	Hospitalized	Discharged	Hospitalized	Discharged
Mpls. V.A. Hospital	14	29	26	18
Glen Lake Sanatorium	16	37	57	6

Results

Of ninety-six cases of active minimal tuberculosis, 71 per cent were asymptomatic, 71 per cent had no physical findings, 85 per cent had a normal ESR, 93 per cent had negative initial bacteriology and 23 per cent remained bacteriologically negative. Sixty per cent of these patients would have been judged inactive if dismissed when first seen. Only by culture of sputum, or more often gastric contents, or by means of serial films was activity proved.

Of 107 cases of active moderately advanced disease 38 per cent were asymptomatic, 48 per cent had no physical findings, 42 per cent had a

*Symptoms studied included chest pain, cough, hemoptysis, sweats, fever, anorexia and/or weight loss.
**Physical findings studied included rales, rub, dullness and/or weight loss.

normal ESR, and only 23 per cent had positive initial bacteriology. Cavitory disease was present in 75 per cent. Seventy-three per cent with this feature had negative sputum smears.

INDICATIONS OF ACTIVITY IN MINIMAL PULMONARY TUBERCULOSIS

96 CASES

* Physical findings reported in 82 of 96 cases.

Fig. 1.

INDICATIONS OF ACTIVITY IN MODERATELY ADVANCED PULMONARY TUBERCULOSIS

107 CASES

* physical findings reported in 81 of 107 cases.

Fig. 2.

Figs. 1 and 2. Shaded areas indicate present, abnormal or positive findings. Clear areas indicate absent, normal or negative findings.

Of the moderately advanced cases 16 per cent would have been judged inactive by a "routine work-up."

Forty-four cases of far-advanced tuberculosis seen at the Minneapolis Veterans Administration Hospital demonstrated 100 per cent activity at least one sign of activity being initially present in each patient. This suggests that the more severe the disease the easier the diagnosis.

Discussion

At this juncture some comment should be made on skin testing. It is perhaps the most valuable screening test available due to its specificity.

SPUTUM STATUS IN CAVITARY DISEASE - 107 CASES (MODERATELY ADVANCED)

Fig. 3.

SYMPTOMS, PHYSICAL SIGNS, E.S.R. AND SPUTUM SMEARS (ANY OR ALL PRESENT)

Fig. 4.

Figs. 3 and 4. Shaded areas indicate present, abnormal or positive findings. Clear areas indicate absent, normal or negative findings.

Although not diagnostic of active disease, it is of particular value in a population where the incidence of tuberculosis is low or if in an individual the date of conversion is known. Under these circumstances it should alert the physician to the possibility of active disease. With one exception our group was Mantoux positive, bacteria being recovered from this exception.

Our study revealed that over 70 per cent of

the minimal group and almost 40 per cent of the moderately advanced group were asymptomatic. This is not a unique finding. Although the concept of tuberculosis has changed markedly in the past twenty years, the following observation is perhaps still pertinent. Chadwick² in 1933 reported that in 1,500 sanatoria patients an average of ten months elapsed between the onset of vague symptoms and eventual diagnosis and hospitalization. Tsai³ states that in a group of 100 patients with minimal lesions hospitalized at Glen Lake between 1936 and 1948 symptoms were either absent, minimal or hard to evaluate. In this group the presence of hemoptysis in nine patients was the most specific complaint. It then behooves one to question a patient carefully but not to rule out tuberculosis on the basis of negative answers.

As has already been pointed out, the presence of positive physical findings is not appreciably higher than the incidence of symptoms. Morgan and Chadwick² reviewed 2,828 chest films looking for possible tuberculosis. In seventy-nine of 440 x-ray-positive patients, there were no auscultatory findings, eighty-four had decreased breath sounds, as did 271 x-ray negative patients. Of the 440 x-ray positive group 277 had rales, whereas only twenty-five x-ray-negative patients had this finding. It was our experience in this study that, when the examination was performed by a more experienced clinician, positive findings were more frequently noted.

Although the WBC and differential may be helpful in excluding an acute inflammatory process from the differential diagnosis, we found it to be of little direct aid in the diagnosis of tuberculosis. Rich⁴ agrees that there is no characteristic blood picture of diagnostic or prognostic aid in this disease.

It was our experience that the ESR was normal in the majority of minimal cases and in almost one-half the moderately advanced cases. This suggests that the ESR also has limitations in establishing the diagnosis and activity of pulmonary tuberculosis. Westergren⁵ in 1920 suggested the relation of "the suspension stability of the erythrocyte as an index to the activity of pulmonary tuberculosis, specifically, as a diagnostic and prognostic tool superior to temperature studies." Surprisingly, he used as a base line a rather limited group, drawing from the Royal

Navy (Swedish) twelve sailors who were healthy, twenty-three men who were neither ill nor healthy, and thirty-nine men with evident disease. Comparing sixty patients from the Soderby Sanatorium, Stockholm, with this control group he concluded that elevation of the SR (ESR) and the activity of the disease were well correlated. He qualified this by stating that "in cases where normal values are obtained, notwithstanding the diagnosis of pulmonary tuberculosis, it is a benign process." A further qualification was that "at the early diagnosis of tuberculosis the SR must be cautiously determined." In the years that have followed the technique has been popularized, subjected to many revisions and used extensively as a clinical guide. However, Weichsel⁶ in 1924 felt that the value of the ESR had been overestimated. He reported that patients with clear-cut x-ray evidence of disease and positive clinical findings might have a normal ESR, occasionally even in the presence of cavitory disease. Kirby⁷ summarizes contemporary views on the subject stating that the ESR is normal in the majority of patients with minimal disease and that it may be deceptive—being normal in the face of extensive intrabronchial disease and excessively high in the face of a mild pleural reaction.

Our study also re-emphasizes the fact that examination of sputum smears does not constitute an adequate bacteriologic study. Bacteriologic proof of tuberculosis is in large part proportional to the intensity with which it is pursued. Decker⁸ reports that culture of gastric washings yielded positive results in forty-one of fifty-six sputum-negative patients. Needham⁹ reports that at the Mayo Clinic in 1952, 34 per cent of the cultures disclosing *M. tuberculosis* were obtained from material negative on microscopic examination. Kirby and Tsai both stress repeated attempt at culture. The former reports five to fourteen negative cultures before the first positive culture was obtained; the later reports over twice as many positives when six or more gastric studies were done.

Tuberculosis though often classic in roentgen appearance may mimic either a neoplasm or an acute inflammatory process. In our review it was found that a single chest film at best could only suggest the nature and extent of the disease. The exact nature could be determined only by review of serial films. In this regard the value of comparing the present film with any

previous films cannot be overemphasized. Further knowledge regarding the nature and exact extent may be obtained by means of planigraphy. This latter process is of great value in the consideration of cavitory disease.

Edwards et al¹⁰ cite the problems of interpretation of minimal tuberculosis encountered in their review of 7,906 army rejectees followed through the New York City Department of Health. Initial and follow-up films were read in 4,079 cases. It was found that, when these films were read independently, there was such a difference of opinion in the interpretation of the approximately 50 per cent of the films that overlapped that it was necessary to publish two sets of data. The chief discrepancy lay in the interpretation of the nature of the disease. In attempting to evaluate the nature of the process, lesions were classed as exudative, intermediate and fibro-calcific. It was found that the prognosis was most accurately gauged at the extremes. Reissner¹¹, in a review of 469 cases from the Ambulatory Chest Clinic of the New York City Department of Health studied over a five-year-period, concluded that in minimal tuberculosis the chest film provides the most objective criterion for evaluation of the clinical status.

Holman¹² has very excellently reviewed the value of the chest roentgenogram, summarizing its uses and limitations. Specifically, the chest film can locate the lesions and suggest its nature, but only by means of serial films can the activity of the disease be determined.

Summary and Conclusions

The admission, clinical, and laboratory data as well as pertinent subsequent data needed to demonstrate activity were reviewed in ninety-six cases of minimal tuberculosis and 107 cases of moderately advanced pulmonary tuberculosis. The following conclusions were reached:

1. The history, physical examination and most routine office laboratory procedures do not constitute an adequate study of the patient presenting an abnormal chest roentgenogram.
2. Repeated attempts to obtain positive bacteriology by culture technique plus the study of serial films will increase the frequency with which activity may be established.

As Carr¹³ has pointed out, the chief role of the

physician is to have a high index of suspicion which will lead him to study each patient individually and thoroughly.

NEW TB VACCINE

Clinical trials with a promising new tuberculosis vaccine made from human tubercle bacilli killed by irradiation are reported by Dr. Armando Pareja Coronel of Guayaquil, Ecuador, where trials were conducted among 100 children born of parents with tuberculosis.

Of the 100 infants vaccinated, seventy-one have returned to their homes from the hospital and no evidence of active tuberculosis has been discovered. The vaccine was well tolerated and no local reactions were observed, the author states.—*The American Review of Tuberculosis and Pulmonary Diseases*, 75:987 (June) 1957.

Encephalopathies following DPT Inoculations and Pertussis

WILLIAM R. HEILIG, M.D.
Minneapolis, Minnesota

IN 1948, Byers and Moll reported fifteen pediatric cases of encephalopathy following the use of pertussis prophylactic vaccine. The children so studied were from five to eighteen months of age at the time of their affliction with this disease. To all known, these children were of normal intelligence at the time they received pertussis vaccine, and subsequent to inoculation developed the neurologic disturbances which were reported by these two clinicians. In only three of these children was there any family history of neurologic disturbance elicited. In one case, two of three siblings had seizures, and there was an hydrocephalic sibling, and in the third case a younger sibling suffered from febrile seizures. In the evaluation of the material used, there were twelve inoculated with fluid toxoid of the pertussis only; there were two children who had received combined diphtheria-pertussis vaccine (one fluid, and one alum-precipitated); and one child received DPT vaccine, alum precipitated. The sequence of injections did not seem of significance; six cases developed their seizures with the first injection, three with the second, and six with the third. The interval between injection and first neurologic symptoms, usually seizures, varied from twenty minutes to seventy-two hours, and the convulsions, from a few minutes to several days. They varied from mild to severe convulsions and the sensorium changes ranged from irritability to frank coma.

During the acute illness there were six cases seen in the hospital, five showing increased spinal fluid cell counts and with increased total proteins in these cases, ranging from normal to 86 mg per cent. The eyegrounds were normal in all six cases. Two other cases were seen by other clinicians in their acute illnesses and the cell count of the spinal fluid was elevated in only one of these (63 monocytes/cc). Of the fifteen cases, mental fol-

lowup tests showed mild retardation in two, progressive retardation with death in one, eight with moderately severe retardation, and three cases with gross mental deficiency, one of whom subsequently died. Four infants appeared to be mentally normal four to fourteen months after the acute illness, giving approximately 75 per cent retardation in this group of children. Further followup of the four infants who seemed intact may yet show more subtle changes.

Neurologically, thirteen of the fifteen children studied showed persistent convulsions over several years' time. One was eventually felt to have recovered completely, two went progressively downhill and died, nine had severe cerebral damage and had to be considered permanently incapable of competitive living, and three were as yet not followed a sufficient time to determine the final outcome. Eight patients had pneumoencephalograms, six of which showed dilations of the lateral ventricles. The outcome of the electroencephalograms done on ten patients showed six having slow activity with two showing wave and spike discharges and two showing spike foci. No electroencephalograms were obtained on the two patients who died of pneumonia. It is of interest that, while eleven of these children had recurrent seizures, only three of these were cases of cerebral palsy; three others had cerebral palsy without convulsions. Two were also blind; two died; and one was considered normal. This points up a very high incidence of seizures and retardation, but a surprisingly low rate of organic cerebral palsy.

Of a series of twenty-six children suffering encephalopathy due to pertussis over the same period of time, seven died with the acute illness, ten were permanently retarded, six were apparently normal, and three could not be located for followup; this would also attest to the great danger of the disease, as well as the inoculations, in producing encephalopathy. Only three of this

group had recurrent convulsions, perhaps as a result of the high mortality. Studies by other observers up to the time of the article by Byers and Moll would certainly not lead one to expect such a dismal outcome.

Transient, nonrecurrent convulsions were reported by Doull² in three of 496 children given fluid toxoid pertussis vaccine; Taylor³ reported one episode (nonrecurrent) in a ten-month-old child following an injection of fluid toxoid pertussis vaccine. Kentrick and Eldering⁴ reported only one convulsion following pertussis vaccine inoculation in 1,815 children given a total of 9,075 injections. Sako⁵ reported only two transient seizures in 6,000 injections of alum-precipitated vaccine; in 105,000 children immunized to pertussis he was able to locate only four cases of convulsions.

Case Material

With the foregoing material already on record, it would seem of value to report the findings of a series of five cases of encephalopathy following the use of DPT vaccine and five cases of encephalopathy attendant to the disease of pertussis itself. These cases represent the turnover of a five-year survey at the University of Minnesota Hospitals, Department of Pediatrics. These cases have been selected only by virtue of their disease, and represent the entire group of such cases in the period of time. They were all subjected to a standard convulsive workup, including blood sugars, calcium, phosphorous, blood urea nitrogen, skull x-rays, electroencephalograms, and, in several cases, pneumoencephalograms. The results of these

TABLE III

Case	Type of Seizure	Pneumoencephalogram	Electroencephalogram
M.R.	Grand mal with mental retardation	Mild frontal atrophy at age of nine months.	Diffusely abnormal with generalized slow high voltage waves, frontal spikes, and spike-wave discharges
C.G.	Generalized tonic and left focal (arm, leg, face)	Normal at 4 years and 10 months.	Diffusely abnormal with generalized slow, hi-voltage waves of 1-1½ per second frequency
D.N.	Diffuse tonic and myoclonic	Normal at 3 years and one month	Normal record obscured by diffusely scattered slow, hi-voltage waves.

I.M.	Tonic-clonic, diffuse, mild	None done	Diffusely abnormal with 2-4/sec. hi-voltage slow waves and wave/spike abnormalities in all areas

studies and the conclusions drawn from them follow.

Analysis of Cases Due to Vaccination

Five cases of encephalopathy followed the use of alum-precipitated triple vaccine (DPT). All the patients in this group were under eight months of age. There were four boys and one girl. There seemed to be no definite likelihood of any one injection in the series causing encephalopathy any more than any other. Three had their reaction after the first injection and two followed the second injection. All of the cases developed their fateful reactions within twenty hours after the specific injection. They were almost uniformly accompanied by temperatures of 103 degrees rectally, or higher. The reaction then proceeded to the convulsive state within varying periods of time. It is of interest that none of these children had had febrile seizures prior to this, a fact which would tend to suggest that these reactions were not in the nature of a fever convulsion (Table II).

All of these children had major convulsive phenomena of the grand mal type; one had a focal left-sided seizure and one had additional components of petit mal attacks (Table III).

In only one case was there a family history of either febrile or epileptic seizures. This boy (M. R.) had a paternal uncle who had seizures and was retarded.

A review of the birth histories revealed three apparently normal deliveries at term, one hard, fifty-six-hour labor, in which the local physician stated that the baby was in such bad shape that

he was not expected to live. Despite all these factors, however, all of these children were considered by their parents to have progressed normally, up to the time of the disease following their pertussis vaccinations.

Electroencephalograms were done on all five of these children at the time of their initial hospital study with the results seen in Table III. In brief, abnormal records were all characterized by marked slowing to the 1½-4/sec. activity with marked increases in voltage. These findings were generalized, and in three cases there were wave and spike complexes similar to a petit mal variant. Only one case (E. H.) had a normal electroencephalogram (Table III).

Pneumoencephalograms were done in three of the five cases. Two were reported as normal and one showed atrophy of the frontal regions of the brain (Table III).

The treatment of these patients was primarily anticonvulsant and, in general, the most valuable drugs were found to be Mysoline and Mebaral in combination; in one instance, Mebaral was satisfactory alone, and in one instance Mebaral and Dilantin were used without Mysoline (Table V). In three instances there were marked reduction of seizures, but in two cases no form of therapy was able to produce any notable improvement. Three patients were recommended for state hospital placement because of retardation and one was put in a special class at school. Only one patient of the five is at present judged to be normal in followups after the initial disease varying from nineteen to seventy-one months (Table

TABLE V

Case	Trend of Seizures (Good or Bad)	Clinical Problems	Best Seizure Medications	Prognosis
M.R.	Bad—little improvement	Delayed speech slow development	Mysoline Mebaral	Poor
C.G.	Bad—cyclic remissions	Delayed, thick speech, obvious progressive deterioration	Mysoline Mebroin	Poor
D.N.	Bad—cyclic remissions but generally frequent	Slowing some, is probably slow	Mebroin	Guarded
E.H.	Good	Initially dull, now is normal to all signs	Mysoline Mebroin	Fair
I.M.	Good	None	Mebaral	Good

IV). In general, then, the prognosis for these children was very poor as far as normal life and job expectancy is concerned.

Analysis of Cases following Pertussis Infection

In the same five-year period as the preceding cases, there were also five cases of pertussis with accompanying encephalopathy and convulsions. These children formed an older age group and the seizure disorder was as severe or more so in the pertussis cases as in the vaccine cases. The age at onset varied from one and one half to eight years; the interval between the acute illness and evidence of convulsions or encephalopathy varied from six months to one year. In only one case was there any previous history of any prophylactic pertussis vaccine given, and in this case the boy had had three injections in the first year of life of alum-precipitated DPT (Table VI). Electroencephalographic studies on the first hospital study showed three diffusely abnormal tracings with two normal tracings. As in the vaccine cases, they showed marked slowing and, in certain areas, wave-and-spike complexes could be found (Table VII).

A study of the seizures revealed that all these children also had major motor seizures, and in four out of five cases these were very severe. Despite this, however, on therapy, two of these children stopped having seizures, and the other three showed marked improvement (Table VII).

Followups were made from one and one half to nine and one half years after the initial encephalopathy (Table VIII), and it was found that three children still had seizures although much improved; three were definitely mentally retarded in

TABLE VII

Case	Type Seizure	Intensity	EEG Reading	PEG	Subsequent Course
J.E.	Major motor diffuse	Severe but infrequent	Diff. Abn. and rt. centroparietal focus	0	Seizures stopped in 6 years, with medication now discontinued.
D.P.	Major motor and left sided focal	Markedly severe and frequent	Diffusely abnormal slow, high voltage	0	Seizures stopped at age 10 years, medication discontinued at 9 years after first seizure, 6 years after starting.
T.S.	Tonic, general	Severe	Normal	0	Seizures almost stopped on medication. (One in last year)
A.H.	Hyparrhythmia or similar to P.M. variant	Severe	Diffuse and total dysrhythmia with hivolt, wave and spike complexes.	0	Marked improvement in seizure and mental attitude
R.B.	Diffuse myoclonic spells, similar to P.M. Variant		Normal	0	Much improved seizures, both frequency and severity on medication.

contrast to their pre-ictal state. There were no cerebral palsies among this group (Table VIII). Only one child had a pneumoencephalogram (T. S.) and that was normal.

For evaluation of the cases from the standpoint of seizure control, medications of choice, and the prognosis for these children, see Table VIII and IX. It will be noted that, while there were three cases of retardation, the seizure control was good in all five cases, in contrast to the vaccine group. Mebaral was the drug of choice in two cases, Mysoline in one, Tridione in the third, and Tridione plus A.C. 695 in another. Two patients are considered to be essentially normal, two are likely candidates for state hospital care, and one, though retarded (A. H.) has made such remarkable progress in the one and one half years following his encephalopathy that judgment had best be withheld at present. It is possible, therefore, that three of five cases of pertussis encephalopathy will show a satisfactory recovery and certainly a definitely encouraging control of their seizures.

Mechanisms of Production of Pertussis and Pertussis-Vaccine Encephalopathy

In the case of the encephalopathy produced by the active pertussis infection, it is not all difficult

to conceive of the nerve cell damage which could result from endotoxins and exotoxins acting directly on the cortical and nuclear cells. In addition, the likelihood of the severe cerebral congestion produced by coughing probably makes anoxia and hemorrhage an additional hazard. An interaction of all forces in severe cases of pertussis may be responsible for the marked encephalopathy which results.

In the case of the vaccine encephalopathy, the picture is not so clear. Many of the toxins, if not the majority (both exotoxins and endotoxins) are probably destroyed by heat and preservation; this was demonstrated by Berdet and Gengou.⁶ This would cast serious doubt on the theory of direct toxin effect in the case of pertussis vaccine disease. The other major hypothesis is that an antigen-antibody response is established, resulting in a destructive neutralization phenomenon, perhaps with the liberation of an histamine-like substance. However, this probably would not account for the cases in which the baby is getting his first injection, and by virtue of his age has likely had little chance to encounter and react to a sufficient dose of *H. pertussis* organism to establish a sensitization. The studies of Byers and Moll,¹ when reviewed in the light of this present paper, would make one wonder whether the preparation of the

vaccine (fluid vs. alum) is of any very great significance, or whether there must not be some substance, not heat-labile, which is present in pertussis vaccine of all types, and which offers potential danger no matter what the product.

Relative Pertinence of Sex Incidence

As noted in the excellent work of Byers and Moll, there is an apparently definite sex predilection among all males for both vaccine and pertussis encephalopathy—nine of our current ten cases were boys. In this small group of patients, the sequence of the involved injection was not found to be of any significance. The electroencephalographic findings in both types were similar, and the small number of air encephalograms makes that measurement invalid. In comparison, the two diseases produce very similar clinical and laboratory pictures.

Discussion

Arguments in Favor of Continuing with Prophylactic Pertussis Inoculation.—Despite the obvious dangers inherent in any form of pertussis vaccine, it seems that there are equal, if not greater, dangers in not using the vaccine. In consideration of the hundreds of thousands of pertussis inoculations of all kinds given to children under age five each year, the risk is not as great as it might seem. One must remember that just a few years ago pertussis was probably the greatest infectious cause of infant death in the first year of life. That was far more evident to the practicing pediatrician than is the pertussis encephalopathy which seems foreign to the personal experience of most pediatricians. Despite frequent toxic and febrile reactions, it is unusual to find a pediatrician who has had a case of this disease among his patients; this is probably also true among the family physicians throughout the country. For this reason, it would seem feasible to continue at present with the pertussis inoculation program. It would be wise, however, to keep the following considerations in mind when vaccinating for pertussis:

1. Consider carefully the child who has a history of febrile seizures, especially if severe. Be prepared to prevent this complication if the vaccine is to be used.

2. In the presence of a history of severe reaction to previous immunizations (tetanus, et cet-

era), it may be wise to split up the doses, if not abandon the procedure entirely.

3. In the presence of pre-existing cerebral damage, the danger of an additional insult is possible with further loss of mental and neurologic potentiality.

4. There seems little evidence as yet to suspect that a family history of seizures would greatly enhance the danger of encephalopathy from pertussis vaccination. Livingston,⁷ in his recent book on convulsive disorders in childhood, finds no specific reason to deny the average epileptic child the benefits of immunization.

Conclusions

This is the report of five cases of pertussis encephalopathy and five cases of encephalopathy following vaccination against pertussis with alum-precipitated DPT vaccine. It is noted again that this disease is more prevalent in male children, closely resembles the natural disease, results in a high incidence of epilepsy and mental retardation, and produces a high degree of cerebral dysrhythmia. At the present time it seems likely that, despite the inherent dangers of vaccination, the danger of nonvaccination is potentially more hazardous. The demonstration in this paper of DPT vaccine cases and the prior reports of fluid toxoid encephalopathy further complicate the concepts of the etiology of this affliction. Several considerations to be made before pertussis vaccination is begun are elaborated. It would seem that severe reactions, especially pre-ictal reactions, noted with first or second pertussis inoculations, should seriously merit consideration for the discontinuance of the series.

Addendum

Since submission of this report four additional cases of DPT reactions with major seizures have been submitted to the author in the Twin Cities area. In addition, one case of myoclonic epilepsy beginning with pertussis infection associated with convulsions has been encountered.

Of the four cases showing convulsions and clinical encephalopathy following the first DPT shot, two have been severely affected (one, who is a hopeless spastic, received her shot at age seven years; one, who is now retarded and epileptic, received her shot at three months). One child is

(Continued on Page 556)

Gastric Ulcer

ARTHUR W. IDE, JR., M.D.
Minneapolis, Minnesota

THE CONTROVERSY as to whether a gastric ulcer should have medical or surgical treatment is a continuing one. The malignant propensity of gastric ulcer is particularly important, but also of importance in the comparison of medical versus surgical results are mortality and morbidity statistics computed for each type of treatment. Recent experience of the Nicollet Clinic will be presented.

Review of Literature

There is, on the one hand, the large experience of the Mayo Clinic,¹ where it is reported that 80 per cent of all small gastric ulcers treated medically had unsatisfactory results; 33.8 per cent of these medically treated cases eventually had surgical treatment. Strode² believes that there is little or no place for medical management for gastric ulcer. Martin and Lewis³ in England believe that the natural course of gastric ulcer is not influenced by medical treatment, which is dictated by the nature of the disease rather than the disease being altered by medical treatment. Their experience indicates that gastric ulcers of long standing rarely heal.

On the other hand, are those^{4,5} who claim that in only 1 or 2 per cent of carefully controlled medically treated cases will malignant lesions be included and that this medical error is within the range of surgical mortality. Brown at the Cleveland Clinic,⁴ for example, cites an incidence of 1.1 per cent of carcinoma in 715 cases of gastric ulcer. This is an unusually low figure. The Mayo Clinic¹ reports this incidence as 10.4 per cent in their group of 414 benign-appearing ulcers, which were observed for at least five years. It is difficult to assess this figure from the Lahey Clinic report,⁶ which concludes that "a month or less of intensive medical management in many cases of gastric ulcer is justified." It is interesting that, despite insistence on the value of medical treatment in selected cases, the percentage of patients with

gastric ulcer operated on at the Lahey Clinic has risen from 40 per cent in 1948 to 58 per cent in 1953. At the Mayo Clinic this surgical rate has remained between 60 and 70 per cent for many years. Also, at the Mayo Clinic⁷ in 550 cases operated upon between 1938 and 1942 with a preoperative diagnosis of benign gastric ulcer, 13 per cent were found to have malignant lesions. Wangenstein⁸ gave this incidence at 10 per cent. Ransom⁹ found an incidence of microscopic malignancy in 10 per cent of operative specimens, and in none of these was the diagnosis made by the operator at the time of surgery.

One of the most striking features of malignant gastric ulcer is that five-year survival rates are higher than those for other types of gastric carcinoma. In the Mayo Clinic cases⁷ of preoperatively diagnosed benign but pathologically proved malignant ulcers, 43.5 per cent lived five years or more following operation. In Ransom's series, 41 per cent of the cases in this category surviving operation lived five years or more. Therefore, this is a particularly fruitful field for surgical therapy in the usually dismal picture of stomach cancer.

Entirely aside from the matter of malignancy in the comparison of medical versus surgical results in gastric ulcer are the over-all figures for mortality and morbidity. The best surgical mortality figures are between 1 and 2 per cent. In the Mayo Clinic series of 414 patients treated medically,¹ only 20.5 per cent were considered to have had satisfactory results. On the other hand there are frequent assertions in the literature¹⁰ that at least 90 per cent of the surgically treated patients have satisfactory results. It is well known that morbidity and mortality following gastric resection for gastric ulcer are much less than those following gastric resection for duodenal ulcer.

Material

The material to be presented is from the Nicollet Clinic and includes those cases which

were originally diagnosed as benign gastric ulcer. This series extends from 1943 through 1956 and includes only those cases in which a definite diagnosis was made. Cases which were diagnosed as "possible" or "probable" without additional confirmation by the roentgenologist were excluded. A large percentage of the patients were from out of the city, so that much of the follow-up was done by questionnaire.

There were fifty-six cases in all, eighteen of which were treated medically and thirty-eight treated surgically, thus giving a surgical rate of 68 per cent. The ages of the patients varied from twenty-nine to seventy-five. There were thirty-five men and twenty-one women, or roughly a two to one proportion. A total of twenty-six ulcers were located along the lesser curvature, whereas none were along the greater curvature. The remaining ulcers were located as follows: pre-pyloric, twelve; pyloric, eleven; cardiac, four; body, three. The ulcers which were subsequently found to be malignant were located as follows: cardia, two; mid lesser curvature, two; pylorus, one. No ulcers either benign or malignant were located along the greater curvature. A benign ulcer of the greater curvature is rare.

Diagnosis

The initial x-ray diagnosis in the surgical cases was correlated with the pathologic diagnosis (Table I). There were twenty-eight benign diagnoses made by the roentgenologist, compared with twenty-five benign and three malignant pathologic diagnoses. There were five cases described by the roentgenologist as probably or possibly malignant; all of these five were benign pathologically.

Gastroscopic examinations were done in nine patients, in several of whom more than one examination was done. It should be remembered that these nine patients were those extremely difficult to diagnose and were referred to the gastroscopist for this reason. There were three cases diagnosed benign by the gastroscopist; one of these was malignant by pathologic examination.

TABLE II. SURGICAL PROCEDURES DONE

Billroth II	25
Billroth I	6
Transthoracic gastric resection.....	3
Transthoracic exploration	1
Gastroenterostomy	1
Local excision	1
Abdominal exploration	1
Ligation of arteries	1
Vagotomy and re-resection	1

This was the only serious error made by gastroscopic examination. There were four cases diagnosed malignant by gastroscopic examination three of which were benign and one malignant by pathologic examination. There were two indeterminate cases, both of which were benign by pathologic examination. It may be stated in summary that gastroscopic examination was in general of considerable help, but certainly not infallible.

Surgical Results

Table II illustrates the various surgical procedures done. The three transthoracic gastric resections were done for ulcers at the cardia. The one gastroenterostomy was done in 1943 for a large perforating posterior ulcer near the lesser curvature. There were multiple adhesions, and resection was impossible in the opinion of the surgeon. The one local excision done was also for a suspicious ulcer at the cardia. Symptomatic results in this case have been excellent, as determined by two year follow-up. There was one patient with profuse hemorrhage in persistent shock, who was taken to the operating room where the left and right gastric arteries were ligated as an emergency procedure. Several days later he withstood gastric resection successfully. Vagotomy and re-resection were done in a case of gastrojejunocolic fistula following resection.

There were forty surgical procedures done on thirty-eight patients with one surgical mortality, or a patient death rate of 2.6 per cent. This one mortality occurred in a sixty-three-year-old man, a known cardiac patient, who was operated on as an emergency procedure because of severe hemorrhage. He died the day of surgery from cardiac complications. If one excludes emergency procedures, then, the surgical mortality in the elective cases was zero.

There were five serious long-term surgical complications. The first was a stomal ulcer with subsequent slight to moderate hemorrhage following the single gastroenterostomy done for benign gastric ulcer in this series. It is the consensus of the literature that gastroenterostomy is

ery seldom followed by stomal ulcer when this procedure is done for benign gastric ulcer. This is in contrast to the situation when this procedure is done for duodenal ulcer.¹ The second long-term complication was the gastro-jejuno-colic fistula following gastric resection. This occurred in a forty-three-year-old woman with a large gastric ulcer on the posterior wall near the lesser curvature penetrating into the pancreas. I am unable to find a report in the literature of this complication following gastric resection for benign gastric ulcer. The Cleveland Clinic published a report of a stomal ulcer following gastric resection and Billroth I procedure done for benign gastric ulcer, and considered that complication a rarity.¹¹ Certainly a stomal ulcer progressing to a fistula after resection for benign gastric ulcer is an extremely unusual complication. Even more remarkable is the rapidity with which this fistula occurred, only three months following the original resection. At re-operation at this three-month period, re-resection and vagotomy were done. A huge marginal ulcer measuring 10 cm in diameter was removed at the site of the fistula. This patient is well two years following this second procedure. Unfortunately, no gastric acid determinations were done.

A third serious long-term complication in one patient is a recurrent empyema following transthoracic resection, for which the patient refuses further surgery. A fourth complication was diagnosed as recurrent aspiration pneumonia following a transthoracic resection of the upper two-thirds of the stomach and the lower inch of the esophagus for a large suspicious ulcer at the cardia pathologically proved benign. The normal gastroesophageal pinch-cock mechanism has been destroyed in this patient, thus allowing regurgitation of stomach contents including bile into the throat and subsequent aspiration. It is hoped that elevation of the head of this patient's bed during the night will prevent further episodes. The fifth complication is severe postprandial gastrointestinal distress in an emotionally unstable woman. This complication has been diagnosed elsewhere as a dumping syndrome. This series is remarkably free of dumping syndromes, as I think is probably the case generally for resection for benign gastric ulcer, although a Mayo Clinic report suggests the contrary.¹² The low acids encountered in this disease make it possible to remove less stomach without fear of marginal

TABLE III. FOLLOW-UP OF PATIENTS OPERATED ON FOR BENIGN GASTRIC ULCER

Good	24

Poor (stomal ulcer: posterior gastroenterostomy)	1
Dead (unrelated causes)	2
Total	30

ulceration. It has been repeatedly demonstrated that the incidence of dumping syndrome is less in those cases where a more conservative gastrectomy is done.

Table III appraises the surgical results. The two patients listed as fair probably will be good. In one of these, recurrent empyema and, in the other, recurrent aspiration pneumonia occurred. In essence, then, approximately five out of six surgical patients have had good results. If one excludes the patients dead of unrelated causes and the surgical results of procedures other than resection, the results are good in more than 90 per cent of the cases.

There were four patients with malignant ulcers who were treated surgically. One was explored transthoracically. This patient had been treated elsewhere for two years with the diagnosis of benign gastric ulcer. Exploration at our Clinic revealed a nonresectable carcinoma, and the patient died of recurrent hemorrhage three weeks following surgery. The second case has been mentioned previously as having been diagnosed gastroscopically and also roentgenologically as a benign ulcer and was observed for almost one year in our Clinic. This patient eventually had an operation because of abdominal cramping, which surgical exploration revealed to be small bowel obstruction from a nodule metastatic from a malignant ulcerating lesion of the stomach. The third patient was operated on with a diagnosis of benign gastric ulcer. Resection was done and malignancy proved by microscopic examination. This patient died of generalized metastases three and a half years after surgery. The fourth and last patient in this group was a lady in whom a benign diagnosis was made on upper gastrointestinal x-ray. One month later, severe upper gastrointestinal hemorrhage occurred with a resultant hemoglobin of 6 grams. At that time roentgenologic diagnosis was probable malignant gastric ulcer near the cardia. A Billroth I resection was done. The lesion was carcinoma, and there were metastases in the regional lymph nodes. This patient is living and well three and a quar-

ter years later. A summary of this series reveals, therefore, only two patients with preoperative diagnoses of benign gastric ulcer who had resections, so that it is not possible to determine whether the relatively good five-year survival results reported elsewhere are confirmed by our series.

Medical Results

The results in the medically treated cases are summarized in Table IV. Thirteen of the eighteen medically treated patients were observed for periods of one year or more. Of these there were eight good results. Seven of these cases were observed from five to eleven years. Three were observed four years. One case with a dramatic and unfortunate result was observed only six days. This is the case of a woman, thirty-three years old, approximately five months post partum. Her stomach roentgenogram was diagnosed as showing a benign gastric ulcer on the lesser curvature. Six days later she died suddenly. A coroner's postmortem examination revealed what appeared grossly to the pathologist as a benign gastric ulcer. Microscopic examination, however, revealed adenocarcinoma with metastases in the regional abdominal and mediastinal lymph nodes. There were also diffuse lymphatic metastases in the lungs.

There was a total of five patients in this group who had medical management and subsequently had cancer. The first case is that of the thirty-three-year-old woman just described. The second is that of a patient who originally had a diagnosis of benign gastric ulcer, but approximately one month later this diagnosis was changed to that of probable malignant ulcer. Surgery was advised but refused by the patient. This patient was operated on elsewhere five years later, and carcinoma of the stomach with metastases was found. He died one year later, six years after the original diagnosis at the Nicollet Clinic. The remaining three cases in this group have already been discussed among the surgical cases.

In summary, there were five cases of gastric

TABLE V. INDICATIONS FOR SURGERY

	Primary	Secondary
Intractability and recurrence	17	2
Carcinoma	4	
(suspect)	4	
Hemorrhage	5	13
Obstruction	7	
Perforation	1	
Total	38	

ulcer proved pathologically malignant at surgery or autopsy in this series of fifty-six cases of gastric ulcer originally diagnosed benign at the Nicollet Clinic or in one of several Minneapolis hospitals. This is a 9 per cent incidence of malignancy in this series.

Table V presents the indications for surgery in this series. It is obvious that intractability and recurrence represent the most frequent complications of gastric ulcer and therefore the most common indications for surgery. This was the primary indication for surgery in seventeen of the cases. Carcinoma was next with eight either overt or suspected carcinomas. Hemorrhage and obstruction were less frequent. There was one perforation.

Discussion

In summary, it appears that formulation of hard and fast rules from data such as those given here is difficult. In 68 per cent of the cases operations were done, which is approximately the same percentage reported in much larger series from the Mayo Clinic and the Lahey Clinic.

That many gastric ulcers heal is unequivocal. Small, undisputably benign ulcers of short duration should perhaps have medical management if one feels that the risk of malignancy is less than the risk of operative mortality. The longer the duration of a gastric ulcer, however, the more probable are complications such as hemorrhage, obstruction, and perforation, as well as malignancy. Recurrence, persistence over three to six weeks, extensive penetration or large diameter, roentgenologic or gastroscopic appearance indicating malignancy, achlorhydria, difficult follow-up, or suspicious location—any of these indications should dictate immediate surgery. The surgical mortality rate in this disease is low, mainly because of the ease and safety of closing the duodenal stump in gastric as opposed to duodenal ulcer cases. Malnutrition, anemia, stomal ulcer, and the dumping syndrome are mild or infrequent postoperative complications in gastric ulcer cases. This is true because of low acids and the

possibility of doing a less extensive resection than is necessary for duodenal ulcer cases. Although the Billroth I operation is condemned by some,^{6,10} for duodenal ulcer, this procedure is very satisfactory for gastric ulcer.

Conclusions

1. Some gastric ulcers of short duration are amenable to medical treatment.
2. Surgery is indicated in those cases with obvious complications, where malignancy is suspected, or where medical treatment of not longer than three to six weeks' duration is ineffective.
3. The increasing incidence of surgical treatment of gastric ulcer is validated by the results which are good in over 90 per cent of the cases.
4. The results of surgical therapy for malignant gastric ulcer are better than for other types of gastric carcinoma.

EARLY DETECTION OF CANCER MAY NOT BE EARLY ENOUGH

In some types of cancer, the earliest detectable diagnosis may not be early enough—in fact, some cancers may be widespread even when still too small to recognize by present diagnostic methods, according to a report (May 1, 1957) in *The American Journal of Roentgenology, Radium Therapy and Nuclear Medicine* by Drs. Harold Tivey and Vincent P. Collins, both of Houston, Texas.

Drs. Tivey and Collins also expressed some misgivings and doubt about some claimed "five-year" cures in cancer treatment, where cure is assumed in some statistical reports if the cancer does not reappear within the five years of treatment.

"It would appear that only in those diseases which have a very short duration does the five-year survival have a reliable prognostic significance for the individual," the two scientists added.

"There is some small volume of data collected to indicate that the earliest detectable diagnosis may not be early enough. It seems possible that some cancers may disseminate widely at a time when they are too small for clinical recognition by any of our present methods," they continued.

"A more complete analysis, to include 'cures,' is needed. This cannot be accomplished reliably until we know how early tumors metastasize. With detailed knowledge of tumor doses necessary to eradicate local disease, we could then calculate with some assurance the expected effect of early diagnosis," Drs. Tivey and Collins went on.

The two Houston scientists then discussed usable criteria of cure for cancer based upon the "natural history" of the disease.

"Since the five-year cure rate will consistently overestimate the proportion of patients cured, this proportion, when evaluated in terms of the natural history of disease . . . will result in substantially lower proportions of cures," they pointed out.

In group statistical analysis, the concept of a disease's natural history has the overwhelming advantage of enabling the investigator to predict the ultimate outcome of all his cancer patients being treated, the Baylor University investigators went on.

They added their belief that for the individual patient, too, separate from the group evaluation, the criterion for cure must be based upon the natural course of the patient's malignant tumor.

Other suggestions advanced by the Houston researchers:

. . . Clinical staging of disease, where the extent of cancer is specified in certain "stages," may be in some instances a reflection of the inherent growth rate of the tumor rather than the patient delay to detection of the tumor.

. . . In one group of patients with stomach cancer, surgically operated patients had typically twice as long patient-delay as inoperable patients, i.e., those patients for whom surgery would have done no good. This is more readily explained if longer persistence of symptoms implied a more slowly growing tumor.

. . . By determining the growth rate of a cancerous tumor and then treating it, if it did not recur within the time required for it to grow, this simple criterion could prove a useful definition cure for the individual patient.

Present-day Concepts of the Treatment of Ulcerative Colitis

LOREN E. NELSON, M.D.
Saint Paul, Minnesota

THE treatment of chronic ulcerative colitis has been a perplexing problem for physicians and surgeons alike as long as this condition has been known as a clinical entity. Despite the many remarkable advances of modern medicine, ulcerative colitis continues to present a challenge to investigators. Its etiology is still unknown, and no truly specific treatment has yet evolved. Nevertheless, it is possible to manage the great majority of these patients successfully and permit them in most instances to lead a normal life.

Ulcerative colitis has been known as a clinical entity for less than eighty years. Sir Samuel Wilks¹ in 1875 first distinguished this condition from the large group of other enteric maladies with which it had until then been confused. Since early workers first focused attention on ulcerative colitis, both medical and surgical treatment of the disease have passed through many interesting phases as medical knowledge grew. To understand fully the modern concept of therapy of chronic ulcerative colitis, it is instructive to review briefly the development of medical and surgical treatment and their integration through the years.

Medical Treatment

Conservative treatment of ulcerative colitis at first consisted of the use of a wide variety of medications which were used for rectal irrigations and instillations. The first real advance in medical therapy came in 1924, when Bargaen² described experimental studies on the etiology of ulcerative colitis. Smears were taken from the rectal mucosa of ulcerative colitis patients and Gram-positive diplococci were isolated in 80 per cent of the cases. This seemed conclusive evidence that ulcerative colitis is an infectious process, so a vaccine was prepared for the organism which had been isolated. The Bargaen vaccine was used in the treatment of this disease, often with satisfactory results, until the advent of Neoprontosil in 1938. The results obtained through the use of this drug

were as good or better than those obtained with the vaccine.^{3,4}

From that time onward, with the development of various sulfonamides and antibiotics, they have all been utilized for the treatment of chronic ulcerative colitis.

Bargaen⁵ in 1949 introduced in this country a drug called salicylazosulfapyridine. Commercially, this is known as either Azulfidine or Azopyrine. It is an azo compound between salicylic acid and sulfapyridine. Because this drug is an acid azo compound, it has an affinity for connective tissue (including the submucosa of the colon), and aminosalicic acid and sulfapyridine are liberated gradually. This drug has been used extensively in the treatment of ulcerative colitis with encouraging results and no serious side effects. The newer broad spectrum antibiotics have found limited usefulness in the treatment of ulcerative colitis. They are used chiefly for the acute fulminating form of the disease in which superimposed secondary infection probably plays a large role.

In 1950, cortisone and ACTH were first employed for the treatment of ulcerative colitis.⁶ It appeared that most patients got a prompt remission with disappearance of the acute inflammatory reaction of the colon, a feeling of well being, improved nutritional status, reduction of bloody stools, and increase of appetite. The hormones bring about a remission of the disease but, as is the case with all other forms of treatment, the fundamental disease process remains. Flare-ups commonly occur upon withdrawal of the hormones. Probably the major drawback in the use of the hormones is that certain serious complications have occurred following their administration. These include clinically unrecognized perforation of the colon, as well as the more widely known complications of steroid therapy.

Some evidence has been gathered that psychiatric abnormalities play a role in the etiology of ulcerative colitis. Groen⁷ and Morrison⁸ reported excel-

lent results through the use of psychotherapy for ulcerative colitis patients. It has been noted that some patients with this disease who have received electric shock therapy showed definite improvement. It is evident from the foregoing that the search for a specific treatment for ulcerative colitis has been wide and varied and, as yet, not truly successful.

Surgical Treatment

The surgical treatment of ulcerative colitis has also passed through several phases as knowledge has grown. The first operations, cecostomy and appendicostomy, were done for the purpose of making possible more thorough irrigation and injection of medications to bathe the diseased mucosa. The next procedure devised was that of ileostomy. It became apparent that diversion of the fecal stream would be of value to put the diseased colon at rest. This operation was not widely accepted until the early 1920's when it began to gain in favor. For the next twenty years this was the operation of choice for ulcerative colitis, but it was evident that something was lacking in this form of treatment. Few patients with ileostomy improved sufficiently to have an anastomosis made, and many gradually became worse and died.

Sir Arbuthnot Lane⁹ was the first to attempt a series of colectomies for ulcerative colitis. He did this with remarkable success, performing fifty-two colectomies between 1909 and 1913, with a mortality of only 10 per cent. This operation was done sporadically by various surgeons in the ensuing years. These colectomies were done in several stages. MacGuire¹⁰ in 1940 described the first one-stage total colectomy and abdominoperineal resection. From this time and for over ten years, the usual surgical practice was to do a preliminary ileostomy followed in a few months by a colectomy. The rectum was usually saved with the hope of restoring continuity later by means of an ileoproctostomy. Experience demonstrates that, unfortunately, this latter procedure was rarely successful because of subsequent flare-up of disease in the rectum. Most surgeons have come to agree that it is useless to try to preserve the rectum when surgery is necessary for ulcerative colitis. More and more when the patient's condition permits, one stage ileostomy, colectomy, and resection of the rectum is done.

Results of Treatment of 114 Cases of Ulcerative Colitis

A study was made of cases of ulcerative colitis from our own practice. Only those cases were selected for review that had been personally

TABLE I. RESULTS OF TREATMENT WITH AZULFIDINE

Results	Number	Per Cent
Excellent	34	36.9
Good	40	43.5
Poor	13	14.1
Reactions	5	5.5
	92	100

treated by us and then followed up thoroughly enough to yield some real information. Cases that were seen initially in the acute fulminating stage and operated upon soon afterward are not included, as no other treatment could be employed.

A group of 114 patients with adequate follow-up was chosen for review. Of this group, ninety-two cases were treated within the last five years. Azopyrine has been used during this period in our practice as the treatment of choice. The remaining twenty-two cases were treated before the advent of Azopyrine.

The incidence of ulcerative colitis was fairly evenly divided between the sexes; 55.3 per cent were females and 44.7 per cent males. The age of onset of the disease varied from two years to seventy-three years. The incidence in children was a little surprising. In the Azopyrine treated group alone, thirteen of the ninety-two patients were below sixteen years of age at the onset of symptoms. The symptoms of the disease in 108 cases where they were recorded were as follows:

Bleeding, 91.7 per cent
Diarrhea, 53.7 per cent
Constipation, 13.0 per cent
Constipation and diarrhea, 2.8 per cent
Abdominal distress, 31.5 per cent
Passage of mucous, 23.1 per cent

Bleeding was the sole symptom in 24.1 per cent of the cases. It is interesting to note that about 44 per cent of all the cases did not have diarrhea. Their stools were either normal or constipated. The results of treatment with Azopyrine are shown in Table I. Excellent or good results were obtained in 80.4 per cent. The response was considered excellent in cases with prompt remission of symptoms and healing of the rectal mucosa demonstrated by proctoscopic examination within one month.

Those classified as good usually had a symp-

TABLE II. COMPLICATIONS IN 26 OF 114 PATIENTS (22.8 PER CENT)

Complication	Number	Per Cent
Polyps	12	10.6
Abscess	9	7.9
Perforation	3	2.6
Erythema Nodum	3	2.6
Fissure	2	1.7

Stricture	1	.9
Ileitis	1	.9
Gangrenous Pharyngitis	1	.9
Obstruction	3	2.6
Fecal Fistula	1	.9

tomatic remission in the first few weeks of treatment, but three or four months elapsed before real healing was evident on proctoscopic examination. Reactions to the medication severe enough to necessitate discontinuing the drug occurred in 5.5 per cent of the cases. These consisted of nausea, drug rash, or fever. Seven other patients complained of nausea temporarily, but this subsided and they were able to continue the treatment.

Cortisone was used in addition to the Azopyrine in eight patients (8.7 per cent). Two of these had had an initial excellent and three an initial good response to Azopyrine with later unsatisfactory response. The other three never did have a good response to Azopyrine. Enough time has not elapsed for evaluation of the results of cortisone treatment in this small group of patients, although it does seem to have been of value to a few.

Complications observed in the entire group of 114 patients are recorded in Table II. The frequency of perirectal abscess in these patients is worthy of comment. This complication was observed in nine of the 114 patients. All but one of the patients complained of diarrhea as one of their major symptoms. The inference is that diarrhea resulted in anal cryptitis which, in turn, went on to cause a perirectal abscess.

Only four (4.3 per cent) of the patients treated with Azopyrine have subsequently required colectomy and ileostomy. In contrast to this, seven of the twenty-two cases treated before the advent of Azopyrine required surgery (31.8 per cent).

Discussion

The management of an ulcerative colitis patient should not be attempted without the use of the proctoscope as an aid in diagnosis and follow-up of the patient. It is not satisfactory to regulate medication by symptomatic improvement alone. Frequently, the mucosa will be seen to be ulcerated for several months after symptoms of the disease subside. Treatment must be continued

until there is actual healing of the mucosal lesions. Likewise, regular proctoscopic examinations will sometime reveal a flare-up of activity when the patient is not yet aware of any untoward symptoms.

Another point that must be made is that we should not be deluded into thinking that we are "curing" anyone with ulcerative colitis by means of any medicine now available. The disease is basically one of exacerbations and remissions. The best we are able to do with antibiotics, hormones, psychotherapy, et cetera, is to bring about a remission of the condition. Subsequently, the patient and physician alike should be alert for another flare-up of the process. Prompt recognition and treatment of any activity will usually bring things under control without any real disability to the patient.

It should be emphasized that while no truly specific treatment is available for chronic ulcerative colitis, medical treatment is successful in controlling the great majority of patients. There have been many times in the years that physicians have struggled with this disease when it seemed that surgery was the only hope of real improvement for victims of ulcerative colitis. Such is no longer the case. With intelligent medical management, fewer patients now develop acute fulminating symptoms and less surgery is being done. These patients must, however, be watched regularly and carefully through the years. Carcinoma of the colon is greatly increased in incidence in people with chronic ulcerative colitis. Barger¹¹ in 1954, reviewed 1,564 patients treated at the Mayo Clinic for ulcerative colitis in the years 1918-1937. A follow-up on these patients and statistical analysis of the results showed that the death rate from carcinoma of the rectum and colon among persons with chronic ulcerative colitis is thirty times greater than in the general population. The likelihood of development of carcinoma seems to increase with the duration of the disease. Dennis¹² reviewed his series and found the incidence of carcinoma as follows:

<i>Duration of Colitis</i>	<i>Incidence of Carcinoma</i>
Under 10 years.....	0 Per Cent
10-19 years	10.4 Per Cent
20 years and over.....	20.0 Per Cent

Therefore, patients who have had the disease longer than ten years should be followed regularly by proctoscopic examination and barium enema examination. Colectomy is indicated if there is

development of suspicious polypoid lesions of the mucosa or irregularities in the x-ray appearance.

After the diagnosis is established, it is our practice to institute treatment with Azopyrine. The usual dose is six to twelve tablets per day in three or four divided doses. If nausea occurs, the dosage can be reduced and later increased gradually. This schedule is continued for three weeks and then medication is stopped for one week. At that time the patient is again sigmoidoscoped. If activity persists, another course of Azopyrine is given, always resting for a week after it has been given for three weeks.

Symptomatic improvement usually occurs within the first few days of treatment. Usually two to three consecutive courses are needed to obtain healing of the mucosa. If a flare-up in activity occurs at some later date, the same plan is repeated.

Psychotherapy certainly plays a role in any successful management of an ulcerative colitis patient. For any nonpsychiatrist, this consists of understanding, reassurance, and advice.

Too much emphasis is placed by some physicians on the importance of dietary restrictions for these patients. Our advice to an ulcerative colitis patient is, "It's not what you eat, but what's eating you." No benefit is obtained from placing the patient on a soft bland diet. It is more important that he have a good general diet, high in protein and calories. The only foods that possibly should be eliminated are highly spiced food and such irritating materials as nuts and popcorn.

Cortisone and ACTH find limited application in our practice for ulcerative colitis. They have been used for a few patients who responded poorly to Azopyrine. The results are often quite satisfactory. Hormone therapy is also indicated for treating some of the complications of ulcerative colitis, including arthritis, pyoderma gangrenosum, and uveitis. In some desperately ill patients with acute fulminating colitis, ACTH and cortisone may be used to stabilize the patient. However, surgery should be done as soon as his condition permits. In our opinion, hormone therapy should not be used for the routine ulcerative colitis patient. The results with Azopyrine are just as good, and there are none of the serious complications from its use that are found with the hormones.

It is best to hospitalize a patient who is acutely

ill in an acute exacerbation. When there is fever, severe diarrhea with dehydration and electrolyte imbalance, and often serious bleeding, intensive treatment is needed. The use of broad spectrum antibiotics, intravenous fluids, and blood will often bring the situation under control.

Indications for surgery in ulcerative colitis are several, and may be briefly summarized as follows:

1. Patients with fulminating febrile attacks who are steadily losing ground despite medical therapy. Even if they respond temporarily to ACTH or cortisone, surgery should be done, as these hormones have no effect on the underlying disease process.
2. Perforation of the colon.
3. Obstruction.
4. Severe hemorrhage.
5. Patients who are semi-invalids and unable to continue in their normal occupations because of frequent severe diarrhea.
6. Debilitating infectious arthritis.
7. Colectomy should be considered in any patient having the disease over ten years, especially if there is suspicious bleeding or abnormal findings on proctoscopic or x-ray examination. The incidence of carcinoma of the colon in these patients is over 20 per cent.

Surgery should not be undertaken lightly in patients with ulcerative colitis. The operation of total colectomy does actually restore them to health as no medical treatment can, but there are several other factors to be considered. Most patients learn to live with and care for an ileostomy quite well and are well adjusted. Nevertheless, quite an emotional adjustment is necessary, and unless there are good indications for surgery, it is best left undone. Furthermore, surgery on an ulcerative colitis patient seems to be fraught with more complications than most other operations. Cooper¹³ in 1956 reported the complications that followed surgery on 107 patients with ulcerative colitis. Only 23 per cent of these patients failed to develop a postoperative complication. Colcock¹⁴ recently reported a series in which the incidence of complications was very similar.

Intelligent use of all methods at our command, medical and surgical, is yielding better results in the treatment of ulcerative colitis than have ever been possible before. Let us hope that the search for a specific treatment for the disease is a short one.

Summary

1. A review of the evolution of medical and surgical treatment of ulcerative colitis has been presented.

2. The results of treatment of 114 cases of ulcerative colitis are described.

3. Azopyrine is the drug of choice for ulcerative colitis. Limited use of ACTH and cortisone and psychotherapy are helpful.

4. It is important that proctoscopic examination be utilized for diagnosis and follow-up of the patient.

5. It is possible to induce a remission of the disease, not a permanent cure, by medical treatment.

6. The operation of choice for ulcerative colitis is removal of the entire colon and rectum with construction of an ileostomy. This is all done in one stage if possible.

7. It is possible in the great majority of cases to manage patients with ulcerative colitis by medical means. Surgery is reserved for complicated and intractable cases.

(Continued from Page 546)

nervous and a behavior problem, while the fourth patient seems clinically well.

This brings the total pertussis vaccine cases to nine, six with severe neurologic involvement and two with moderate involvement. Only two are considered completely well. Three of five children with pertussis infection are considered to be essentially normal.

Renal Failure following the Administration of Intraperitoneal Neomycin

LLOYD D. MAC LEAN, M.D., Ph.D.
Saint Paul, Minnesota

MANY clinical and experimental reports exist in the literature on the benefits of intraperitoneal neomycin in the treatment of acute bacterial peritonitis, or for prophylactic purposes following routine abdominal surgery.¹⁻⁶ In a comparative investigation neomycin was considered the drug of choice among oxytetracycline, tetracycline hydrochloride and neomycin.¹ One recommended regimen is as follows: One gram of neomycin in 500 ml. of normal saline at the time of surgery and 0.5 grams of neomycin in 250 ml. of normal saline every six hours thereafter, via polyethylene catheters placed into the peritoneal cavity at the time of surgery. The postoperative treatment is maintained for as long as seventy-two hours with a total dose of as much as 7 grams of neomycin. This regimen is very effective in sterilizing the peritoneal cavity.¹ While it is known that neomycin is a nephrotoxic drug, clinical trial and experimental evidence would appear to have established the safety of the above regimen.^{1,2}

Following is a case report of death from renal failure occurring after the instillation of neomycin for peritonitis associated with appendicitis with rupture.

Case History

Mr. A. J., aged fifty-five, was hospitalized eighteen hours following the onset of lower abdominal pain which had localized in the right lower quadrant. Six hours prior to admission the patient experienced excruciating lower abdominal pain with radiation to the back. There was some relief following this episode. He vomited bile-colored material on four occasions before hospitalization. The patient had a normal bowel movement on the day of admission. He preferred to lie on his side with knees flexed on the abdomen and he avoided all unnecessary movement. His pulse rate was 112, and regular and blood pressure 140/80. Examination of the abdomen revealed widespread board-like rigidity, tenderness and rebound tenderness. Bowel sounds were absent and rectal tenderness existed in all quadrants.

Roentgen examination of the abdomen revealed small

and large bowel distention and a laminated radio-opaque stone in the region of the appendix, believed to represent a fecolith. Laboratory examination revealed a leucocyte count of 12,500 with 80 per cent neutrophils, 18 per cent lymphocytes and 2 per cent monocytes. The hemoglobin was 15.8 gms., serum amylase within normal limits. Urinalysis was negative, with a specific gravity of 1.029 (before intravenous glucose). The blood urea nitrogen was 19 mg. per cent, CO₂ was 30 meq/l and Cl 100 meq/l.

Emergency laparotomy was performed two hours following admission and a foul, watery exudate poured from the abdominal cavity. A gangrenous, perforated appendix with a fecolith at the base was removed. A severe, generalized peritonitis existed with accumulations of pus of 300 ml. in the pelvis and 200 ml. in both subphrenic spaces. Cultures of this material grew *E. coli*. All purulent material was aspirated and the peritoneal cavity was lavaged with saline. Polyethylene catheters were placed in both subphrenic spaces and in the right lower quadrant to be used to instill neomycin solution during the postoperative period. One hundred ml. of 1 per cent neomycin was placed in the abdominal cavity prior to closure. One unit of blood was given following surgery.

The patient was not hypotensive during or following surgery nor did he exhibit chills. The rectal temperature never exceeded 101.8° F. Over the first thirty-six hours following operation the patient received 3 grams of neomycin intraperitoneally as a 1 per cent solution. Parenteral penicillin and streptomycin were also given.

The patient responded to the treatment with return of temperature to normal and return of bowel activity by the fourth postoperative day. An adequate urine output existed throughout the illness (Table I). During this period the urine excreted revealed a fixed specific gravity (1.010) and uremia rapidly developed. The patient became progressively more lethargic and confused, and expired with bronchopneumonia on the sixteenth postoperative day. Table I contains pertinent fluid, electrolyte and serum chemistry data during the hospital course.

Postmortem examination* revealed bilateral bronchopneumonia (*Pseudomonas aeruginosa*). The kidneys showed swelling of the proximal tubular epithelium and hydropic degeneration. The tubular epithelium showed extensive degeneration with some regeneration. The

microscopic appearance was compatible with a toxic nephropathy but not consistent with a transfusion reaction. Only minimal peritonitis remained at the time of death.

Discussion

Neomycin does not produce a pathognomonic alteration in the gross or microscopic appearance of the kidney, and for this reason one cannot state categorically that the renal failure encountered in the patient under consideration was produced by neomycin. However, it is strongly suggested that neomycin was the causative factor, since the patient had normal renal function preoperatively, underwent a relatively simple operation without occurrence of hypotension, oliguria or clinical evidence of bacteremia, but developed progressive renal failure starting within twenty-four hours of the time intraperitoneal neomycin was instilled. The pathologic examination did reveal a severe toxic destruction of the kidney compatible with a drug reaction and not characteristic of an incompatible blood transfusion.

The amount of neomycin utilized in the treatment of this patient was less than one-half that considered safe on the basis of experimental and clinical observation.^{1,2} Experimental evidence on the safety of intraperitoneal neomycin is based on studies in normal animals.⁷⁻⁹ It is definitely possible that peritonitis with increased vascularity of the peritoneal surfaces could greatly increase the absorption rate from the peritoneal cavity.

Neomycin is commonly used as a topical, prophylactic antibiotic during or following routine abdominal surgery. Although the quantities instilled at this time are usually not greater than two grams, the safety of this practice is also questioned, especially since respiratory arrest has also been de-

scribed following the administration of intraperitoneal neomycin.³

It is felt that intraperitoneal neomycin may have contributed to other instances of postoperative renal failure not as easily discernible as in the patient presented.

Summary

A case report exhibiting renal failure following the use of intraperitoneal neomycin in the treatment of acute bacterial peritonitis is presented. Based on a critical evaluation of the patient presented and a review of the literature, it is suggested that the dose of neomycin which can be safely placed in the peritoneal cavity, has not yet been determined.

Surgical Approach to Esophagitis with Hiatus Hernia

S. W. HUNTER, M.D.
RALPH OLSON, M.D.
Saint Paul, Minnesota

AT A gathering of a dozen surgeons, there are invariably twelve methods of treating the problem of peptic esophagitis compounded with hiatus hernia. In his address to the Arkansas Academy of Medicine in 1955, Dr. Alfred Kahn¹ concluded his thesis by stating, "The perfect surgical therapeusis for this condition is yet to be devised!" In the large majority of cases involving both conditions, patients are cured simply by repairing the hernia. This presentation concerns those with more severe esophagitis. For the moment let us consider the esophageal element.

Literary Background

In 1786, Sir John Hunter recognized and described esophagitis and ulcer of the esophagus. Schridde,² a German pathologist, in 1904 found heterotopic gastric glands in the esophagus in 66 per cent of postmortem examinations, one as high as the cricoid cartilage. Taylor³ found gastric mucosa in only six cases out of 900 examinations.

Most authors now agree that regurgitant gastric juice is the main etiologic agent.

Arroyave, Clatworthy and Wangenstein⁴ implanted 1.5 sq. cm. gastric mucosa in the esophagus of dogs with the nerve and blood supply intact. All dogs showed esophageal ulcerations, some as early as thirty days.

Ripley, Leary, Grindlay, and Seybold⁵ showed the same results by anastomosing the fundus of the stomach to the distal esophagus through a prepared defect in the diaphragm. Their experimental operation was somewhat similar to the Grondahl operation for cardiospasm. They also found esophagitis following esophago-gastrostomy. Colonel Palmer⁶ at Walter Reed Hospital, on the other hand, is adamant that the acid peptic factor is not the primary inciting factor in esophagitis, and maintains that the mucosa is not damaged primarily, but is secondary to an injured lamina propria. He offers no surgical correction.⁶

Wangenstein and Leven⁷ have held that three-

fourths resection of the stomach is an effective method of treatment. They favor bougienage pre-operatively and postoperatively if necessary. Ripley

Fig. 1. Schematic drawings of the three esophagoplastic operations. The Grondahl and Wendel procedures involve complete wall incision with subsequent repair to enlarge esophagogastric junction. The Heller procedure is an incision down to the submucosa.

and his group⁵ do not agree that three-fourths resection protects the experimental animals from esophagitis. Sweet favors resection of the upper part of the stomach with esophagoantrostomy. Wangenstein, Clatworthy, and Arroyave² in their studies found that neither the sleeve resection nor the Bilioth II protected against esophagitis in the esophageal gastric implant animals.

In regard to the use of vagotomy in this dilemma, Geever and Merindino⁸ concluded after a short series of dogs that vagotomy combined with the Heller or Grondahl procedure was an unfortunate combination; if anything, it aggravated the esophagitis. However, they did not do any type of "drainage" operation; they assumed it would not work on the basis of previous work. Brackney, Wangenstein et al,⁹ on the other hand, found that a Heller or Wendel operation with vagotomy and pyloroplasty did not result in histamine induced esophagitis (Fig. 1).

The hiatus hernia repair has been bypassed thus far, as it seems to be the lesser of the two evils. The majority of surgeons seem to favor the

Presented at a meeting of the Minnesota Surgical Society, Saint Paul, October, 1956.

thoracic approach, but a few feel the abdominal method is preferable (Fig. 2). The most recent addition to these techniques is one offered by Nissen¹⁰ of Switzerland, which does not interfere

Fig. 2. Esophageal hiatus shown with crura of the diaphragm forming the margin. The muscle can be approximated quickly to effect an adequate repair of the hernia.

with the hernial sac. He simply pulls the stomach into the peritoneal cavity and attaches it with rectus fascia strips to the anterior rectus fascia. He then stitches the anterior stomach wall to the parietal peritoneum at the incision. He calls the operation a gastropexy. He has operated on five patients, all of whom were of advanced age.

The question is, where do we go from here? When the internist has exhausted his dietary and drug therapy, when the patient still has crippling heartburn, when hernia is present, and when stricture or ulcer are evident we must offer some surgical therapy. Recently, we have treated two such patients with hernia repair from below, bilateral vagotomy and pyloroplasty (Fig. 3). The details of the operation need no laboring. A mid-line umbilicus to xiphoid incision is used. The xiphoid may be removed for added exposure, and

a minimal split of the sternum may be necessary in obese individuals. The triangular ligament of the liver is cut, and the left lobe of the liver retracted medially. The esophagus is easily dis-

Fig. 3. Schematic representation of the three phases of the operation: (a) crura brought together to repair the hernia; (b) vagi cut bilaterally; (c) Heineke Mikulicz pylorotomy.

sected from its peritoneal attachments and displaced anteriorly with a Penrose sling. The vagus nerves at this point are cut, and all of the ramifications are stripped from the esophagus to be sure of cutting each and every fiber. The hernial sac is removed and the crura closed behind the esophagus with 2-0 silk, taking generous bites with each stitch. The esophagophrenic ligament is then reconstituted with a few 4-0 silk stitches from the outer wall of the esophagus to the peritoneum and the underlying ligament, and finally the Heineke-Mikulicz pylorotomy is carried out with the usual 3 to 4 inch longitudinal incision with transverse closure. It is not possible in the space allotted to describe the different types of esophageal hernia nor to touch on the concepts of Allison regarding the esophagophrenic ligament.

Case Reports

The first case is that of a married man, aged thirty-seven, who consulted his doctor for severe "heartburn" of five years' duration. He had regurgitation, inability to eat solid foods, and a gradual aggravation of symptoms to the point of difficulty with liquid foods (Fig. 4). He tried every conceivable antacid, antispasmodic and tranquilizer, but his situation was deteriorating. The gastric analyses with histamine are shown in Table I.

He also had occult blood in the stool on two examina-

tions. The preoperative diagnosis was esophagitis with hernia. Following surgery, he presented no problem aside from transient diarrhea controlled easily with paregoric. He now has no trouble with diet and considers himself completely cured. He is back to full-

as the first patient in July, 1956.

She was as gratifying as the first patient, but after discharge developed a mild anxiety with loss of appetite and regurgitation. Repeat barium swallow showed a defect in the esophagus just at the operative area (Fig.

Fig. 4. Preoperative esophagogram (*two upper views*) show upper third of stomach herniated into chest, accompanied by esophageal stenosis. Post-operative esophagogram (*two lower views*) shows reduced hernia with adequate esophageal lumen.

time work and recently drank eight bottles of beer at a bowling party without adverse effect.

The second case is that of a married woman, aged forty-seven, who had an identical story, with radiation of the subzyphoid pain to the back and shoulders (Fig. 5, *above*). Her gastric analyses with histamine are shown in Table II. This patient had the same operation

5, *lower left*). Esophagoscopy was done and an ulcer could not be confirmed, nor was esophagitis found. It is possible the defect was produced by one of the stitches from the esophagus to the peritoneum. The patient responded to a bland diet with an antacid and the deformity seems to be less prominent in subsequent x-rays (Fig. 5, *lower right*).

TABLE I. GASTRIC ANALYSES (E.R.)

Time	Preoperative	Postoperative
Fasting	0	6
15' after histamine	14	24
30' after histamine	56	20
45' after histamine	45	3
60' after histamine	107	0
75' after histamine		0

TABLE II. GASTRIC ANALYSES (E.F.)

Time	Preoperative	Postoperative
Free		0
20' after histamine	55	0
40' after histamine	86	20
60' after histamine	81	25

Fig. 5. Two views (*above*) of the hiatus hernia also demonstrate narrowing of the esophagus just above the esophagogastric junction. Picture on the right shows cardia filled with gas. (*Lower left*) Small fleck of barium can be seen just above the diaphragm—thought to be small ulceration. Subsequent esophagram revealed this defect to be gone. (*Lower right*) Original ulceration area is now clear, and there is adequate esophagogastric junction.

Perhaps repair of the hernia repair alone would have sufficed in these two cases. In the great majority of instances, this is certainly the case, but in view of the pronounced esophagitis, it seems unlikely. Since “drainage” operation prevents the puddling of gastric content, since the acid content has been markedly decreased, since a pitchcock mechanism has been restored, and since the extra procedure adds very little time to the procedure, it seems that this operation has some merit.

Treatment of Congestive Heart Failure

MILTON W. ANDERSON, M.D.
Rochester, Minnesota

ONLY a few years ago, recognition that a patient was having congestive heart failure meant that diagnostic efforts with respect to his problem could come to an end. With few exceptions, the specific cause of heart failure was unimportant from the standpoint of treatment, since essentially the same routine measures applied to each patient. The fund of information regarding heart failure and its treatment fortunately has increased so that management of the problem now must be much more exacting and intimately involved with diagnostic studies. The physician of today no longer is permitted the luxury of calling congestive heart failure a diagnosis but must accept it as a symptom complex and as a challenge to his diagnostic acumen. To a large degree, the clinician owes to the cardiac physiologist and the cardiac surgeon the responsibility for establishing an exact anatomic and functional diagnosis in all cases of congestive heart failure. The joint efforts of these specialists have led to the alleviation and cure of many types of heart disease that hitherto could only be palliated. In view of this added responsibility, the application of special diagnostic tools or the obtaining of special consultation becomes a necessity for certain patients in whom the anatomic diagnosis is not readily apparent.

Cardiac Diseases of Surgical Interest

Examination of the patient with the possibility in mind that surgical treatment may be effective is now a necessity in an increasing number of types of heart disease (Table I). The list of surgically correctible congenital malformations has grown greatly in the past year or so with the availability of an adequate mechanical bypass for the extracorporeal support of the patient's circulation during operation. In rheumatic heart disease, the benefit of surgical relief of mitral stenosis is generally known; in addition, selected patients who

have aortic valvular disease, both stenosis and insufficiency, are being helped by a surgical approach, and surgical methods for mitral insufficiency are being developed that show promise

TABLE I. TYPES OF HEART DISEASE

of correcting that valvular defect. Tricuspid stenosis, a relatively uncommon lesion, can be approached surgically on the right side of the heart in a fashion similar to the operation for mitral stenosis on the left. Constrictive pericarditis is a surgically amenable lesion to be considered as a possible diagnosis in any patient who has the findings of failure of the right side of the heart, especially if ascites is present. In a few instances, it has been possible to diagnose atrial tumors by means of angiocardiography; these lesions should lend themselves to surgical removal, utilizing new methods of operative approach.

Operative intervention is indicated for systemic arteriovenous fistulas that are putting strain on the heart. An uncommon cause of hypertensive heart failure is the pheochromocytoma, a functioning tumor of the adrenal medulla. This possibility especially should be considered in persons who have intermittent hypertension or those with sustained hypertension who exhibit excessive sweating, tachycardia, glycosuria or other unusual features. The physician should be prepared to

Acute rheumatic carditis

conduct tests to confirm or eliminate the diagnosis. Positive results of such tests, especially if reproducible, are evidence for surgical exploration of the adrenal gland. Similarly, a few cases of hypertension secondary to aldosteronism caused by a functioning adrenal cortical tumor have been reported.¹ Since this syndrome is associated with decreased serum potassium, values for this ion should be determined in hypertensive patients who have polyuria or periodic weakness.

Cardiac Diseases Amenable to Special Medical Measures

The internist or general practitioner also encounters patients who have certain diseases that produce heart failure in whom he can, by proper treatment and advice, greatly reduce the burden of extra activity of the heart (Table II). Essential hypertension causing congestive heart failure now can be controlled to the benefit of the patient by use of a variety of effective drugs, including the Rauwolfia preparations, hydralazine and the ganglion-blocking agents. The plan of attack with these drugs must be individualized depending on the severity of the hypertension and its response.

Heart failure associated with hyperthyroidism lends itself to specific therapy, which consists mainly today of the eradication of the hyperthyroidal state by use of radioactive iodine. If such treatment is not available, use of the antithyroid drugs may be substituted. Although some controversy exists concerning whether heart failure ever is caused by myxedema alone, it can occur in the presence of hypothyroidal states and the judicious use of desiccated thyroid will alleviate the symptoms. Heart disease caused by beriberi is almost unknown in this part of the country. It can, of course, be treated specifically by use of thiamine.

Bacterial endocarditis may precipitate heart failure in an otherwise compensated heart with valvular deformity, and it requires specific antibiotic therapy based on the causative organism and its sensitivity to various drugs. When congestive heart failure occurs in a child or young adult as a con-

sequence of acute rheumatic carditis, the toxicity as manifested by fever, pain and tachycardia can be alleviated by the use of cortisone and related substances.

The beneficial effects that can be accomplished in selected types of heart disease re-emphasize the value of specific diagnosis to allow the application of specific therapy.

Nonspecific Measures

Nonspecific therapy is also available for patients who have congestive heart failure, both those for whom specific treatment is not known at present and those in whom it is desired to bring about compensation in conjunction with specific treatment. Since the presence of congestive heart failure implies that cardiac reserve is lost and that the heart no longer is able to maintain an effective output, certain general considerations may be applied for the purpose of reducing cardiac work irrespective of drug therapy (Table III). First, the patient must know that he no longer can pursue full and vigorous activity but must secure increased rest and follow a life of moderation. These measures should be carefully outlined by the physician as based on firsthand knowledge of the patient's work and habits. A dietary schedule for the removal of excessive weight is a necessity for the obese patient as a means of reducing cardiac work. Anemia causes a compensatory increase in cardiac output, with resultant overwork; the anemia should be corrected medically or surgically, with replacement of blood if necessary. Similarly, a patient with decreased cardiac reserve frequently is plunged into failure as a consequence of infection, respiratory or otherwise, which accentuates cardiac work. This extra burden on the heart should be removed by the use of suitable antibiotics or chemotherapy, or other indicated measures.

The judicious administration of sedative drugs is of importance both to allay anxiety and reduce overactivity on the part of the patient with heart failure. It is of benefit in his program of rest. The choice of medication and the dose are individual-

zed, depending on the patient as well as the prescribing physician. Narcotics should be avoided when the condition is chronic. Finally, as a non-specific measure, consideration occasionally should be given to the production of a hypometabolic state, as emphasized by Blumgart and Freedberg.² The production of hypothyroidism by means of radioactive iodine has its indication for the patient whose chronic congestive heart failure cannot be controlled otherwise despite careful medical management.

Treatment of Acute Pulmonary Edema

Acute pulmonary edema, a manifestation of severe left ventricular failure, is a true medical emergency that may occur as the first evidence of heart disease or, in the patient being treated for chronic congestive failure, as a result of any factor causing sudden increase in cardiac work. Although many hiatuses are present in the knowledge of the mechanism of acute pulmonary edema, the management of this state is fairly well established (Table IV).

Morphine sulfate traditionally is considered as a specific in the emergency care of the patient with acute pulmonary edema. It should be used in all such cases unless there is specific contraindication, such as known intolerance to the drug, or unless the pulmonary edema is related to cerebral disease or chronic pulmonary disease. It may be administered subcutaneously in doses of one-sixth or one-fourth grain; if urgency is indicated, similar doses should be given slowly intravenously. It is probably wise to give atropine sulfate at the same time. Morphine has the effect of alleviating anxiety and disrupting harmful reflexes that overstimulate the respiratory mechanisms. The need of oxygen is indicated by the dyspnea and cyanosis. Oxygen should be given preferably by means of a face mask to insure high concentration. If a mask is not tolerated, use of a tent or nasal catheter may be necessary. Clinical data show that the act of breathing against a pressure of 3 to 6 cm. of water benefits the patient by decreasing the transudation of fluid into the lungs.

When evidence exists of increased venous pressure and venous return to the heart, the interruption or slowing of venous return by the application of tourniquets to the extremities or by phlebotomy and removal of 500 ml. of blood is beneficial. When tourniquets are used, they should be applied to the proximal part of the extremity at or slightly less than diastolic pressure in order to permit entrance of arterial blood into the extremity but to inhibit venous return. Tourniquets should be applied to only three extremities at a time and should be rotated every fifteen minutes.

Rapid digitalization by the intravenous route has its greatest function in the management of acute pulmonary edema. Although in the past, the rapidly acting cardiotonic drugs, including ouabain and other preparations of *Strophanthus*, enjoyed wide use, lanatoside C and other glycosides of *Digitalis lanata* (Digoxin) appear to be the drugs of choice at present. If the patient has not received digitalis recently, 1.0 mg. of either of the two last-mentioned drugs may be given slowly intravenously as an initial dose; an additional dose of 0.5 or 0.6 mg. after two to four hours may be infused if it is needed. For the patient who has received digitalis previously and is believed to be near digitalization, doses of 0.2 to 0.4 mg. of lanatoside C can be given initially and repeated in two to four hours unless evidence of toxicity from digitalis occurs. After recovery from pulmonary edema, the patient should receive one of the longer-acting oral preparations of digitalis. When acute pulmonary edema results from a severe hypertensive crisis, it may be lifesaving to reduce blood pressure rapidly by the careful parenteral administration of a potent antihypertensive drug. The alkaloids of *Veratrum*, as well as hydralazine and hexamethonium, have been used intravenously, and reserpine is effective by intramuscular injection. Use of these agents requires that the patient be hospitalized under constant supervision and that the cautions, contraindications and directions which accompany these drugs be carefully adhered to.

Aminophylline given intravenously has a place in the management of pulmonary edema unless hypotension or shock is present, in which case it should not be used. Its beneficial effect apparently results from bronchial dilatation. The slow intravenous drip method, in which 0.5 gm. of the drug is given in 100 ml. of a 5 per cent solution of dextrose, is safe and effective.

The use of ethyl alcohol vapor and the aerosolization of solutions of silicone have been introduced recently in the management of acute pulmonary edema for their antifoaming effect.³ These agents cause reduction of the frothy sputum by their effect on surface tension. They are administered by allowing oxygen to bubble through the agent between the oxygen tank and the mask or tent.

Management of Chronic Congestive Heart Failure

Chronic congestive heart failure typically is manifested by pulmonary congestion, edema of the legs and abdominal wall, and the presence of free fluid in the serous cavities. The patient is best hospitalized to permit the accomplishment of several goals (Table V). First, the specific cause can be determined more easily in the hospital than at home; secondly, hospitalization insures adequate rest; thirdly, maximal therapeutic efforts are more easily accomplished in a hospital; finally, by pursuing a cardiac regimen in the hospital, the patient learns the details of diet and other important factors that will help him maintain cardiac compensation in the future.

Since Withering reported the experience of the old lady from Shropshire, there has been no more specific therapy for the failing heart than digitalis in one form or another. Rapid intravenous digitalization usually is not necessary in chronic congestive heart failure. The relative advantages and disadvantages of the various preparations of digitalis in common usage today, which include digitalis leaf, digitoxin, Digoxin, gitalin and, to a lesser degree, several others, will not be discussed here. Basically, all such preparations have similar cardiotonic properties, and it is most important that the physician familiarize himself thoroughly with one or two preparations and utilize them rather than attempt to use all those available. A patient who is well controlled on a certain drug should not be subjected to change of medication at the whim of the physician. The dosage of the various preparations is widely publicized and needs only the comment that individualization is necessary; unhappily, the method of trial and error is still needed to insure an adequate effect from digitalis without toxicity. The physician further is obligated to impress on his patient the fact that digitalis cannot be used haphazardly and have an optimal effect. Unnecessary expense and disability occur far too frequently because the physician fails to advise the patient that digitalis will be necessary

TABLE V. MANAGEMENT OF CHRONIC CONGESTIVE HEART FAILURE

Hospitalization
Digitalization
Restriction of sodium
Diuresis
Mechanical removal of fluid
Administration of anticoagulants

for him always and that he must continue to refill his prescriptions.

To relieve the patient of the accumulated fluid restriction of sodium occupies a key role. For the patient with severe heart failure who accumulates fluid readily, a diet permitting only 0.5 gm. of sodium per day should be carefully outlined, preferably by a hospital dietitian or with the aid of printed material. When the failure is mild and easily controlled, a diet containing 2 gm. of sodium can be permitted. Again, the patient must be impressed with the necessity of continuous observance of dietotherapy.

A large number of diuretic agents are available for the management of dropsy. The use of diuretics only after severe symptoms of retention of fluid have developed is wrong. Instead, a program should be set up whereby use of such agents keeps the patient free of excessive fluid and comfortable, rather than in a constant state of being partly waterlogged. This is done best by initially hospitalizing the patient to obtain maximal benefit from diuretic therapy and instructing him to be alert for reaccumulation of fluid by weighing himself to detect such retention before it reaches the point of producing pulmonary congestion or overt edema.

The most effective diuretic for congestive heart failure uncomplicated by renal insufficiency is one of the organic mercurial agents administered parenterally. Mercaptomerin (Thiomerin), which may be used subcutaneously, or mersalyl (Salurgan)-theophylline or meralluride (Mercurhydrin) given intramuscularly or intravenously can be given daily or every other day in doses of 1 or 2 ml. during the patient's hospitalization until the "dry weight" is obtained. In the case of stubborn retention of water, ammonium chloride can be used in daily divided total doses of 6 to 12 gm. to potentiate the effectiveness of the mercurial. When cardiac compensation has been obtained and the patient is free of excessive fluid, the maintenance of this state will require a wide variation of diuretic therapy. When the disease is mild, restriction of sodium and the use of digitalis usually prevent

accumulation of fluid. In other cases, the intermittent utilization of orally administered diuretics, such as acetazolamide (Diamox), chlormerodrin (Neohydrin), mercumatilin (Cumertilin) or ammetradine (Mictine) in doses found by clinical trial to be tolerated and effective will prove satisfactory. In the more severe degrees of chronic congestive heart failure, the regular use of mercurials by the parenteral route two or three times weekly, together with the regular administration of ammonium chloride, will be necessary. The modern diuretic management of congestive failure implies the outlining of a program that will keep the patient clinically in cardiac compensation by means of the most conservative treatment from the standpoint of discomfort and expense to the patient; such a program, of course, demands careful individualization. The xanthine drugs, particularly aminophylline, can be used alone as mild diuretic agents, particularly in the form of rectal suppositories, or they can be used also to accentuate the effect of the mercurial when they are given intravenously.

Two complications that may appear during use of mercurial diuretics for severe resistant chronic congestive heart failure have been publicized recently and are worthy of brief comment. They are intractable heart failure complicated by the so-called low-salt syndrome and the development of cardiac arrhythmia. In the former, low values for serum sodium and chloride are found, together with azotemia and retention of fluid. Whereas attempts at improving the patient's condition by replacing sodium chloride rarely have been effective, Rubin and associates⁴ recently demonstrated that restoration of the responsiveness to mercurials can be accomplished by using ammonium chloride and Diamox over a period of several days to produce hyperchloremic acidosis. When this electrolytic state was produced, the diuretic response to mercurials was restored and the patient improved.

Cardiac arrhythmia in the digitalized patient during mercurial diuresis is a manifestation of digitalis toxicity secondary to depletion of potassium. Brown and Levine⁵ demonstrated the occurrence of paroxysmal auricular tachycardia with block as a specific arrhythmia in this syndrome. This arrhythmia can be interrupted and the former rhythmic mechanism restored by giving potassium chloride by mouth in 2-gm. doses every two to four hours or four to six doses or by the intravenous administration of 40 mEq. of potassium chloride diluted in

1 liter of a 5 per cent solution of dextrose.

Mention should be made of the mechanical removal of fluid. Massive pleural effusion and ascites are frequently resistant to mobilization, particularly in cases of intractable disease in which intensive diuretic therapy aggravates electrolytic imbalance. In such instances, thoracentesis and abdominal paracentesis can give immense relief to the waterlogged patient. Infrequently, drainage of fluid from dependent parts of the body by means of Southey's tubes or use of hypodermic needles has a place, particularly for persons sensitive or resistant to mercurial diuresis.

Anticoagulant therapy has a role in the management of selected patients with congestive heart failure. This treatment should be instituted in the presence of thrombo-embolic phenomena and in cases of intractable disease in which the presence of repeated small pulmonary emboli is suspected. The frequency with which pulmonary and peripheral thrombosis and embolization occur during active therapy for congestive failure might justify the use of anticoagulants as a more or less routine measure during hospitalization, especially when extensive anasarca or auricular fibrillation is present. Unfortunately, the association of complicating renal and hepatic dysfunction often contraindicates such prophylaxis.

Summary

The modern management of congestive heart failure demands that definitive anatomic and physiologic appraisal of the etiologic basis of the cardiac lesion be accomplished. This responsibility is necessary for the adequate selection and treatment with surgical or specialized medical measures of those patients whose cardiac disease lends itself to specific therapy.

In the nonspecific medical management of patients with congestive heart failure, individualization, although time-consuming, is essential in determining the dietary, cardiotonic and diuretic treatment for each patient. That program, as eventually established, is one which should be neither too confining nor too liberal for adequate control of the patient's individual needs.

The Masonic Memorial Hospital and the Cancer Problem

OWEN H. WANGENSTEEN, M.D.
Minneapolis, Minnesota

THE CONTINUED meeting of the Masonic Orders upon the campus of the University of Minnesota is symbolic, I am certain, of the spirit of mutual helpfulness which permeates the roots and fabric of our respective organizations. In the final analysis, the actions of nations and organizations express merely the sentiment of a few individuals, who because of qualities of leadership, speak for the groups. The Samaritan quality of man helping man is a celestial attitude. Our meeting here already, I feel, has set in motion a continuing process which will cement a strong bond of trust and mutual sympathy which will redound to the mutual advantage of both organizations, multiplying the fruits of our joint labors in making this a better community in which to live. The University takes great pride in its association with the Masonic Orders, which have come forward to lay an important gift upon the altar of this community—a hospital to provide a home and suitable medical care for patients in the advanced stages of cancer.

In any enterprise, there are two strong allies which afford great help and strength in any undertaking: I speak of cause and need. Cancer is a great cause, and there is important need for the hospital which representatives of the Masonic Orders have proposed to provide. In fact, there is a crying need for this type of institution throughout the breadth and length of this great land. As Dean Diehl said, other areas in Minnesota would do well to provide this type of facility for the care of patients with advanced cancer. Present provisions to meet this need in the state of Minnesota are grossly inadequate.

Another great voluntary organization in this state, the Veterans of Foreign Wars, is proposing to build also on the campus of the Medical School a Clinical Research Facility for the express purpose of fostering studies on patients with cancer. This

additional small research unit to be placed in immediate juxtaposition to the Masonic Memorial Hospital, it is hoped, may provide window through which sunlight and hope will come; fruits of research to bring aid to the flagging spirit of many a patient afflicted with cancer. In the life of every family, there are periodic stormy currents, occasioned by illness, which wreck havoc upon plans and contemplations of the pleasantness of life. Such a foe is cancer. It may come at an age of life; however, increasing years is its commonest denominator.

The word fanaticism crept into our language during the religious persecutions of the seventeenth century. If a fanatic can be described as one who continually harps on a subject and never changes his mind about it, I fear that the facility with which the subject of cancer and its problems come to my lips brings me within the range of that definition.

In 1954, more than 230,000 persons died of cancer in this country. In 1957, that figure was approximately 270,000. One of the great benefactions of medicine to mankind has been longer life, and as more people live to be old, the toll from cancer will be greater. Today deaths from cancer in the United States each year approximate half the population of the city of Minneapolis. Of Minneapolis residents, nearly one thousand will die of cancer in 1957—about three times as many people as are gathered here today, in the interest of providing added protection against this dreadful scourge.

When will all this carnage stop? When will the mortality from cancer follow the pattern of improvement which has characterized the decline in mortality from infectious diseases? At the turn of the century, tuberculosis and other prevalent infectious diseases took the largest toll of lives. Today, those ailments no longer hold the serious threat which they once posed. Today, heart disease, cancer and accidents are responsible for approximately 80 per cent of all deaths. Cancer alone accounts for somewhat less than 20 per cent

From the Department of Surgery, University of Minnesota.

Remarks made at "Hit the Million Mark" Luncheon of the Masonic Orders held at the Coffman Memorial Union, April 13, 1957.

all deaths. In other words, somewhere between one in five or six persons will die of cancer.

Today, we are curing approximately one-third of all patients found to have cancer. One of the startling developments in the cancer field has been the decline in deaths from cancer of the cervix and the uterus. Over the period of the last ten years, the Metropolitan Life Insurance Company records a 30 per cent decline in deaths among its workers from uterine cancer—confirmation of the well-known fact that early diagnosis leads to improved results. Even in so devastating a malignancy as cancer of the stomach, our experience at the University Hospitals indicates that of patients who come with localized cancer of the stomach, which has not spread to lymph nodes, 70 per cent can be cured by operation. The truth of the matter, however, is that, the ultimate cure rate of cancers of the stomach seen in our clinic is only a little better than 12 per cent. It is the long, silent interval which we need to fear in cancer. That is one of the reasons that the work sponsored in our University Cancer Detection Center, by the Minnesota State Medical Society, and the Minnesota Division of the American Cancer Society has proved so fruitful. Of asymptomatic patients coming there, one in thirty-six has been found to have a cancer. And of those having such asymptomatic cancers, the cure rate is high, for as we have learned to know, the length of the silent interval, when patients have no symptoms from cancer, is in the area of twenty months.

If the Minnesota State Medical Society and the Minnesota Division of the American Cancer Society were to sponsor jointly a program under which every person past forty-five years of age were to report to his physician for an annual check-up, submitting to examinations prescribed by joint committees of those two groups, I believe that our mortality record from cancer in Minnesota would improve. Certainly, an annual proctoscopic examination could succeed in recognizing the precursors of cancers of the rectum and the lower reaches of the colon when something more definitive could be done to bring about more frequent cures of such cancers than is our experience now. In fact, an experience like that reported by the Metropolitan Life Insurance Company for cancer of the uterus could then very well happen with cancers of the rectum and lower colon, too. Today in the United States the mortality from cancer of the rectum and colon together exceeds deaths

from cancer of any other organ. The reason: cancer of the colon and rectum is frequent in both men and women. Why not an annual birthday check-up for every Minnesotan past forty-five years of age?

Among nations and individuals, victories are not won by vanquishing our enemies, but by understanding them. In a disease, on the contrary, we may learn to overcome it before we understand it. I need only mention the experience of smallpox. Other instances could be cited. In cancer, we already know that finding the early case is the most important facet of the problem. The tubercle bacillus has been known for more than seventy-five years. Yet it took two decades of experience to appreciate the importance of that discovery to the extent that this knowledge could be utilized to the end that tuberculosis as a disease became less frequent. Today less than 3 per cent of deaths are occasioned by tuberculosis—in fact, the threat of tuberculosis as a serious disease has been won.

We already know that the important thing in cancer today is to get at the early case. In a number of cancers—lip, stomach, colon, rectum and breast—if the lymph nodes are not involved when the cancer is removed, the cure rate is high—in the area of 75 per cent. Until screening tests are available to inform us what kinds of things to look for as symptomatic of the presence of silent cancer, until then, we must continue to push cancer detection on a broad front throughout our country. Already, some progress has been made in cancer detection. I need cite only the work of Dr. George Moore of the Roswell Park Cancer Hospital in Buffalo here some years ago with fluorescein. It was when Dr. Moore was here as a surgical interne at our University Hospitals, almost ten years ago now, that he observed the great affinity of brain tumors for fluorescein. That was the first important objective screening test devised for the recognition of cancer. Professor Komei Nakayama of Chiba City, Japan, observed that many cancers had greater attraction for radioactive phosphorus than did normal tissues. Nakayama devised small Geiger counting tubes which he mounted on long, narrow, flexible tubes to be inserted into the esophagus and stomach to help aid the detection of cancers of these organs. My own associates, Drs. Donald B. Shahon and Joseph B. Aust, have confirmed Professor Nakayama's findings, and continue to explore means of detecting

cancers in these areas earlier than we now do. Drs. John F. Perry, Earl G. Yonehiro, Harlan D. Root and others are exploring radioactive ferrous citrate as a cancer detecting agent—working on the thesis that radioactive iron, which combines readily with red blood cells, would escape through mucosal leaks in viscera, such as the alimentary tract—thus serving to alert the examiner of the likely presence of an occult lesion.

Obviously, it is to research developments that we must look for improved knowledge concerning cancer. There are extensive studies now going on in many countries of the world, which are focusing interest upon causes of cancer and upon ways of controlling cancer that has gotten out of bounds. On this latter score, I can only say that whereas there are chemical and hormonal agents which will control several cancers for a period of time, the panacea for which every cancer investigator has been looking—an agent which will suppress cancer permanently—still has not been found.

In the summer of 1928, I had the opportunity of hearing a message, written by King George V of England, read as prelude to the First International Cancer Conference. In effect, the King said: "I note with interest that your object is research, both into the cure and causes of cancer. No doubt in the last resort the discovery of the cause is the only certain and absolute means of cure. But I am glad that you have not ignored the practical side of the problem. Remembering the thousands of sufferers from cancer, I feel that if your discussions lead to advance in diagnosis, treatment, or even palliation of the disease, this Conference will have justified itself and earned the gratitude of mankind." What a great prophet King George V proved to be. Those words could well have been employed to invoke each and every International Cancer Conference which has been held in the meanwhile.

A few days ago, I had the privilege of hearing Mr. A. A. Heckman, Executive Director of the Hill Family Foundation, speak to a group of surgeons on the philosophy of philanthropy. In tracing how philanthropy came about in this country, Mr. Heckman alluded to the observations of Alexis de Tocqueville, who spent approximately nine months in this country approximately 125 years ago. In writing a few years later (1835) of Democracy in America, de Tocqueville said, "The Americans are the most peculiar people in the world. You will not believe it when I tell you how

they behave. In a local community in their country a citizen may conceive of some need which is not being met. What does he do? He goes across the street and discusses it with his neighbor. Then what happens? A committee comes into existence and then the committee begins functioning on behalf of that need and, you won't believe this but it is true, all of this is done without reference to any bureaucrat—all of this is done by private citizens on their own initiative." In essence, that is how this great movement of your Masonic Order came into being: appreciation of the need; recognition of the importance of the cause; agreement upon a course of action, and something which many cancer sufferers must have dreamed and hoped for has come into being. Hope has been defined as a dream of the waking state. For the resolution of many of our problems, we need dreamers who can and will translate their vision into resolute action. That is what you have done. In these terms we could call Joseph the world's first banker.

On the occasion of his third visit to our surgical clinic, Professor Komei Nakayama from Chiba City, Japan, to whose research on cancer I alluded earlier, brought his attractive and delightful wife Mrs. Wangenstein, knowing of their plans thought a dinner was in order for the second night of their three days' visit to us. Late in the afternoon of the day of their expected arrival, we were notified by Northwest Airlines that travel conditions over the Pacific had been very poor and that our guests would be delayed approximately forty-eight hours. Thereupon, Mrs. Wangenstein, being inventive in such matters as many of you, I am certain, have been on similar occasions, invited a number of family relatives in for the dinner. Approximately twenty-four hours after this switch of plans, Mrs. Wangenstein was notified by the airline that our Japanese guests would arrive but perhaps a bit late for dinner—a circumstance which made it necessary to replan the dinner guests. Later that evening, when we were seated at dinner, the Japanese professor felt called upon to tell a story. He indicated how tired Mrs. Nakayama was after spending several days en route without having had the opportunity to stretch out on a bed. He explained how he had persuaded Mrs. Nakayama to come to dinner over protests of great fatigue. Said the Professor, "Everyone seeks the ideal life. I have three recommendations: get an American home: the best;

at Chinese food: none better; get a Japanese life: works hard, and no discussion!"

Nan Fairbrother begins her warm book on Men and Gardens by quoting a wise saying to be found in a book of Chinese proverbs: "If you would be happy for a week, take a wife; if you would be happy for a month, kill your pig; but if you would be happy all your life, plant a garden." We identify the happiest state of man in a garden. There is here the Lord provided him initially with every means for his sustenance, enjoyment and pleasure. Everything went well until man ate of the forbidden fruit of The Tree of Knowledge in the midst of the garden and was driven forth "lest he reach out his hand, eat also of The Tree of Life, and eat and live forever." Long years later Rudyard Kipling in the *Glory of the Gardener* commented as follows:

"Oh, Adam was a gardener, and God who made him, sees
"That half a proper gardener's work is done upon his knees."

There are probably few people among us, who, when contemplating the punishment of toil, sorrow and grief meted out to our ancestors have not looked back wistfully upon that original blissful state. Let me only remark, if work is the curse of Heaven, how pleasant could its blessings be? Many early writers have succeeded in conjuring up in our minds pictures of the Garden of Eden, from which Man was driven out, as an alluringly enchanting place of picturesque formal gardens like those of Versailles. However, John Milton, who saw with the penetrating eye of good taste, describes the Garden of Eden in *Paradise Lost* as a place of rugged and natural beauty, and in *Paradise Regained* he speaks of it as "Nature's own work."

Such a garden is the nature of the gift which you have come today to offer to the University and the peoples of Minnesota. Let us all till this garden well—yes, on our knees with a spirit of dedication and affection for our fellowman, who stands in need of our help.

Service was the Great Master's last instruction to his disciples. Every man in the cancer fight carries a cross, and no adversary is so formidable as he who carries a cross. Let us not put in down. A few years ago, one of our local newspapers carried the report of the two small brothers who were crossing the street; the larger brother was struck down by a careless motorist. The small

younger brother carried his burden to the sidewalk. When willing hands offered to relieve him of the burden, the boy said: "He is not heavy; he is my brother." The weight of supporting this noble activity of your Masonic Orders should not be wearisome. In fact, some of us may come to bring our burdens there.

It is not out of line, I think, to believe that this Masonic Memorial Hospital will bring new hope to many, and healing to some cancer sufferers. This hospital, together with Clinical Research Facilities of the Veterans of Foreign Wars to be placed by its side, can come, I believe, to catalyze an action to speed the day when cancer will no longer reign as one of the captains of death.

For every school child the story of Cinderella and Prince Charming and how "they lived happily ever after" still holds an especial fascination. As children once, what did you and I think this phrase, which rolls so pleasantly and easily off our lips, meant?—Well, I no longer remember. Do you? In any case, no lasting impression remains of the kind of life which I then pictured for Cinderella and her Prince Charming. Experience always tempers one's day dreams. But I can tell you what I think now: I would say it means acceptance, appreciation and enjoyment of things as they are with hope, reinforced by effort, that they will be better. The new Masonic Memorial Hospital, provided by the beneficence of the Masonic Orders, potentiated in turn by the Research Facility of the Veterans of Foreign Wars and with your help and mine, should make the lot of cancer sufferers somewhat better in the State of Minnesota.

The Cinderella and Prince Charming relationships of life are few indeed. And in so grim an aspect of life as cancer, the only facets of interest that can command our continued concern and attention are the bonds of service and sympathy. These, moreover, are the only solvents capable of absorbing and dissolving the distressing ailments of this troubled universe. In the auditorium of the world, when will these soft and mellow influences, more readily felt than heard, come to replace the harsh and noisy clash of armor and the flash of guns? Social progress unfortunately is painfully slow in this world. However snail-like the growth of knowledge in the cancer field is, it is altogether likely that we shall conquer cancer before we can learn to live in harmony and peace with our neighbors.

Loeffler's Syndrome (Eosinophilic Pneumonia)

CATHERINE BURNS, M.D.
Albert Lea, Minnesota

PROFESSOR Loeffler, of the Outpatient Medical Clinic of the University of Zurich, in 1932¹ first described the syndrome that now bears his name. At that time he reported on eight patients who had mild or absent clinical symptoms associated with lung infiltrates resembling the shadows seen in early tuberculosis. Eosinophilia also was present, with a slightly increased sedimentation rate. He concluded that, "If it is a case of pneumonia, then it must be a very special form of it."

In a report in 1936, Loeffler² stressed the fleeting character of the lung infiltrate, noting, "The main symptom is the x-ray shadow, which is of indefinite location and of indefinite spread, of variable structure, either homogeneous or patchy. The shadows may, however, be sharply defined and either unilateral or bilateral." He set forth four criteria for diagnosis of this symptom complex, namely (a) a roentgen shadow in the lung, (b) the observance of its fleeting behavior, (c) the accompanying blood eosinophilia, and (d) only slight impairment of the general health of the patient.

He stated that all the symptoms were gone in a few days to two weeks in the majority of patients, but that the condition occasionally may become chronic. During the period of pulmonary symptoms, transitory x-ray shadows in the lungs appeared to be much more serious than the signs and symptoms of the patient would imply. Eosinophilia up to 66 per cent was noted. Fever was generally low grade, not more than 100° F, but it sometimes reached 103° F. There was an irritative cough productive of thin sputum containing eosinophils, the cough sometimes accompanied by wheezing. The only physical findings consisted of occasional mild friction rub, crepitant râles, vesicular breath sounds, and mild or absent dullness. After resorption of the infiltrate,

a fine fibrous star-shaped scar may remain on x-ray.

By 1940, a total of 105 cases had been reported. From 1940 to 1955, reports of another 130 cases have appeared in the literature. Many more unreported and unrecognized cases undoubtedly occur.

Loeffler's original work stressed the mild clinical course of the disease, but subsequent reports have included some cases of severe septic disease persisting from several months to periods up to seven years. Vines and Clark³ and Schwartz⁴ made detailed reports of two instances of serious disease of long duration in which treatment with ACTH and cortisone appeared to be life saving.

The cause of eosinophilic pneumonia is not clear. Loeffler first considered it related to the tubercle bacillus or possibly an "erythema nodosum of the lung." More recently he and his associates⁵ suggested *Ascaris* as an etiologic agent.

The theory of allergy seems to be the most generally accepted one at present. When the condition is chronic, it is often associated with asthma. Bacterial allergy has also been mentioned. Elsom and Ingelfinger⁶ reported two cases in patients with chronic relapsing brucellosis. Gregory⁷ reported on one patient whose condition differed from that of others only in severity; autopsy disclosed periarteritis nodosa.

Several authors have suggested that the name "Loeffler's syndrome" be reserved for the simple transient pulmonary infiltration originally described. Crofton and co-workers⁸ suggested the term "pulmonary eosinophilia" to cover the broad group and to reserve the term "Loeffler's syndrome" for the mild transient form. Their classification is as follows:

Group I. Simple transient pulmonary infiltration, or Loeffler's syndrome. This includes cases in which the pulmonary infiltrate persists no longer than one month, with fever not more than 100° F. and an eosinophil count of at least 6 per cent.

Group II. Prolonged pulmonary eosinophilia without

Presented at the Southern Minnesota Medical Association, Albert Lea, September 10, 1955.

asthma. This syndrome usually lasts two to six months. The symptoms may be rather severe and there may be recurrences after some months of remission.

group III. Pulmonary eosinophilia with asthma. Many asthmatics with more or less permanent eosinophilia may be placed in this group when they have intercurrent pneumonia. However, a number of cases are reported in which the pulmonary findings are shifting and apparently similar to Loeffler's original description.

group IV. Tropical eosinophilia. In 1943, Weingarten⁹ reported eighty-one cases of pronounced eosinophilia with pulmonary infiltrates that he observed in India. Other reports of pulmonary eosinophilia associated with parasites would fall into this group. Eosinophilia is present at the onset of the disease rather than in the third or fourth week, as in most allergic disorders. Treating the parasitic infestation relieves all the symptoms, including the pulmonary findings.

group V. Periarthritis nodosa. Patients in this group are usually severely ill when x-ray evidence of pulmonary infiltration is present.¹⁰

Because of the benign nature of this syndrome, extremely few cases have become available for pathologic study. A report from the Mayo Clinic¹¹ in 1946 gave an excellent description with illustrations of the pathologic findings in a case in which asthma also was present. The authors concluded that the appearance was that of organized pneumonia with large numbers of eosinophilic leukocytes.

Buckles and Lawless¹² reported that microscopic study of an operative specimen they removed for suspected carcinoma disclosed scattered fibrosis with extensive eosinophilic infiltration, periarthritis and arteriolitis with eosinophilia.

Faison¹³ expressed the theory that the pulmonic infiltration represents atelectasis. He made the following statement: "Virus pneumonia may resemble Loeffler's syndrome more closely than any other condition mentioned. Not only is there a close similarity in the pulmonary changes demonstrated by x-ray examination, but there is also, in both conditions, a striking disproportion between the physical and x-ray findings. Patients with virus pneumonia, however, do not have eosinophilia, and the x-ray densities ordinarily do not shift."

The treatment has varied widely in the cases reported. Prior to the widespread use of antibiotics, such agents as autogenous vaccines, vermifuges, organic arsenicals, iodides, blood transfusions and epinephrine were used. More recently,

administration of most of the antibiotics, antihistamines and steroids has been reported.

The most consistent results have been obtained with ACTH and cortisone. One patient reported on by Herbert DeVries and Rose¹⁴ showed dramatic clearing of the pulmonary lesions and eosinophilia in forty-eight hours of ACTH therapy. Mark¹⁵ reported the use of epinephrine, blood transfusions and cortisone either singly or in combination in the treatment of twenty-three patients with pulmonary eosinophilia. Andrell and associates¹⁶ stated that a thirty-two-year-old woman who had had bilateral pulmonary infiltration with severe cyanosis and dyspnea for seven weeks showed dramatic improvement after three days of ACTH therapy. Schwartz⁴ made a detailed case report of a sixteen-year-old girl with an illness of eighteen months' duration who responded in one week to cortisone treatment. A relapse necessitated a second course of cortisone one week later.

One other case report by Vines and Clark³ is most interesting. A forty-one-year-old woman with a two and one-half months' history of severe pulmonary disease accompanied by asthma made a dramatic recovery after treatment with ACTH. She had received penicillin, aureomycin, streptomycin, chloromycetin and sulfonamides, and had been in an oxygen tent prior to ACTH therapy. After the second day of treatment with ACTH, the oxygen tent was no longer necessary and she was sent home sixteen days after use of ACTH was started. However, one week later, the x-ray again showed clouding, so she received ACTH for twelve more days. Her eosinophil count persisted at 12 per cent but all x-rays were reported normal one year after treatment.

Report of Case

A forty-six-year-old white woman came under my care on September 27, 1954, because of a severe cough, chills, fever and thoracic pain of ten days' duration. She was extremely pale and noticeably dyspneic. Her temperature was normal, and the only physical findings were expiratory rales at the base of the right lung.

Past history revealed "inflammatory rheumatism" at the age of twelve, "lung fever" every winter as a child, a cholecystectomy in 1945 and pneumonia three times since 1946. The only history of allergy was hives once at the age of twenty after she ate quantities of strawberries.

Leukocytes numbered 8,900 cells per cubic millimeter of blood; the value for hemoglobin was 13.7 gm. per 100 ml. Thoracic roentgenograms showed increased density of the right lower lobe (Fig. 1).

The patient was given one intramuscular injection

of 100 mg. of tetracycline, followed by 500 mg. of the drug given orally every six hours for the next twelve days. At that time, she had not improved clinically and had lost twenty-two pounds since the beginning of her

lungs continued to show increased density on the right and a larger area on the left (Fig. 2).

During the next five weeks, she received 1 gm. dihydrostreptomycin plus 10 mg. of Chlor-trimeton daily

Fig. 1. (Upper left). September 27
Fig. 2. (Upper right). November 12

Fig. 3. (Lower left). January 17
Fig. 4. (Lower right). January 20, after forty-eight hours of cortisone therapy.

illness. The sedimentation rate (Westergren method) was 102 mm. during the first hour and roentgenograms showed increased density in the lower lobes of both lungs.

She was then given 400,000 units of penicillin and 0.5 gm. of dihydrostreptomycin daily. After four injections, severe local reactions occurred, so 10 mg. of chlorphenpyridamine maleate (Chlor-trimeton) was added to each injection. This therapy was continued for six days and had to be stopped because she began to get a localized reaction to the drugs in spite of the antihistamine.

The next medication tried was erythromycin, which was given in doses of 200 mg. every six hours for the next two weeks. At this time the leukocyte count was 7,600 and the sedimentation rate was 100 mm. She was raising considerable amounts of yellow mucoïd sputum. She had not lost any more weight and felt clinically somewhat improved. However, the x-ray studies of the

She appeared to improve both clinically and by x-ray findings during this time. The sedimentation rate decreased to 50 mm, but the thoracic films continued to show fairly large zones of increased density on both sides. On December 10, the leukocyte count was 9,300, and the differential count showed 47 per cent polymorphonuclears, 28 per cent lymphocytes, 23 per cent eosinophils and 2 per cent basophils. She was feeling much improved, had minimal cough, and had not had any fever for eight weeks. She had evidence of rather severe local reactions to the dihydrostreptomycin, which had developed in the last few days of therapy.

During the next ten days she was treated with postural drainage, rest in bed and vitamins with no noticeable change in her condition. A trial of 8 mg. of Chlor-trimeton given every eight hours for the next two weeks did not alter the situation. On December 30, the sedimentation rate was 77 mm, the leukocyte count was 6,000, and the differential count showed polymorpho-

nuclears 41 per cent, lymphocytes 55 per cent, eosinophils 3 per cent and basophils 1 per cent. Thoracic films displayed increased density in the right middle lobe and left lower lobe.

She was hospitalized on January 15, 1955, for further laboratory work and a trial of cortisone. Results of a Mantoux test and agglutination tests and cultures for *Brucella* were negative. Several stool specimens were negative for ova and parasites. The sputum showed no eosinophils or fungi. The sedimentation rate was 84 mm. Blood counts and urinalysis were normal. Roentgenograms of the thorax showed decreasing density on the right and increasing density on the left in the subclavicular region (Fig. 3).

Administration of 200 mg. of cortisone per day was begun on January 18. Two days later, the thoracic films showed dramatic improvement. The clouded zone on the left was 50 per cent less dense and the clouded zone on the right was only a faint shadow (Fig. 4). Roentgenographic improvement continued and no new areas of increased density were noted. She received 200 mg. of cortisone daily for twelve days, after which the dose was gradually reduced to 50 mg. daily. Thoracic roentgenograms on February 11, 1955, showed both lung fields to be completely clear. Use of cortisone was discontinued by the next week. The sedimentation rate gradually returned to normal in three months. The patient has had frequent normal thoracic roentgenograms since then and has remained clinically well to the present time.

Summary

A case of Loeffler's syndrome associated with prolonged pulmonary eosinophilia without asthma has been presented. After three and one-half months of failure of therapy with most of the antibiotics, a dramatic response was obtained within forty-eight hours after use of cortisone was begun. Administration of cortisone was continued for a total of three weeks, and the patient has continued to remain well to the present time.

ART AS WELL AS SCIENCE OF MEDICINE IMPORTANT

A thoughtful reminder from a Toledo, Ohio, physician has emphasized that the "art" of medicine should not lose its important place as a result of the giant strides achieved in the "science" of medicine.

Both art and science play their respective, indispensable roles, said Dr. Clarence E. Hufford in a recent issue of *Radiology* (March, 1957).

Some of Dr. Hufford's other conclusions:

... The many inroads being made on private medical practice, of social and economic origin, must make us ever more cognizant of our obligations to the patient. The radiologist who considers himself a medical clinician must exercise the functions of the clinician. In no sense

does meticulous care in radiographic procedure lessen his clinical obligation.

... The sacred patient-physician relationship, which has been stressed in recent years, must still be guarded most religiously in our daily practice if its significance is to be maintained. The pressures of modern medical practice, as encountered in the field of radiology, continuously infringe on the time available for expression of personal interest in our patients.

... The zeal of our forebears in protection of the public against the charlatanism of mere picture making will have come to naught if the warmth of medical care is lost to our specialty.

Continuation Study

Treatment of the Nephrotic Syndrome with Malaria

A. SIGRID GILBERTSEN, M.D.
Minneapolis, Minnesota

THE term nephrotic syndrome refers to a clinical picture characterized by edema, albuminuria, hypoproteinemia and hypercholesterolemia. Diagnosis of the nephrotic state, however, does not necessarily imply recognition of its etiology in any given patient. In the patients who received malaria therapy, attempts were made to

temia, recent infection, or electrolyte abnormalities. When administered to suitable candidates in doses of 100 to 200 units per square meter of surface area per day for ten to fourteen days, corticotrophin produces remissions in 60 to 80 per cent of the patients treated; however, remissions lasting twelve months or longer are seen in only 20

rule out certain specific causes of the nephrotic syndrome including syphilis, diabetes, amyloidosis, disseminated lupus erythematosus, thrombosis of the inferior vena cava or renal vein, and the toxic nephroses. Lipoid nephrosis and chronic glomerulonephritis have been the primary diagnoses in the patients of the present series. Since these latter two diseases are difficult to differentiate, the less specific term *nephrotic syndrome* is preferred.

Therapy of the nephrotic syndrome is no less difficult than precise diagnosis. Steroid therapy is the generally accepted treatment of choice in patients who do not manifest hypertension, azo-

to 43 per cent.¹⁻⁸ It is apparent that many patients respond only transiently to steroid therapy, demonstrate contraindications (especially hypertension) to the use of steroids, or become refractory to steroids as well as other forms of treatment. It is with these patients in mind that the use of malaria therapy in the nephrotic syndrome has been explored.

Febrile illnesses such as measles^{9,10} or hepatitis¹¹ occasionally have been observed to have dramatic effects on the course of the nephrotic state. Fever therapy has been attempted using induced measles; lack of control measures and the danger of encephalitis have prevented widespread use of this method. Typhoid vaccine has not been effective.¹² The ease of control and the rarity of complications with *Plasmodium vivax* make the use of malaria a reasonable approach to the therapy of the nephrotic syndrome.

Read before the Continuation Course in Recent Advances in Internal Medicine, University of Minnesota, Minneapolis, February 13, 1956.
The malarial blood used in this study was furnished by the Laboratory of Tropical Diseases, United States Public Health Service, Columbia, South Carolina.
Dr. Gilbertsen is an Instructor in Medicine, Department of Medicine, University of Minnesota Hospitals.

TABLE II. CHANGES OBSERVED WITH MALARIA THERAPY IN THE NEPHROTIC SYNDROME

During or Immediately Following Malaria	Late Changes
1. Water diuresis	1. Gradual restoration of serum albumin
2. Sodium diuresis	2. Gradual disappearance of urine albumin
3. Decline in blood pressure	3. Gradual decline of ESR
4. Rapid decline in serum cholesterol	
5. Transient fall of hemoglobin	
6. Transient rise of BUN	
7. Decrease, but not disappearance, of urine albumin	
8. Little or no change in serum albumin	

A summary of the literature on malaria therapy in the nephrotic syndrome appears in Table I. The first reports by Gairdner¹³ and by Byrne¹⁴ in England appeared in 1952. Subsequently, several other reports have appeared.¹⁵⁻¹⁸ Recently Gairdner and Shute¹⁹ reported fifty-three additional patients treated in England whose cases previously had not been reported, making a grand total of seventy-six cases reported to date.

These patients are most conveniently grouped according to the presence or absence of azotemia and according to whether complete or partial remission occurred. Partial remission indicates either incomplete loss of edema or a remission persisting three months or less. Of the nineteen patients with azotemia, none obtained a complete remission; only five were reported to show favorable response. Approximately one-half of the patients without azotemia manifested a favorable response to malaria.

Inoculation and Management of Malaria

Malaria therapy has been attempted in ten patients with the nephrotic syndrome at the University of Minnesota Hospitals and Ancker Hospital. Clinical malaria was produced in nine. Six of these patients have been reported in detail elsewhere.¹⁸ Vivax malaria was used exclusively because this form is not associated with cerebral malaria or blackwater fever, and it may be readily terminated.

Intravenous inoculation of blood containing viable parasites was used in preference to mosquito inoculation because of the lower relapse rate associated with the former.

Using chloroquin as the only antimalarial agent, relapses with intravenous inoculation are 0.2 per cent as compared to 20 per cent with mosquito inoculation.²⁰ The incubation periods varied from twenty-four hours to nine days. Two patients were

inoculated twice to produce clinical malaria; one patient did not develop clinical disease although inoculated three times. Chloroquin was used to terminate fever in all patients.

The patients were allowed to experience between one and thirteen pyrexial episodes. The indications for terminating malaria were the onset of diuresis in two patients, prostration in two, hypotension in two, and clinical deterioration in two. In one patient fever was arbitrarily stopped after thirteen febrile periods. The fever was usually quotidian at first and then became tertian.

Clinical Material

All nine patients in whom malaria was induced had been treated previously with conservative measures including bed rest and salt restriction. Five had also received steroid therapy, and three patients had been treated with nitrogen mustard. The duration of symptoms prior to therapy was from one to twenty-two months. The age range was seven to sixty-seven years.

Hypertension was a feature in five patients. Azotemia or electrolyte abnormalities or both were present in three patients. Of the six patients who did not have azotemia or electrolyte disturbances, excellent remissions were obtained in five following malaria therapy.

Results

In the patients in whom remissions were obtained with malaria therapy, certain changes occurred with regularity. These changes are summarized in Table II. The sodium and water diuresis often occurred immediately following termination of malaria, but in two patients began during malaria therapy. A decline in blood pressure, seen in all patients, was especially striking in those who had hypertension initially. A precipitous fall in serum cholesterol was seen in all patients during therapy whether or not a remission occurred. A transient fall in the hemoglobin and a rise in blood urea nitrogen (BUN) during therapy was the rule; return to normal hemoglobin level occurred within a month. Albuminuria regularly decreased but did not disappear at the time of malaria therapy. Little or no change in the serum albumin levels was seen during treatment.

Restoration of the serum albumin to normal, disappearance of albuminuria, and decline to normal of the erythrocyte sedimentation rate occurred

gradually over a period of several months. The changes in blood pressure, serum cholesterol, albuminuria, serum albumin, and erythrocyte sedimentation rate following malaria therapy are in contrast to the behavior of these indices following steroid therapy.

Table III illustrates the immediate and the later changes produced by malaria therapy in the six patients without previously existing azotemia or electrolyte abnormalities. Three of these patients initially had significant hypertension. Four had received steroid therapy previously, and two had been treated with nitrogen mustard. An excellent response was obtained with malaria in five of the six patients. The weight loss in each patient was commensurate with the magnitude of the diuresis; this amounted to 60 pounds in one patient. Patient L. H. did not have a favorable response. She had minimal edema prior to therapy, and the serum albumin was not remarkably low (2.4 gms. per cent); with malaria she lost 15 pounds in weight and lost the edema, but no striking diuresis and little change in the albuminuria or the serum albumin occurred.

The change in blood pressure is shown for each patient. All patients who were hypertensive initially became normotensive during malaria therapy. In one patient, normotensive prior to therapy,

the fall in blood pressure was such that support of the circulation with vasopressor substances was necessary for several days.

The magnitude of the cholesterol decline during therapy is shown for each patient. Although the disappearance of albuminuria occasionally occurred as early as two months after therapy, albuminuria usually decreased slowly over a period of several months. The restoration of normal serum albumin levels occurred as early as one month after therapy, but the serum albumin usually increased slowly over a period of several months. The sedimentation rate did not return to normal in any patient before nine months.

Three of these six patients have enjoyed sustained remissions for seventeen, twelve, and eight months, respectively. All three are free of edema and have normal blood pressures. One patient has no albuminuria; the other two show a trace. The serum cholesterol is normal and the serum albumin is 3 gms. per cent or greater in each.

Of two patients who relapsed, the first had a sustained remission for twenty months and was seemingly entirely well during that time. With relapse of the nephrotic state, the previously existing hypertension did not recur. She has recently obtained a good response to bed rest and

alt restriction, measures which were not effective two years ago. The second relapse occurred in a even-year-old boy who was ill almost two years prior to malaria therapy. Although he obtained good clinical remission, including relief of hypertension, the serum albumin did not rise above 1.9 gms. per cent. Relapse occurred three and one half months after therapy, but hypertension did not recur. He has subsequently responded well to ACTH, measles, and cortisone.

The glomerular filtration rate, as measured by the clearance of insulin and the renal blood flow, is measured by para-amino hippurate clearance, were ascertained before therapy and again after the cessation of diuresis in two of the patients who obtained good responses to malaria. Each patient manifested improvement in both renal functions from low values prior to therapy to near normal values after diuresis.

The dramatic responses observed in the patients who had no azotemia or electrolyte disturbance are in contrast with the responses in the three patients with azotemia or electrolyte deviations or with both. The cases of these three patients are summarized in Table IV. Malaria therapy was well tolerated by patient C. C., although the BUN was 58 mg. per cent. However, no favorable response was observed. Subsequently he remained refractory to nitrogen mustard and eventually died of uremia. The other two patients had rapidly progressing clinical courses; unfortunately, steroid therapy was contraindicated in one patient by the presence of severe hypertension and by the history of a perforated peptic ulcer in the other. Each of these latter patients manifested

a low carbon dioxide (CO₂) combining power remarkably disproportionate to the BUN. Malaria was tolerated poorly by both patients; it is possible that malaria hastened the demise of both. In view of this experience, azotemia and electrolyte abnormalities, particularly a low CO₂ combining power, are believed to represent absolute contraindications to malaria therapy.

Mechanism of Action of Malaria

The mechanism of action of malaria fever in inducing remission of the nephrotic state remains obscure. Fairley and Bromfield,²¹ in 1933, observed that patients with malaria regularly exhibit a marked decline in serum cholesterol associated with decreased hemoglobin and increased blood urea levels. Gairdner¹³ postulated that the lowered serum cholesterol initiates the response in some unknown way. Byrne¹⁴ considered that malaria works by way of adrenal stimulation. This latter hypothesis receives some support from the observations of McCall and Singer²² who found increased urinary corticoid excretion in one nephrotic child with fever associated with peritonitis.

The possibility also exists that malaria therapy acts primarily through a change in the immune mechanisms of the nephrotic patient. Gairdner and Shute¹⁹ followed the electrophoretic patterns of serum proteins in several patients and found an increase in gamma globulin levels about 10 days after the onset of malaria. The alpha globulin returned to normal only after several months. Additional observations and studies will be necessary before these problems are clarified.

Summary

Malaria therapy was attempted in ten patients with the nephrotic syndrome; clinical malaria was produced in nine patients. Of the six who did not have azotemia or electrolyte deviation, five sustained excellent remissions. The remissions occurred despite the presence of hypertension or refractoriness to other forms of therapy. When hypertension was present, relief followed a course of malaria. When relapses occurred, the patients then responded to forms of treatment which previously had been ineffective.

Three patients are in remission eight months, twelve months, and seventeen months after malaria therapy. Relapses have occurred in two patients, twenty months and three and one half months after treatment.

In the three patients with pre-existing azotemia or electrolyte abnormalities or both, malaria was not of benefit and possibly hastened the demise of two. Azotemia and substantial electrolyte deviations, especially low CO_2 combining power, thus, probably represent absolute contraindications to malaria therapy.

Addendum

The patient, L. H., shown in Table III as the only patient without azotemia or electrolyte abnormalities who did not respond favorably to malaria therapy, has recently been shown by biopsy to have primary amyloidosis. Thus the patient has improperly been included in this series of cases of lipoid nephrosis and chronic glomerulonephritis.

Remissions in patient M. H., I. McL., and L. E. have been sustained for twenty-two months, seventeen months, and thirteen months, respectively.

Tumor Conference

Section Editor

CLAUDE HITCHCOCK, M.D.

CASE STUDIES, ST. BARNABAS HOSPITAL

Case 1.—This fifty-six-year-old white man was presented to the Tumor Conference with a lesion on the shaft of the penis about $1\frac{1}{2}$ cm. in diameter. The lesion included a portion of the corona and extended back on the shaft of the penis and was well circumscribed with a central ulceration that contained purulent material. The initial impression of this lesion from superficial examination was that of a chancroid.

The patient first noted the appearance of the ulcer about six months previously and denied sexual intercourse during the past month, as well as any outside sexual activity. Examination of the patient revealed the Wassermann to be negative, and a biopsy of the lesion was reported as a squamous cell carcinoma.

After discussion regarding the type of therapy to be applied, the tumor board recommended an exploration of both inguinal regions for lymph nodes, and if none were found the primary lesion on the shaft of the penis was to be treated with irradiation therapy. Treatment with radium was also recommended.

Discussion: Carcinoma of the penis varies greatly in incidence from one country to another. The incidence in the United States is very low, but the incidence in such countries as China, Siam, Java, and Europe is relatively high. In some European countries as many as 5 per cent of all carcinomas in the male are represented by carcinomas of the penis. Although many suggestions have been made regarding the relationship of carcinoma of the penis to circumcision, it is still not definitely established that ethnic factors are of equal importance to factors of simple cleanliness.

The extension of these lesions is upward on the shaft of the penis to the suprapubic lymph glands and then laterally to superficial and deep nodes in the region of the inguinal ligament. Adequate treatment for carcinoma of the penis requires bilateral and thorough inguinal-iliac lymph node dissections. The primary cancer can be treated in one of several ways. Application of superficial roentgen therapy has given good results, but it is emphasized that the therapy must be well fractionated and the treatments applied in a careful manner. The superficial surface application of radium by means of radium molds has been used for this type of carcinoma, but great skill is required to assure good results. The standard method of treatment for carcinoma of the penis is amputation of the organ allowing at least $1\frac{1}{2}$ cm. of clear tissue proximal to the lesion; surgical excision has been found of much value in completely eradicating the primary tumor. The safest and surest method of controlling metastases would be the performance of a bilateral inguinal-iliac lymph node dissection even in the absence of palpable nodes.

Case 2.—A fifty-four-year-old married woman came to the Tumor Conference complaining of pain in the right forearm that had its onset during October, 1956. She described this pain as aching and occasionally pounding

in character, with a feeling of tightness in the right forearm. The pain was of an intermittent quality but frequently was excruciating and disabling. Physical examination revealed the right arm to be considerably swollen in the upper two-thirds. The skin was rather hard but there was no color change and no local heat. The entire right arm was edematous below the region of the tumor and there was some limitation of motion at the wrist, elbow and finger joints.

Roentgenograms of the right shoulder and humerus revealed an extensive osteolytic process involving the proximal half of the shaft of the right humerus and extending into the head of the humerus. The cortex was broken through in several areas and some areas of sclerosis were noted but there was no true bone production identified. Associated with the bony changes was a large soft tissue mass which extended particularly up into the region of the axilla. A biopsy of the lesion was performed and the diagnosis of a reticulum cell sarcoma was made. The patient was then operated upon with a formal scapulo-humeral disarticulation of the right upper extremity. During surgery there was no reason to believe the lesion had spread beyond the site of the upper end of the humerus, and the lines of resection were clean and free of any tumor. The patient did well postoperatively and left the hospital on her eighth postoperative day.

Approximately two months following surgery, however, the patient developed a mass in the upper anterior chest wall on the right side. This mass was biopsied with the resultant diagnosis of a recurrent reticulum cell sarcoma in the stump of the pectoralis major muscle. The patient was started immediately on roentgen therapy and was doing well as of April 18, 1957, following a total of 2700 roentgens already received.

Discussion.—The therapy of choice for reticulum cell sarcomas of the bone, particularly when localized to one bone at the time of initial therapy, is surgical removal. However, it must be realized that these tumors do invade from the bone outward into surrounding tissues, and can extend for relatively great distances in the fascial planes and along the blood vessels and lymphatics as they course away from the area of involvement. Undoubtedly, in this case, the residual tumor found several months after the primary disarticulation was due to small emboli of tumor present in the pectoralis major muscle by direct extension from the primary mass.

Roentgen therapy is an important adjunct in the therapy of these tumors. This type of cancer is highly radiosensitive, and, particularly in the case of metastases, prolonged and significant palliation can be effected. Even in the presence of a distant metastasis with a primary as presented here, surgery of the type performed would probably be the initial therapy of choice. It is beneficial to remove from the patient the large mass of tissue that would probably respond somewhat more poorly to roentgen therapy than smaller more circumscribed lesions. The combined approach of surgery and roentgen therapy in this patient would seem to be highly desirable.

LEO G. RIGLER

On June 30, 1957 Dr. Leo G. Rigler left the University and the state of Minnesota to accept the post of senior consultant in charge of graduate medical education in radiology at the Cedars of Lebanon Hospital in Los Angeles. He will also be a visiting Professor at the University of California, Los Angeles.

Leo Rigler's superb contribution to medicine and medical education over the past thirty years is self-evident to a degree that it scarcely requires comment, yet there are a few points that may deserve special emphasis. One of his great faculties has been that of integrating radiology with medicine, making it understandable to the physician and ever of greater value in practice. Rather than promoting the segregation of radiology on a far mountain top of mathematics and physics, he has steadily succeeded in showing how well it complements information which may be gained about the patient by other methods. His attitude toward radiology in medicine has consistently been wise and tolerant, recognizing its tremendous potential when properly employed and its limitations when used too narrowly.

It seems quite likely that Leo Rigler's broad wisdom in medicine is based not alone on his inherent qualities of mind but partly on his early experience. Many are unaware that after graduation from the University of Minnesota Medical School in 1919 followed by an internship at the St. Louis City Hospital, he spent a very active period as a family physician in a small community in western North Dakota. He often speaks of this background with genuine appreciation of its later effect on his teaching of medical students and his whole contact with the medical profession. It is also noteworthy and often unrecognized in respect to its impact on the unfolding of his subsequent career, that he next devoted himself to internal medicine, returning to the Minneapolis General Hospital as a resident under Dr. Henry Ulrich. It was during this period that he saw the tremendous significance of radiology, still a young science, for medical diagnosis, and that his interest became fixed in a career in this specialty.

It may be worthwhile to contemplate a further the factors responsible for his very great stature as a teacher and scientist. Quite apart from his personal warmth, enthusiasm, and lightful sense of humor, he has demonstrated remarkable ability in bringing scientific radiology to medical students and physicians. This is in part due to his simple and logical method of presenting his information and ideas—also to his success in integrating radiology with the basic sciences on the one hand and with clinical phenomena on the other. His use of topographic anatomy and the excellent manner in which he illustrates it for students, his understanding of pathological changes in relation to radiological findings, and his ability to correlate both with clinical signs—these are some of the reasons why he has won such a justly deserved worldwide reputation as a great teacher.

We respect but we must all keenly regret his decision to leave the University, at the same time saluting his fine achievements and wishing him the utmost success and happiness in his new endeavor.

C. J. WATSON, M.D.

THE UNIVERSITY—THE MEDICAL SCHOOL—SCHOLARSHIP

The academic year is drawing to an end, and this University presents another group of young men and women qualifying as Doctors of Medicine. These individuals have been the participants in a magnificent social privilege. As a reward for ability they were selected from a large list of candidates to enter a great university for the purpose of preparing for a medical career. Medicine has long occupied an honored position in the university. The first and oldest university in Europe, the University of Salerno, started a medical school around the year 1000 A.D. Our own country from its earliest days has always respected the place of the university in its culture with the clergyman and the physician occupying

Reprinted by permission from the *University of Minnesota Medical Bulletin*, June 1, 1957.

tions of dignity and honor in the community. The purposes of a university in the mid-twentieth century are complex. Fundamentally, according to Whitehead, "the proper function of university is the imaginative acquisition of knowledge." The faculty should "wear their learning with imagination." The student should probe the past, and acquire a contemporary concept of medical science with enthusiasm and in a spirit of excitement. His teachers must not only master knowledge of the present but should push beyond the horizon creating new knowledge, thus contributing to the general welfare and happiness of man.

The Medical School at the University of Minnesota in a relatively short period of time has assumed a position with the best in the United States. The faculty has been possessed with imagination and enthusiasm. A documentation of their creative achievements would be boastful. But a fair and sympathetic administration has recognized their accomplishments. Standing in the midst of the University are modern laboratories and engaged hospital facilities. But the heart of a university, or of any professional school, is the faculty-student relationship. Without this bond, buildings are just so much dust.

The prospective students of medicine have always been carefully selected, and rightfully so, since the physician's responsibility to his fellow man is direct and exacting. The selection has been based primarily upon ability and character. A student who selects a career of medicine must be dedicated. The training demands the utmost in self-discipline, and the course is long and expensive. Unfortunately, many qualified young persons cannot select medicine because of the financial barrier. And equally unfortunate is the student who cannot give of his best when in Medical School because he must weary himself with outside employment.

Members of the faculty, graduates of the Medical School, and many friends have long recognized the need for scholarships to aid the capable student who would otherwise not enter medicine, or to help those individuals in school who were seriously handicapped by financial needs. This need for scholarships was one of the basic reasons for organizing the Minnesota Medical Foundation. Through the efforts of Dr. Donald Cowling, Dr. Owen Wangenstein, Dr. Karl Anderson, and many others, a modest but meritorious scholarship

program has been started. Generous contributions have come from physicians, industry, medical organizations, and grateful lay people. The philosophy of the Foundation in awarding the scholarships has been two-fold. First, awards have gone to individuals who have demonstrated scholastic ability, and who at the same time have presented evidence of financial need. Second, scholarships have been awarded to those students whose financial needs have been so severe that they have not had a fair chance to demonstrate their intellectual abilities. The pursuit of scholarship demands a certain modicum of leisure. The frustrated, fatigued and worried student, devoid of adequate financial resources, simply cannot do good work. In many instances, financial help to such persons has been most gratifying, and has resulted in notable improvements in the student's class standing. The Foundation has not embarked upon a program of loans to needy students. The management of such a program would require a larger fund and an increase in staff. Furthermore, the University does have a loan fund available to students of medicine.

The University of Minnesota and the Medical School are proud of their heritage. The present faculty and the students will continue to uphold the high standards of scholarship. It is the continuing hope that no worthy student shall be denied the privilege of studying medicine because of financial want, or that any student shall fall by the wayside because of finances. The Foundation will not only continue the scholarship program, but will do so on a broader scale. An endowment fund that will perpetuate the program is urgently needed, and should occupy the attention of all the members and of their friends.

WESLEY W. SPINK, *President,*
Minnesota Medical Foundation

CALENDAR HISTORY

The big switch, in 1752, of England and America from the Julian to the Gregorian calendar and the resultant loss of eleven days is duly chronicled by Benjamin Franklin.

Franklin, generally credited with introducing the calendar as we know it today in America, in his thorough and painstaking way did not let this change pass unnoticed. He devoted most of his 1752 edition of *Poor Richard's Almanac* to the

Fourth in a series of editorials on calendar history.

calendar. He traced its origin and development, the various ways of computing time and the reason for the sudden alteration in dates. His readers were well aware there was more to making a calendar than merely printing names and numbers on paper.

Current periodicals of the time shed some light on the conflicts caused by the institution of a new calendar and the jump from September 2 to September 14.

An indignant writer to *Gentlemen's Magazine* (London, Sept., 1752) lets go with some sharp criticism of the shift.

A Mr. R. R. asks the publication "to settle my affairs or I shall run mad or break my heart."

R., who went to bed on Wednesday, September 2, and woke up Thursday, September 14, writes:

"Have I slept away eleven days in seven hours? I don't find I'm any more refreshed than with a common night's sleep."

He protests the loss of his own birthday since he was born on September 13, as well as the birth-dates of saints of the Church and other notables celebrated in this period.

Getting to the real point of his letter, Mr. R. recounts in a less humorous manner:

"I have solicited the most amiable of her sex for five weeks. She seemed to laugh at me, although my fortune is equal to her own, but at last she fixed the day, September 10 and [apparently to clinch the deal] gave me a bond of 10,000 pounds for the performance.

"I have consulted my lawyer . . . and he says the date 1752 is fixed to the document and it won't do for next year . . . so my 10,000 pounds is not worth 10 pence.

"A fine affair . . . a man must be cheated out of his wife by a parcel of mathematicians and almanac makers before he has her . . . a new form of divorce, even if parliament did do it."

So writes the choleric Mr. R.

Others in the *London Magazine* write in similar style, protesting confusion of records, the ruin of rental and leasing arrangements and utter consternation in their attempts to run a normal business in a month with the center chopped right out.

Mr. Roger Plowland writes to this publication about his problem. Concerned over the loss of eleven days, Mr. Plowland finds it is "greatly puzzling all the folks in our neighborhood and

I learn, when I go to the market, that others in as great a bother about them as ourselves."

He claims all the "almanac maker" tells is that the calendar jumps from September 2 to September 14. "This is all the account given us of the eleven days we are hunting for, but of which we in the present have lost the scent. Eleven days have been annihilated," he reasons.

Leases, rents and all business is fouled up, Plowland goes on. He doesn't care what lawyers, astrologers and conjurers have to say, "even the parson of our parish may say to the contrary," but he feels that provision should have been made so that "the business of October may have gone on immediately without interruption."

In addition to these literary objections, there were also more pronounced demonstrations. Disappointed tenants, shareholders and tradesmen who felt cheated out of money or goods through the sudden calendar manipulation, made known their state of mind more violently.

Street fights and riots arose over the switch, and unchronicled perhaps are countless brawls in inns and wine shops between proponents and adversaries of change.

But life and the calendar survived.

Brown and Bigelow

CONFESSIONS OF A HOBBYIST

Cabinet-Making

I was forty-five years old when I started serious cabinet-making. Until then, I had done occasional rough carpentry—the kind of thing one does with old packing-boxes, but precision work was new to me. I began acquiring wood-working machinery—first a circular saw and jointer, then, gradually a lathe, drill-press, sander, band-saw, and, last of all, a spindle shaper. It was some time before my shop was complete; a schoolmaster has to save up for things like that, and the machines came one at a time. Also, I inherited some fine hand tools. The use of these things was learned the hard way, from books and from bitter experience. Some good wood got ruined, and occasionally I had a minor accident, usually from an infuriated screwdriver or some such innocuous weapon, because I was too scared of the machines to get anywhere near the blades. One of the first things

Fourth in a series of editorial's on hobbies.

to be learned is that working with tools is labor, sweat, and blisters unless they are sharp, and that it takes both skill and patience to get the right edge on a plane or chisel, or to file a saw.

Of course, I had to start with something too hard. It was a maple butterfly table, from plans I had seen in a magazine. That was an education in itself. The turned legs were pretty awful, but the mortised and pinned joints came out rather well. I learned to my sorrow that maple is very hard wood, indeed! But, gradually, I did progress so that I could do passable turning, make honest, if not perfect, mortised joints, and manipulate hot cabinet-maker's glue; our old commercial furniture was gradually replaced by mahogany and maple pieces. These might not bear minute inspection, but they are well enough made to outlast me and my children.

The hard part is finding good designs. Unfortunately, I seem to be an artisan more than an artist, and while I can recognize and appreciate good proportions, I can't seem to create them. My neighbor and friend, the late Lindley Hosford, was a life-saver. If I wanted to make a sideboard or a chest of drawers, he would make a sketch, beautifully proportioned, and then I'd take over. Some of the pieces were maple, and if there is any meaner wood to work with than birdseye maple, I have yet to find it. Others were mahogany, and some millwork was pine. There are unexpected advantages in having a woodworking shop in the house. A small boy neighbor amused himself by kicking out some of the turned spindles in my porch rail, and I had merely to go upstairs and turn out a few spares for replacement.

People always seem to be interested in the cost of this hobby. I kept careful account of every cent spent for machinery, tools, hardware, lumber and glue. At the end of five years, I put conservative valuations on the pieces of furniture I had made, and to my pleased surprise, the two totals almost balanced and—I had the shop for my labor. I still have it, though I am not making large pieces any more. I manufacture a few picture frames, or turn a few bowls. One's interest in woodworking doesn't die.

JOHN de Q. BRIGGS

THE PRESERVATION OF BOOKPLATES

The first article in this series told of the 500 years of bookplate history; the second told of collecting and exhibiting. Prized collections are preserved in various libraries of cities and colleges. In 1938, a booklet of ninety pages, entitled "A Census of Bookplate Collections in Public, College and University Libraries in the United States," was prepared by Clara Therese Evans and Carlyle S. Baer and published in Washington, D. C.

In the foreword to this list, Louis J. Bailey, Chief Librarian of the Queen's Borough Public Library, New York City, wrote:

"Good collections should be given only to institutions that can adequately care for them. . . . Bookplate collections are no exception. One of the great values of this Census is that it will afford knowledge of what collections have been assembled and preserved, where they are, the type of material gathered, how they are cared for and their availability for study and consultation. Perhaps it will also call to attention the emphasis necessary on classification of bookplates, methods of preservation and use, and forms of indexing or cataloguing to make ready consultation possible. These should not be unconsidered trifles, if any collection is to serve a good purpose and be worthy of proper care and extension. Libraries seem the natural depository for bookplates which are a part of book lore; but, at that, considerable care in choosing must be taken so that only those libraries will be selected where care, study and exhibition are adequately provided. Something more than mere storage is necessary. . . . Libraries are now providing exhibit space for their rare and interesting possessions as never before."

The most famous collection of bookplates is that of the late Sir Augustus Franks of London, which numbers thousands. It is housed in the British Museum. The most important printed catalog of bookplates is the British Museum "Catalogue of the Franks Collection" in three volumes, 1903-04. The largest collection of bookplates in any English public library is in Liverpool: "over 60,000 specimens of the work of the finest engravers and etchers of all periods." The Catalogue of the Liverpool Collection has main entries arranged under the names of the owners of the plates, and index entries for styles, engravers and designers.

In America, the most notable depository is

President's Letter

THE FIFTY CLUB

Some far-seeing members of the medical profession of the State of Minnesota conceived an idea fifteen years ago of honoring, at the annual banquet of the Association, those physicians of the state who have practiced medicine for fifty years. Physicians who had practiced medicine for fifty years were accorded the privilege of becoming members of the Fifty Club. A group of forty-one physicians was the first so honored, in 1942. Since that year the annual ceremonies attendant upon admitting new members to the Fifty Club have taken place at the banquet of the Association. The ceremonies represent an expression of appreciation by the Association for fifty years of faithful and dedicated service to the sick, as well as to the medical profession, by physicians of this state. To date, certificates of membership in the Fifty Club have been issued to 319 men and women since the group was started. In addition to the original forty-one members, there were seven in 1943; nine in 1944; twelve in 1945; ten in 1946; twenty-four in 1947; eleven in 1948; fourteen in 1949; thirty-three in 1950; twenty in 1951; twenty-three in 1952; eighteen in 1953; twenty-two in 1954; eight in 1955; and twenty-four in 1956. In 1957 there were forty-three.

It is interesting to note that the number of physicians in the 1957 group was the largest to date, even larger than the number in the original 1942 group, which embraced a larger field. Of the forty-three honored in 1957, thirty-one were present at the banquet. Each received an honorary certificate and a lapel button. Among these was Dr. W. W. Will, a former president and long-time councilor of the Minnesota State Medical Association, who on that day celebrated not only his fifty years in practice, but his wedding anniversary and his birthday as well.

To those physicians eligible for the ceremonies of the Fifty Club but who are not able to attend them, the button and certificate are sent immediately after the meeting, except in those instances where the home community arranges a way of honoring these physicians. Thus, local ceremonies of honor were held in the case of Dr. O. W. Scholpp in Hutchinson, which is in Dr. C. G. Sheppard's district. The speaker of the House of Delegates is honored each year by the privilege of presenting the certificates and the lapel buttons.

For those concerned with the matter of early retirement, it is interesting to note that many of the physicians who received the coveted fifty-year award are still in the active practice of medicine, five and ten years later.

Among the women physicians in the group who practiced or who have practiced fifty years or longer are Orianna McDaniel of Minneapolis, 1944; Jeanette McLaren of Minneapolis, 1945 (deceased 1953); Anna Hurd of Minneapolis, 1950; Nellie Barsness of St. Paul, 1952; Stella Wilkinson of St. Paul, 1953 (deceased 1955); Hilda Luck of Mankato; Elizabeth Monahan of Minneapolis; and Margaret Smith, formerly of Minneapolis. Drs. Luck, Monahan and Smith became members of the Fifty Club in 1957.

Probably it would be difficult, and more than likely it would mean the listing of the names of all the physicians so honored, to write here about all who are well known in organized medicine. However, it is interesting to note that in the original group honored in 1942 was Dr. H. B. Sweetser, Sr., of Minneapolis, the father of the present president-elect of our Association, and Dr. P. E. Sheppard, of Hutchinson, the father of the present councilor of the Fourth District. Members of the

PRESIDENT'S LETTER

1943 group included Dr. George Haggard, of Minneapolis, who recently observed his 100th birthday and still keeps in touch with organized medicine and developments in medical research. The group also has included many officers of the Minnesota State Medical Association, among them Dr. W. H. Condit, who died last year and was treasurer of the Association for many years, and the late Dr. W. A. Coventry, of Duluth, a past president and long-time delegate to the American Medical Association. Both of these men became members of the Fifty Club in 1950. Dr. B. S. Adams, of Hibbing, a former president, joined the Club in 1951. Dr. W. F. Braasch, of Rochester, a former trustee of the American Medical Association, joined the Club in 1953. Dr. Robert M. Burns, of St. Paul, chairman of the Association's Radio and Television Committee for many years, joined the group in 1956. The same year, the late Dr. Ludwig L. Sogge, of Windom, who was so well known for his many years as chairman of the Public Policy Committee, became a member. Dr. E. A. Meyerding, former secretary of the Association, became a member in 1952. Dr. H. Z. Giffin, of Rochester, a former president, became a member in 1954. In addition, the following physicians, all former presidents, became members of the Fifty Club in the following years: Dr. J. T. Christison, St. Paul, 1942; Dr. William Davis, St. Paul, 1942; Dr. S. H. Boyer, Duluth, 1942; Dr. J. Frank Corbett, Minneapolis, 1947; Dr. S. H. Baxter, Minneapolis, 1952; Dr. G. D. Head, Minneapolis, 1947; Dr. E. M. Hammes, St. Paul, 1957; Dr. E. Mendelssohn Jones, St. Paul, 1957; Dr. F. J. Savage, St. Paul, 1951; W. L. Burnap, Fergus Falls, 1951; and Dr. E. L. Tuohy, formerly of Duluth, 1956.

It is obvious, from the letters received at the headquarters office, that physicians generally consider it a high honor to be included in this Fifty Club. This is well attested to by the letters received from those who are unable to attend. One telegram at the 1957 banquet, from one not able to attend, saluted the "gallant crew that has survived more than fifty years in the practice of medicine." Another of these physicians managed to attend the ceremonies on May 14 after much uncertainty, because she had been ministering to a patient who had been very ill for several days, and she did not know until shortly before the banquet that she would be able to leave him.

It is also of particular note that Dr. Justus Ohage, Sr., of St. Paul, was president of the Minnesota State Medical Association in 1895, and that his son, Dr. Justus Ohage, now of St. Paul, was president in 1954. Another outstanding combination of father and son concerns the Mayos. Dr. W. W. Mayo was president of the Association in 1873, and his sons, Dr. William J. Mayo and Dr. Charles H. Mayo, in 1894 and 1906, respectively.

It is truly an impressive honor and a notable experience to be able to complete fifty years in the service of mankind, to minister to the ills of the body, to soothe the restless spirits of many people, and to calm the disturbed emotions of many others. The practice of medicine is an honorable and noble profession. May it always be kept at this high level, and may people always have the opportunity to consult the physician of their own choice. May all physicians who are now practicing in Minnesota have the honor and privilege of pursuing their profession, so that one day they, too, may become members of the Fifty Club.

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is written in a cursive style with a large, sweeping loop at the beginning.

Committee on Medical Economics
Minnesota State Medical Association
George Earl, M.D., Chairman

ACTIVITY IN WASHINGTON SLOWS; NEW FISCAL YEAR BEGINS

Early in July federal legislative activity slowed, with limited action on the following matters of interest to physicians:

Jenkins-Keogh Legislation

Pressing ahead with its campaign for enactment at this session of the Jenkins-Keogh legislation, the American Thrift Assembly has written President Eisenhower asking him to have the Treasury Department re-examine its position and endorse the bill. Lucius S. Smith, III, Secretary of the A.T.A., signed the letter sent to the White House. In it he recalls that the President had supported this type of legislation in the 1952 campaign and he added "if this legislation (H. R. 9 and 10) now contains any vice, it has eluded several of the foremost tax experts in the nation. It is a fact that up to this time no member of the Ways and Means Committee or of the Treasury, or any government spokesman has voiced a single valid objection to the 1947 bill. Certainly 'loss of revenue' cannot in our judgment successfully now be argued against this proposal."

A total of twenty-seven professional and business organizations—medicine, law, pharmacy, dentistry, entertainment and small business—are urging the passage of this legislation.

The differences between this proposal and social security have been pointed out by co-author Representative Keogh. He said the difference between the two approaches was that "the social security program is intended to provide the minimum benefits necessary for a subsistence standard of living. The Jenkins-Keogh proposal is intended to provide a second layer of benefits for retirement or survivorship purposes that would complement social security benefits and would raise the living standard of the recipients above the subsistence level to one that more nearly approximates the standard of living attained by the recipient during the productive years.

"Another difference arises from the nature of the two programs. Social security is a form of compulsory social insurance that is provided by

law to guard against destitution and poverty in a person's declining years or under circumstances of dire adversity. Jenkins-Keogh is a tax opportunity to practice individual thrift and frugality according to a person's needs and inclinations."

Reminder on Social Security for War-time Service

You are reminded again that if you were on active duty as a physician in the military or naval forces of the United States during the World War II period (September 15, 1940, through July 2, 1947) or the post-World War II period (July 2, 1947, through December 31, 1956) you may be eligible for social security wage credits of \$160.00 for each month of this active duty, provided your discharge from the services was an honorable one. These wage credits may be granted to those who died in service as well as to those who died after discharge.

The World War II period and the post-World War II period are treated separately. However, if you have active military service after 1956, you will receive wage credits for any active service after 1950 and before 1957, even though you get retired pay from your service department based on that service.

Credits for military service between September 15, 1940, and January 1, 1957, count the same as wages in civilian employment. These credits, however, are not actually listed on your social security earnings record. You do not need to take any action on them until you make an application for retirement benefits. Proof of your military service will be needed when you apply for retirement payments or when an application is made for survivors' benefits in the event of your death. Be sure to preserve your military or naval service records.

Doctor Draft Act in Effect July 1

The House Armed Services Committee, chaired by Representative Carl Vinson (D., Ga.), drastically rewrote the doctor draft bill proposed by the Defense Department, slapped down an

appeal by the military to increase the ratio of physicians to troops and gave formal approval to the bill. It was enacted two days after the hearing started.

Defense department representatives had proposed an amendment that would apply to physicians up through age thirty-five if they had received an educational deferment. At the same time, the department had decided not to continue the national, state and local medical advisory committees to Selective Service, headed by Dr. Howard Rusk. Nor was the department interested in carrying over several provisions of the old law that had been written in to protect the rights of the physicians and dentists inducted under the act. The Committee, however, did continue the Rusk committees and the other protective devices that the Defense department's bill had intentionally omitted.

The AMA wanted the phrase "physicians, dentists and allied specialists" changed to read "other specialists" to bring all scientists under the act, but this idea was dropped.

As soon as the last witness had been heard, the committee immediately went to work on formal approval of the bill. And in less than ten minutes except for the formalities of House and Senate voting—a new law was made.

New Loans Available to Physicians and Dentists

The Small Business Administration is now making loans available to physicians, dentists, architects, lawyers and other professions. To qualify, applicants need only be in private practice, solo or group. This is a most unusual and sudden step for SBA which up to now has limited its aid to retail businesses and small industry. Just over a year ago, SBA extended loan eligibility to proprietary hospitals and nursing homes. The federal loan agency is not publicizing this new policy other than to notify regional offices to start taking applications from doctors needing funds to build or remodel offices, purchase equipment or for any other constructive purpose.

Research Overhead Costs High

Medical school deans recently made a strong effort at Senate hearings on health appropriations to get more federal help in paying the overhead cost of research. The schools now have so many

grants for specific research projects, said the deans, that they are going broke just paying the overhead—heat, lights, janitor service and administrative costs.

Some Increases in Health Appropriations

Acutely economy-conscious this year, Congress trimmed the Administration's requests for funds in every appropriations bill to be sent to Capitol Hill since January. Even the one-package bill carrying operating funds for the Labor Department and the Department of Health, Education and Welfare was reduced \$11 million in the over-all, but the total allowed for the National Institutes of Health—\$211 million—actually was \$21 million more than the White House asked for. Of this \$21 million increase, \$9.5 million goes into cancer; heart, arthritis and neurology receive \$2.5 million each, and \$4 million goes to mental health. Two-thirds of the cancer raise is earmarked for chemotherapy investigations. The National Heart Institute will devote nearly one-half of its \$2.5 million increase to a study on aging. To broaden and stress research in gastroenterology, \$500,000 in research grants money has been turned over to the National Institute of Arthritis and Metabolic Diseases for distribution.

Study Shows Need for New Chemicals Law

A recent AMA study shows a "patchwork" of state and federal laws regarding the labeling of hazardous chemicals and points up the need for a uniform law. A fall conference of interested parties in government, industry and medicine is planned to draft the model law which will then be submitted to legislative bodies. The proposed legislation is intended to reduce careless and ignorant handling of potentially harmful products in and around the home, in small businesses and in other areas where control of over exposure to chemicals is not as efficient as in the manufacturing process. The law will require informative labeling, including listing of possibly harmful ingredients, their potentialities for harm, directions for safe use and first-aid instructions. At present only 52 per cent of the states require labeling of caustics and 10 per cent of industrial chemicals, although all states require labeling of narcotics and 93 per cent of drugs.

TWO GOVERNMENT AGENCY REPORTS CONCERN COST OF MEDICAL CARE

Two reports from government agencies answer some of the questions on "how big are the bills that doctors and hospitals charge?"

One is the continuing survey of medical expenses by the Bureau of Labor Statistics as part of its task of reporting on the cost of living. The other is the schedule of fees paid by "medicare." All the fees and prices given on the charts are the amounts that are charged families with \$5,000 income or less.

The facts, as reported, show some of the following:

1. Charges of physicians have risen more rapidly in the last five years than the general cost of living. Physicians' fees went up 19 per cent while living costs rose 6 per cent. However, over a longer period, from 1936 to date, the cost of living has gone up 101 per cent while medical charges have risen 78 per cent.

2. Hospital charges have had a spectacular rise. Those charges are nearly four times what they were in 1936. They went up 39 per cent in the last five years and are expected to continue to rise by about 5 per cent a year.

3. Medical and dental care for the American people at this time is costing an estimated \$16 billion a year. More than \$5 out of each \$100 of family expenditures goes for medical bills. This amounts to about \$280 a year for the average family. Twenty years ago this same family in terms of dollars adjusted to take out cost-of-living advances, was spending \$123 a year, or less than 4 per cent of the total family budget, on medical items.

Physician's charges as outlined in a table reported by the Bureau of Labor Statistics indicate that on an average, a doctor treating a patient in his office will charge from \$3 to \$5 per visit assuming that there are no laboratory tests to be made and no special services performed. A doctor visiting a patient at home will charge in the neighborhood of \$4 to \$7.50.

Charges of specialists are not detailed in the government's studies and there was a wide range in what surgeons charge different patients.

The average net income of self-employed physicians was estimated at about \$15,150 this year. This is a rise from \$3,220 in 1937 and from \$11,191 in 1951. Gross earnings of physicians are

much larger but net earnings amount usually about 60 per cent of gross.

This trend toward higher medical costs has led to the growth of private health insurance. In 1911 the first big plan for prepayment of medical expenses appeared. By 1941, hospitalization insurance covered 12.3 million people, surgical insurance 5.4 million. Now, 116 million have hospitalization insurance, 101 million surgical coverage.

Congress is interested in a government approach to medical insurance. President Eisenhower has planned to ease antitrust regulations so insurance companies can pool their resources in order to write high-risk types of insurance. The object is to lower the cost so more people can be covered, especially older persons and those in isolated rural areas, and to increase the number of illnesses covered.

POSSIBLE BATTLE LOOMS OVER CONTROL OF CORPORATION

By early July a probable proxy fight was shaping up over control of the Schering Corporation, manufacturer of pharmaceuticals. Revlon, Inc. served notice that it had acquired some 8.5 per cent of Schering stock and intends to go in the drug business.

This is probably the largest single block of Schering stock (all of its management owns less than one per cent) but other large blocks are known to be held in brokers' names.

FIGURES ON LIFE EXPECTANCY

The chance of living to a ripe old age in this country varies to a degree, state by state, and varies a good deal more by sex. A recent statistical study shows that women in all parts of the country outlive men by six years. Men live longer in a cluster of six states in west north central U. S.—Minnesota, North Dakota, South Dakota, Nebraska, Iowa and Kansas. The shortest average life span turns up in the southwestern states—Arizona, Nevada and New Mexico.

Little consideration has been given, until very recently even the *possibility* that different forms of tuberculosis or different types of pulmonary tuberculosis, might be more satisfactorily treated by different drug regimens. On present evidence, it seems highly probable that the best management of tuberculosis will prove to be, not a single drug regimen which is optimal for all cases (it seems to have been the goal and the orientation of most investigations up to the present time), but that different regimens will be found to best suit different forms or types of the disease.—CARL MUSCHENHEIM, M.D. *American Review of Tuberculosis*, July, 1955.

American Medical Association

REPORT ON ACTIONS OF THE HOUSE OF DELEGATES

JUNE 3-7, 1957

Revision of the Principles of Medical Ethics, relations with the United Mine Workers of America Welfare and Retirement Fund, the federal government's Medicare program, new standards for medical schools, a new statement on occupational health programs and the issue of Social Security benefits for physicians were among the wide variety of subjects acted upon by the House of Delegates at the American Medical Association's 66th Annual Meeting held June 3-7 in New York City.

Dr. Gunnar Gundersen of La Crosse, Wis., member of the AMA Board of Trustees since 1948 and chairman for the past two years, was unanimously chosen president-elect for the year ahead. Dr. Gundersen, who also was first chairman of the Joint Commission on Accreditation of Hospitals from 1951 to 1953, will become president of the American Medical Association at the June, 1958, meeting in San Francisco. There he will succeed Dr. David B. Allman of Atlantic City, N. J., who became the 111th president at the Tuesday night inaugural ceremony in the Grand Ballroom of the Waldorf-Astoria Hotel.

The House of Delegates voted the 1957 Distinguished Service Award of the American Medical Association to Dr. Tom Douglas Spies, head of the department of nutrition and metabolism at Northwestern University Medical School, Chicago, and director of the nutrition clinic at Hillman Hospital, Birmingham, Alabama, for his outstanding contributions to the science of human nutrition. For only the third time in AMA history, the House also voted a special citation to a layman for outstanding service in advancing the ideals of medicine and contributing to the public welfare. Recipient of this award was Henry Viscardi, Jr., of West Hempstead, New York, founder and president of Abilities, Inc., which employs only severely disabled persons.

Physician registration at the New York meeting had already reached an all-time high at 5 p.m. Thursday with 18,982 counted and scores of registration cards still unprocessed. The previous high was chalked up at the 1953 New York meeting when the five-day total was 17,958 physicians.

New Principles of Medical Ethics

The House approved the long-discussed revision of the Principles of Medical Ethics, originally submitted at the 1956 annual meeting in Chicago. The final version, presented by the Council on Constitution and Bylaws and then amended by

reference committee and House discussions in New York, now reads as follows:

Preamble.—These principles are intended to aid physicians individually and collectively in maintaining a high level of ethical conduct. They are not laws but standards by which a physician may determine the propriety of his conduct in his relationship with patients, with colleagues, with members of allied professions, and with the public.

Section 1.—The principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion.

Section 2.—Physicians should strive continually to improve medical knowledge and skill, and should make available to their patients and colleagues the benefits of their professional attainments.

Section 3.—A physician should practice a method of healing founded on a scientific basis; and he should not voluntarily associate professionally with anyone who violates this principle.

Section 4.—The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed discipline. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.

Section 5.—A physician may choose whom he will serve. In an emergency, however, he should render service to the best of his ability. Having undertaken the care of a patient, he may not neglect him; and unless he has been discharged he may discontinue his services only after giving adequate notice. He should not solicit patients.

Section 6.—A physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care.

Section 7.—In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him, or under his supervision, to his patients. His fee should be commensurate with the services rendered and the patient's ability to pay. He should neither pay nor receive a commission for referral of patients. Drugs, remedies or appliances may be dispensed or supplied by the physician provided it is in the best interests of the patient.

Section 8.—A physician should seek consultation upon request; in doubtful or difficult cases; or whenever it appears that the quality of medical service may be enhanced thereby.

Section 9.—A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community.

Section 10.—The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community.

In approving the new Principles of Medical Ethics, the House of Delegates also reaffirmed the "Guides for Conduct for Physicians in Relationships with Institutions," adopted in 1951, and requested the Board of Trustees to devise and initiate a campaign to educate both physicians and the general public to the dangers inherent in the illegal corporate practice of medicine in its various forms.

Guides for Relations with UMWA Fund

In a key action on the basic issue of third-party intervention, as it affects the patient's free choice of physician and the physician's method of remuneration, the House adopted the "Suggested Guides to Relationships Between State and County Medical Societies and the United Mine Workers of America Welfare and Retirement Fund," which were submitted by the AMA Committee on Medical Care for Industrial Workers. In approving the guides, the House also recommended that the Board of Trustees study the feasibility and possibility of setting up similar guides for relations with other third-party groups such as management and labor union plans.

The statement, which outlines both medical society and UMWA responsibilities, contains these "General Guides":

1. All persons, including the beneficiaries of a third-party medical program such as the UMWA Fund, should have available to them good medical care and should be free to select their own physician from among those willing and able to render such service.
2. Free choice of physician and hospital by the patient should be preserved:
 - a. Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers.
 - b. A physician should accept only such terms or conditions for dispensing his services as will insure his free and complete exercise of independent medical judgment and skill, insure the quality of medical care, and avoid the exploitation of his services for financial profit.
 - c. The medical profession does not concede to a third party such as the UMWA Welfare and Retirement Fund in a medical care program the prerogative of passing judgment on the treatment rendered by physicians, including the necessity of hospitalization, length of stay, and the like.
3. A fee-for-service method of payment for physicians should be maintained except under unusual circumstances. These unusual circumstances shall be determined to exist only after a conference of the liaison committee and representatives of the Fund.
4. The qualifications of physicians to be on the hospital staff and membership on the hospital staff is to be determined solely by local hospital staffs and by local governing boards of hospitals.

The Medicare Program

The House considered three resolutions dealing with the federal government's Medicare program for the dependents of servicemen. The delegate adopted one resolution condemning any payment under the Medicare program "to or on behalf of any resident, fellow, intern or other house officer in similar status who is participating in a training program." Government sanction of such payments, the House declared, would give impetus to the improper corporate practice of medicine by hospitals or other nonmedical bodies. Such proposals, the House added, would violate traditional patterns of American medical practices, seriously aggravate problems of hospital-physician relationships, encourage charges by hospitals for residents' services to patients not under the Medicare program, and create a variety of additional problems in such areas as medical licensure and health insurance.

In another action on Medicare, the House recommended that the decision on type of contract and whether or not a fee schedule is included in future contract negotiations should be left to individual state determination. In this connection however, the House restated the AMA contention that: the Dependent Medical Care Act as enacted by Congress does not require fixed fee schedules; the establishment of such schedules would be more expensive than permitting physicians to charge their normal fees, and fixed fee schedules would ultimately disrupt the economics of medical practice.

The House also suggested that the AMA attempt to have existing Medicare regulations amended to incorporate the Association's policy that the practice of anesthesiology, pathology, radiology and physical medicine constitute the practice of medicine, and that fees for services by physicians in these specialties should be paid to the physician rendering the services.

New Statement on Medical Schools

To replace the "Essentials of an Acceptable Medical School," initially approved by the House of Delegates in 1910 and most recently revised in 1951, the House adopted a new statement entitled "Functions and Structure of a Modern Medical School." Presentation of the document followed a year of careful study by the Council on Medical Education and Hospitals in collaboration with the Association of American Medical Colleges.

The statement is intended to provide flexible guides which will "assist in attaining medical education of ever higher standards" and "serve as general but not specific criteria in the medical school accreditation program." The document encourages soundly conceived experimentation in medical education, and it discourages excessive concern with standardization.

"No rigid curriculum can be prescribed for ac-

completing the objectives of medical education," it states. "On the contrary, it is the responsibility of the faculty of each school continually to re-evaluate its curriculum and to provide in accordance with its own particular setting and in recognition of advances in science a sound and well-integrated educational program."

Occupational Health Programs

The House also approved a new statement on the "Scope, Objectives and Functions of Occupational Health Programs," submitted through the Board of Trustees by the Council on Industrial Health. The Board report to the House said: "The statement describes and defines orthodox in-plant medical programs as understood in this country today and distinguishes clearly between such programs and the various plans for comprehensive medical care of the sick. It should help to resolve misunderstandings concerning the specialty of occupational medicine."

In adopting the statement, the House agreed with a reference committee report which declared that "the House has before it a statement which for the first time clearly defines the scope, objectives and functions of occupational health programs. It marks the needs and boundaries of occupational medicine. It states in a positive fashion the proper place of occupational health programs in the practice of medicine and it clearly charts the pathways of communication between physicians in occupational health programs and physicians in the private practice of medicine."

Social Security for Doctors

Two resolutions favoring compulsory inclusion of physicians in the federal Social Security system and another one calling for a nationwide referendum of AMA members on the issue were rejected by the House. The delegates reaffirmed their opposition to compulsory coverage of physicians under the Old Age and Survivors Insurance provisions of the Social Security Act. They also recommended a strongly stepped-up informational program of education which will reach every member of the Association, explaining the reasons underlying the position of the House of Delegates on this issue. The House at the same time reaffirmed its support of the Jenkins-Keogh Bills.

Miscellaneous Actions

In considering sixty-six resolutions and many additional reports from the Board of Trustees, councils and committees, the House also:

Congratulated the Board and the Committee on Poliomyelitis for their prompt action in stimulating national interest in the polio immunization program;

Recommended further study and a progressive program of action, probably including legislative

changes, to solve the problem of narcotic addiction;

Urged a more careful screening of television and radio patent medicine advertisements;

Directed the Board of Trustees to investigate the indiscriminate use of stimulants such as amphetamine, particularly in relation to athletic programs;

Directed the Speaker to appoint a committee of five House members to study the Heller Report, a management survey of the Association's organizational mechanisms;

Commended the Law Department for its special report on professional liability and urged state and county medical societies to establish claims prevention programs and to show the new film, "The Doctor Defendant";

Opposed the establishment of any further veterans' facilities for the care of non-service-connected illnesses of veterans;

Condemned the compulsory assessment of medical men and staff members by hospitals in fund-raising campaigns;

Commended the television program, *Dr. Hudson's Secret Journal*, its producers and its star, Mr. John Howard, for an outstanding contribution to the public interest and welfare, and

Recommended payment of transportation expenses of Section Secretaries for AMA meetings which they are required to attend.

Opening Session

At the Monday opening session, Dr. Dwight Murray, retiring AMA president, stressed the triple theme of the personal touch in medicine, the necessity for freedom in medical practice, and the need for professional unity. Dr. Allman, then president-elect, warned against the dangers of third-party contractual agreements involving fixed fee schedules. The Goldberger Award in nutrition research was presented to Dr. Paul Gyorgy of Philadelphia. An AMA citation was awarded to the Parke-Davis & Company for its continuing series of institutional advertisements telling the story of medicine and medical progress. Dr. H. G. Weiskotten, who retired after many years as chairman of the Council on Medical Education and Hospitals, received two bound volumes of letters of appreciation and also an ovation from the House of Delegates.

Inaugural Ceremony

Dr. Allman, in his Tuesday night inaugural address, declared that the physician is constantly striving for a balance between personal, human values, scientific realities and the inevitabilities of God's will. The inaugural ceremony, which was telecast over Station WABD-TV in New York, included presentation of the Distinguished Service Award to Dr. Spies and the special layman's citation to Mr. Viscardi. Also taking part in the program was the United States Army Chorus of Washington, D. C.

Election of Officers

In addition to Dr. Gundersen, the new president-elect, the following officers were selected by the House on Thursday:

Dr. Jesse Hamer of Phoenix, Arizona, vice president; Dr. George F. Lull of Chicago, secretary; Dr. J. J. Moore of Chicago, treasurer; Dr. E. Vincent Askey of Los Angeles, speaker; and Dr. Louis Orr of Orlando, Florida, vice speaker.

Four new members were elected to the Board of Trustees: Dr. George Fister of Ogden, Utah, to succeed Dr. James R. Reuling; Dr. Cleon Nafe of Indianapolis, Indiana, to succeed Dr. James R. McVay; Dr. James Z. Appel of Lancaster, Pennsylvania, to replace the late Dr. Thomas P. Murdock; and Dr. Raymond McKeown of Coos Bay, Oregon, to replace Dr. Gundersen. Dr. Edwin S. Hamilton of Kankakee, Illinois, was elected chairman of the Board at its organization meeting after the elections in the House.

Dr. Homer L. Pearson, Jr., of Coral Gables, Florida, was renamed to the Judicial Council. Two new members were elected to the Council on Medical Education and Hospitals: Dr. Clark Wescoe of Lawrence, Kansas, to succeed Dr. Weiskotten, and Dr. Warde B. Allan of Baltimore, Maryland, to succeed Dr. F. D. Murphy of Lawrence, Kansas.

For the Council on Medical Service, Dr. Robert L. Novy of Detroit, Michigan, was re-elected, and Dr. Hoyt Woolley of Idaho Falls, Idaho, was chosen to replace Dr. McKeown. Dr. Warren W. Furey of Chicago was re-elected to the Council on Constitution and Bylaws.

At the Wednesday session of the House the Illinois State Medical Society made a record state society contribution to the American Medical Education Foundation by turning over \$170,450 to Dr. Louis H. Bauer of New York, foundation president.

NEW USE FOR GG

Gamma globulin injections appear to be a practical method for shortening the course of the skin disease, pityriasis rosea, provided they are given early enough, three University of Michigan researchers have reported. Among patients given gamma globulin during the first week of the eruption, the disease lasted an average of 17.3 days. The average untreated case required 31 days for the disease to run its course.—SALIN, R. W., CURTIS, A. C., and WHEELER, A., Ph.D.: Annual Meeting, AMA, New York City, June 7, 1957.

PREVENTION OF SECONDARY HEMORRHAGE IN TONSILLECTOMY

In an article on "Prevention of Secondary Hemorrhage in Tonsillectomy" published in the July 1957 issue of the *Eye, Ear, Nose and Throat Monthly*, the author discusses the causes and prevention of secondary post-tonsillectomy hemorrhage.

Secondary hemorrhage occurs up to the fourteenth day, but more frequently on the fifth and sixth day post-operatively. Predisposing factors and causes of secondary hemorrhage include infections, trauma, febrile diseases occurring during convalescence, dietary deficiencies, hypertension, blood dyscrasias and certain drugs.[†] A careful history and physical examination plus indicated laboratory procedures and specific preoperative and post-operative care will minimize most of these causes of secondary hemorrhage.

Since most cases of secondary hemorrhage occur when the septic membrane is sloughing, it would appear that such bleeding is due to the action of infection under the membrane lining of the tonsillar cavity. Steps to reduce the amount of infection, therefore, will reduce the incidence of hemorrhagic complications.

Recently, a medicated chewing gum has been developed containing the antibiotics, Neomycin sulfate and Gramicidin, plus a local anesthetic Propesin.* The combination of antibiotics offers a broad spectrum of antibacterial action with a low degree of sensitization, the anesthetic produces marked relief from pain, and the chewing motion elicited by the gum provides much desired exercise of the throat muscles.

Patients were divided into two groups: one week those operated upon received the medicated gum, the next week the medication was not given. Observations were continued until seventy patients had been seen in each group. Only one instance of secondary bleeding developed in the treated group, while some hemorrhage was encountered in 20 per cent of the untreated group. The tonsillar fossae of the patients receiving the drug were uniformly cleaner and free from excessive granulation tissue. The parents of the patients were less anxious, as malodorous breath, so frequently encountered in the untreated patients, was absent. The chewing gum afforded better distribution of the medication than lozenges, and the chewing motion caused earlier use of the jaw muscles. Postoperative pain, severe enough to elicit one or more phone calls from the parents for assistance, was decidedly decreased in the treated group. No cases of hypersensitivity were noted in the entire series.—RITTENHOUSE, E. A.: *E.E.N.&T. Monthly*, 36:406 (July) 1957.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The Northern Minnesota Medical Association will hold its annual meeting at Hibbing, Minnesota, Friday and Saturday, September 6 and 7, 1957.

The scientific program is as follows:

September 6

Morning Session - 10:00 A.M.

"Stevens-Johnson Syndrome"

DAVID SHER, M.D., Virginia

"The Early Detection and Treatment of Cancer of the Cervix"

DAVID DECKER, M.D., Rochester

"Life Saving Measures in the Severely Traumatized Patient"

JOSIAH FULLER, M.D., Duluth

"Disordered Action of the Heart as a Cause of Cardiac Failure"

RAYMOND D. PRUITT, M.D., Rochester

Afternoon Session - 2:00 P.M.

"The Vertebral Artery and its Relationship to Posterior Head Symptoms."

DONALD F. COBURN, M.D., Kansas City, Missouri

"Anti-Coagulation"

R. E. HANSON, M.D., Hibbing

"Perils and Hazards in Blood Transfusions"

VOLKER G. GOLDSCHMIDT, M.D., Duluth

Panel Discussion:

Moderator: WHITNEY WOODRUFF, M.D., Virginia

"The Patient with Cancer of the Breast"

(1) Surgical Aspects—Arnold J. Kremen, M.D., Minneapolis

(2) Radiological Aspects—Donn G. Mosser, M.D., Minneapolis

(3) Endocrine Aspects—Whitney Woodruff, M.D., Virginia

Evening Banquet

Speaker: Sigurd F. Olson, Ely
 Author of "The Singing Wilderness"
 Subject: "The Quetico-Superior Country"
 September 7

Morning Session - 9:00 A.M.

"Clinico-Roentgen-Pathological Conference"

Led by H. G. Moehring, M.D., Duluth

Adjournment - 12:00 Noon

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Southern Minnesota Medical Association will be held at The Terrace, Lake City, Minnesota, Monday, September 9, 1957. The following program has been scheduled.

Morning Session—9:00 A.M.

"The Problem of the Ruptured Diaphragm in the Injured Patient"

P. E. BERNATZ, M.D., Rochester

"The Advantages of Continuous Suction-drainage in the Management of a Variety of Surgical Wounds"

D. P. ANDERSON, M.D., Austin

"Clinical Significance of Prolapsed Gastric Mucosa"

DAVID DINES, M.D., Rochester

"Recurrent (18) Intestinal Hemorrhages due to Unrecognized Regional Enteritis"

P. W. BROWN, M.D., Rochester

Intermission

"The Results of Surgical Therapy for Angina Pectoris"

W. ROBERT SCHMIDT, M.D., Minneapolis

"Female Pseudohermaphroditism—The Adrenal Genital Syndrome"

E. J. RICHARDSON, M.D., St. Paul

"Treatment of Subarachnoid Hemorrhage"

ROSS H. MILLER, M.D., Rochester

"Cardiac Arrest with Cardiac Resuscitation—Case Report"

R. W. KEARNEY, M.D., Mankato

Luncheon and Business Meeting—12:00 M.

Afternoon Session—2:00 P.M.

"Criteria for Pediatric Psychiatry Referral"

MARY GIFFIN, M.D., Rochester

"Albers-Schönberg Disease (Marble Bone Disease)—Report of Case in One of Identical Twins"

J. T. OLIVE, M.D., Mankato

"Overuse of Steroid Therapy in Bronchial Asthma—Report of a Case"

G. A. PETERS, M.D., Rochester

"Management of Complications of Acute Nephritis in Childhood"

E. C. BURKE, M.D., Rochester

Intermission

"Left Sided Pneumatosis Coli—Case Report"

CHARLES NEUMEISTER, M.D., Minneapolis

"Constitutional Hepatic Dysfunction—An Unusual Cause of Jaundice in Childhood"

S. D. MILLS, M.D., Rochester

"Carcinoma of the Stomach Complicated by Pregnancy—Report of the Unusual Case"

ROBERT N. BOWERS, M.D., Lake City

Evening Session—6:30 P.M.

Banquet—The Terrace

"The French Regime on Lake Pepin"

DON MULDER, M.D., Rochester

MINNESOTA ACADEMY OF GENERAL PRACTICE

The Minnesota Academy of General Practice announces its seventh Annual Fall Refresher to be held at Hotel Leamington, October 15 and 16. The program, starting at 2 P.M. Tuesday, October 15, consists of ten hours of concentrated lectures by twenty-two outstanding medical teachers. Inquiries and reservation should be directed to the general chairman, John T. Pewters, M.D., 2020 1st Avenue So., Minneapolis.

SYMPOSIUM ON PERIPHERAL VASCULAR DISEASE

A Symposium on Peripheral Vascular Disease, sponsored by the Minnesota Heart Association and the Mayo Foundation, will be presented at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota, September 23, 24 and 25, 1957. Speakers will include the following:

September 23

Robert J. Boucek, Research Associate, Howard Hughes Medical Institute, Miami, Florida

Ivan Frantz, Jr., University of Minnesota Hospital, Minneapolis, Minnesota

Howard B. Burchell, Professor of Medicine, Mayo Foundation, Rochester, Minnesota

Francis J. Haddy, Veterans Administration Research Hospital, Chicago, Illinois

Charles A. Owen, Associate Professor of Clinical Pathology, Mayo Foundation, Rochester, Minnesota

Irvine H. Page, Cleveland Clinic, Research Division, Cleveland, Ohio

Maurice B. Visscher, Professor of Physiology, University of Minnesota, Minneapolis, Minnesota

G. E. Wakerlin, Professor of Physiology and Head of Department of Physiology, University of Illinois, Champaign-Urbana, Illinois

Jack P. Whisnant, Instructor in Neurology, Mayo Foundation, Rochester, Minnesota

J. Léo Wright, Fellow, American Heart Association

September 24

Edgar V. Allen, Senior Consultant in Medicine, Mayo Clinic; Professor of Medicine, Mayo Foundation, Rochester, Minnesota

Nelson W. Barker, Professor of Medicine, Mayo Foundation, Rochester, Minnesota

Edward D. Bayrd, Assistant Professor of Medicine, Mayo Foundation, Rochester, Minnesota

Frank H. Bethell, Director, University of Michigan Thomas Henry Simpson Memorial Institute for Medical Research, Ann Arbor, Michigan

Jesse E. Edwards, Professor of Pathology, Mayo Foundation, Rochester, Minnesota

J. Earle Estes, Assistant Professor of Medicine, Mayo Foundation, Rochester, Minnesota

John F. Fairbairn, Consultant in Medicine, Mayo Clinic, Rochester, Minnesota

Ray Wallace Gifford, Instructor in Medicine, Mayo Foundation, Rochester, Minnesota

Harold D. Green, Professor and Director, Department of Physiology and Pharmacology, Wake Forest College Bowman Gray School of Medicine, Winston-Salem, North Carolina

Edgar A. Hines, Jr., Professor of Medicine, Mayo Foundation, Rochester, Minnesota

John L. Juergens, Instructor in Medicine, Mayo Foundation, Rochester, Minnesota

Clark H. Millikan, Associate Professor of Neurology, Mayo Foundation, Rochester, Minnesota

Richard M. Shick, Assistant Professor of Medicine, Mayo Foundation, Rochester, Minnesota

MEETINGS AND ANNOUNCEMENTS

A. Spittel, Jr., Instructor in Medicine, Mayo Foundation, Rochester, Minnesota

September 25

Theron Clagett, Professor of Surgery, Mayo Foundation, Rochester, Minnesota

James W. Culbertson, Professor of Internal Medicine and Director of Cardiovascular Research Laboratories, State University of Iowa, Iowa City, Iowa

Henry Ellis, Jr., Assistant Professor of Surgery, Mayo Foundation, Rochester, Minnesota

Arshak S. Gurdjian, Professor of Neurosurgery, Wayne University, Detroit, Michigan

John C. Ivins, Assistant Professor of Orthopedic Surgery, Mayo Foundation, Rochester, Minnesota

Walter F. Kvale, Associate Professor of Medicine, Mayo Foundation, Rochester, Minnesota

John M. Manger, Former Fellow in Medicine, Mayo Foundation, Rochester, Minnesota

William S. MacCarty, Associate Professor of Neurosurgery, Mayo Foundation, Rochester, Minnesota

Wright C. McGoon, Consultant in Surgery, Mayo Clinic, Rochester, Minnesota

John H. Moyer, Chairman, Department of Internal Medicine, Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania

Harold M. Roth, Professor of Physiology, Mayo Foundation, Rochester, Minnesota

There is no registration fee. For information, reservations and information as to housing in Rochester, address Dr. Guy W. Daugherty, Chairman, Symposium Committee, 200 First Street Southwest, Rochester, Minnesota.

FELLOWSHIPS AVAILABLE FROM NATIONAL FOUNDATION FOR INFANTILE PARALYSIS

September 1 and December 1 are the current deadlines for applications to the National Foundation for Infantile Paralysis for post-doctoral fellowships in research, academic medicine or on the clinical field of psychiatry, rehabilitation, orthopedics, the management of poliomyelitis and preventive medicine. Financial support of the Fellow varies according to his previous education, his professional experience, marital status, and number of dependents. Compensation to the institution is arranged according to the program undertaken. For a full academic program, tuition and fees are allowed; for other programs, a sum not to exceed \$1,250.00 per year (includes tuition) is provided.

All awards are made upon recommendation of the appropriate National Foundation Fellowship Committee. U. S. citizenship is required, but those who have filed petition for naturalization will be considered. Partial fellowships are available for qualified veterans to supplement G.I. educational benefits. Applications must be received by September 1 for consideration in November, by December 1 for consideration in February, and by March 1 for consideration in May.

Postdoctoral Training in Research or Academic Medicine.—Awarded to applicants with an M.D., Ph.D., or equivalent degree for basic or advanced training in laboratory research in medicine and the related biologic and physical sciences. This program is *not* intended for experienced investigators who need support for a research project. Financial benefits, in addition to the

compensation to the institution, vary from \$3,600 to \$6,000 a year. Under unusual circumstances, higher stipends may be permitted. Transportation not to exceed \$600 may be paid if foreign study is approved.

Postdoctoral Study in the Clinical Fields:

1. **Rehabilitation.**—For licensed physicians interested in rehabilitation as it relates to their specialty and who wish to study the concept and basic techniques of rehabilitation. One year of internship is required and license to practice in the United States. For residents who wish specialty training in Physical Medicine and Rehabilitation, awards are made for a period of one, two, or three years, depending upon the time required to complete eligibility requirements for certification by the American Board of Physical Medicine and Rehabilitation. Preference is given to applicants under forty years of age. Financial benefits, in addition to compensation to the institution, are \$300 or \$350 per month depending on marital status, with \$25 additional for each dependent child.

2. **Psychiatry.**—For licensed physicians who have had two years of graduate training in psychiatry acceptable to the American Board of Psychiatry and Neurology, and who are interested in the emotional problems of patients with physical disabilities. The program of study is to be undertaken in a setting where medical and associated medical personnel are engaged co-operatively in a program of comprehensive patient care. Interest in research and teaching are highly desirable. Awards are made for a period of one year and are subject to renewal. Financial benefits, in addition to the compensation to the institution, vary from \$3,600 to \$6,000 a year. Under unusual circumstances, higher stipends may be permitted.

3. **Orthopedics.**—For surgeons who have completed requirements for certification by the American Board of Orthopedic Surgery (or who have had equivalent training) and who are interested in advanced study in orthopedics in preparation for teaching or research. The age limit is thirty-six. Awards are made for a period of one year and are subject to renewal. Financial benefits, in addition to the compensation to the institution, vary from \$4,500 to \$6,000. Under unusual circumstances, higher stipends may be permitted.

4. **The Management of Poliomyelitis.**—For licensed physicians who wish to acquire a knowledge of the various aspects of the total care of poliomyelitis patients. A fellowship for one year for full time study may be undertaken at any institution having suitable facilities and staff for this type of program. One year of internship is required. Financial benefits are \$300 or \$350 per month depending on marital status, with \$25 additional for each dependent child. Compensation to the institution is also arranged.

5. **Preventive Medicine.**—For physicians who desire to prepare for the teaching of preventive medicine. Applicants must have had two years of training and experience, including responsibility for teaching, in one of the areas related to preventive medicine. Awards are

made for a period of one year and are subject to renewal. Financial benefits, in addition to the compensation to the institution, vary from \$4,500 to \$6,000 a year. Under unusual circumstances, higher stipends may be permitted.

Short Courses in the Care of the Poliomyelitis Patient.—Fellowships are offered to doctors, nurses, physical therapists and occupational therapists to attend short courses (one week to three months) in the care of the poliomyelitis patient. A list of institutions offering such courses will be sent on request. Maintenance, transportation and tuition if required, will be paid. Applicants will be expected to attend the course nearest their place of residence if the course is of less than three months' duration. Doctors and nurses should apply to their local chapters of the National Foundation. Physical therapists and occupational therapists should apply to the Division of Professional Education of the National Foundation. Applications must be filed at least six weeks before the course begins.

For further information write to: Division of Professional Education, National Foundation for Infantile Paralysis, 301 East 42nd Street, New York 17, New York.

NEW LAW ON EMERGENCY ADMISSIONS TO STATE MENTAL HOSPITALS

The 1957 Minnesota legislative session passed an act relating to the emergency admissions of patients to state mental hospitals. This act is Chapter 70, Laws of 1957, and became effective March 5, 1957.

The amendment provides that a patient may be admitted as an emergency to a state mental hospital upon written certification by a physician that the patient is mentally ill and is likely to harm himself or others. The hospital superintendent must give consent to the admission. The purpose of the amendment is to avoid holding a mentally-ill person in jail in the rare instance when the probate judge is out of town or unavailable for some other reason. It is anticipated that this procedure will be used in only the most unusual cases and then as a temporary measure, for the certification can be effected for only a seventy-two-hour period. Prior to expiration of this three-day period, if so indicated, the probate court is petitioned for the usual commitment.

Certification forms have been prepared and may be obtained at the state mental hospitals or at the county welfare offices.

ESSAY CONTEST

Prizes for the 1958 essay contest sponsored by the Association of American Physicians and Surgeons Freedom Programs, Inc., have been announced. There will be a \$1,000 first prize, a \$500 second prize, and a \$250 third prize. In addition there will be four prizes of \$100 each and seven prizes of \$75 each. Certificates of "meritorious achievement" are awarded to all contestants whose essays reach the national finals.

This contest, which the Minnesota State Medical Association voted to co-sponsor at its recent annual meet-

ing, is open to high school students, and the choice of topics includes "The Advantages of Private Medical Care" and "The Advantages of the American Free Enterprise System." A Minnesota girl, Sonia Gustavs of Olivia, won the 1957 national contest. She was sponsored by the Renville-Redwood County Medical Society.

PATHOLOGISTS MEET

The annual spring meeting and seminar of the Minnesota Society of Clinical Pathologists was held at St. Joseph's Hospital, St. Paul, on May 14, 1957. The regular all-day tumor seminar was moderated by Dr. William A. Meissner of Boston who is associate professor of pathology at Harvard Medical School and pathologist at the New England Baptist and Palm Memorial Hospitals, Boston.

The eleventh annual Arthur H. Sanford Lecture sponsored by the Minnesota Society of Clinical Pathologists, was given by Dr. Arthur T. Hertig of Boston who is the Shattuck professor of pathology at Harvard Medical School. This lecture was given before a general session of the Minnesota State Medical Association, and its title was "Essentials of Endometrial Pathology."

A dinner and business meeting were held at which the following officers were elected: President: Dr. Lyman A. Weed, Rochester; Vice-president, Dr. Harold F. Joffe, Virginia; local councilor, Dr. Arthur C. Auderheide, Duluth. Officers who were held over from previous terms were two local councilors, Dr. Frederic H. Lott, Minneapolis, Dr. Malcolm B. Dockerty, Rochester, and the secretary-treasurer and ASCP councilor Dr. George G. Stilwell, Rochester.

UNIVERSITY COURSE ON ADVANCED ORAL PATHOLOGY

The Medical and Dental Faculties of the University of Minnesota will present a course in "Advanced Oral Pathology" during the week of April 28 through May 2, 1958. Both lectures and pathologic slide study will be included. The subjects covered will be: neoplastic and non-neoplastic diseases of the salivary glands, neoplasms of dental origin, bone pathology, soft tissue neoplasms, dermatologic pathology, diseases of the lymphoid system, and oral roentgenographic evidences of systemic disease.

The faculty will include Dr. Robert Lukes, Armed Forces Institute of Pathology; Drs. D. C. Dahlin and Edward Stafne of the Mayo Clinic; Dr. Robert Goltz of the Medical School, University of Minnesota; and Drs. Anand Chaudhry and Robert J. Gorlin of the School of Dentistry, University of Minnesota.

The tuition fee will be \$50, and an additional \$50 will be charged if room and board at the Center for Continuation Studies are desired. Further information may be obtained from Dr. Robert J. Gorlin, Chairman, Division of Oral Pathology, School of Dentistry, University of Minnesota, Minneapolis, Minnesota.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, this fall are:

- September 24-26
Pediatrics for Specialists
- October 7-9
Obstetrics for General Physicians
- October 24-26
Symposium on Skin Cancer for Specialists

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

FILMS AVAILABLE FOR MEDICAL GROUPS

"Monganga," the outstanding "March of Medicine" television presentation, produced by the Smith, Kline and French Laboratories in co-operation with the AMA, has been made available to medical groups before release to the general public. It is a full color, 16 mm. sound film which describes the work of Dr. John Ross, a medical missionary in the Belgian Congo. Information about the film and reservations for showing dates may be secured from the Film Center, Smith, Kline and French Laboratories, 1530 Spring Garden Street, Philadelphia 1, Pennsylvania.

The Upjohn Company now has a limited number of 16 mm. sound kinescopes (films) of their fifth Grand Rounds closed-circuit television program, "Diagnostic and Therapeutic Advances in Liver Disease." Showing time is ninety minutes. This film, as well as films of the first four Grand Rounds ("Acute Abdominal Problems," "The Cardiac Patient in Stress," "Borderlines of Cancer," and "Pre-Malignant and Malignant Lesions of the Breast and Colon") are available without charge for showing before any group in the Medical or allied professions. To make arrangements for a local showing, contact your local Upjohn representative, your nearest Upjohn branch office, or R. P. Trubey, head of the professional advertising department, The Upjohn Company, Kalamazoo, Michigan.

The second film in the AMA-American Bar Association series on "Medicine and the Law" deals with prevention of professional liability action. Titled "The Doctor Defendant," the film is available from the AMA Film Library for medical society showings. It is a companion to "The Medical Witness" in the series produced by the William S. Merrell Company in co-operation with the AMA and ABA.

LABORATORY ASSISTANTS GRADUATE IN SEPTEMBER

Upon satisfactory completion of the course for laboratory assistants of the general extension division of the University of Minnesota, twenty students will receive certificates on September 28. The students are trained to do hemoglobin determinations, white blood cell counts, red blood cell counts, normal differential smears and

recognition of an abnormal smear, routine urinalysis, titration of gastric acidity, BMR tests, blood group typing and limited blood chemistry determinations (sugar, urea nitrogen, chloride). The students are best qualified to work in physician's office or to assist a registered medical technologist (M.T., ASCP) in a hospital or clinical laboratory. Information about the students and the training program may be obtained from Verna Rausch, assistant professor of medical technology, C205 Mayo Building, University of Minnesota, Minneapolis 14, Minnesota.

PRESERVATION OF BOOKPLATES

(Continued from Page 585)

probably the building of the American Antiquarian Society of Worcester, Massachusetts. This Society's collection was begun with the gift of the private collection of Rev. Herbert E. Lombard, numbering 40,000, in 1934. At that time he wrote in the Year Book of the American Society of Bookplate Collectors and Designers, "It is strongest in early American plates, though practically (and in many cases entirely) complete in E.D.F., J.W.S., S.L.S., A.N.M., W.F.H., T.C. and other artists." By these initials he referred to Edwin Davis French of Saranac Lake, America's best known designer and engraver of the modern bookplate; J. Winfred Spenceley, contemporary of French, etcher and engraver; Sidney L. Smith of Boston; A. N. Macdonald; William F. Hopson, engraver of New Haven, and Timothy Cole, engraver on wood; all of whom won international recognition.

The Print Department, Metropolitan Museum of Art, New York City, is a famous depository. The William E. Baillie Collection of more than 20,000 items came to the museum in 1920. The Print Room is open week days from 10 to 4:45, except Saturday, when it is open from 10 to 1:00. It is closed on Sunday.

Woman's Auxiliary

WOMAN'S AUXILIARY TO AMA HOLDS 34TH ANNUAL CONVENTION

The 34th annual convention of the Woman's Auxiliary to the American Medical Association was held in New York concurrently with the 106th annual meeting of the AMA, June 3-7, at the Roosevelt Hotel.

Registered as delegates from Minnesota were Mrs. Karl Anderson, Minneapolis; Mrs. H. E. Bakkila, Duluth; Mrs. George Earl, St. Paul; Mrs. Reuben Erickson, Minneapolis; Mrs. L. P. Howell, Rochester; Mrs. A. J. Lenarz, Browerville; Mrs. J. P. Medelman, St. Paul; Mrs. C. L. Oppgaard, Crookston; Mrs. C. L. Sheedy, Austin; Mrs. William F. Skaife, Little Falls; Mrs. George Snyder, St. Paul, and Mrs. H. B. Sweetser, Minneapolis. We were allowed twenty-three delegates, but as few of the other delegations were complete, we did not feel that this was a bad representation.

On Monday, June 3, there were concurrent round table discussions on legislation, public relations, program, organization, *Today's Health*, the American Medical Education Foundation, publications, newsletters and *Bulletin*. We recessed in time to attend the complimentary tea at the Tavern-on-the-Green in Central Park. This tea, which was given by one of the pharmaceutical firms, honored Mrs. Robert Flanders, the national president, and Mrs. Paul Craig, president-elect.

The convention opened formally on Tuesday, June 4, at 8:45 a.m. with the usual formalities: invocation, pledge of allegiance to the flag, the Auxiliary pledge of loyalty, greetings from the president of the New York County Medical Society and the general convention chairman. The address of welcome was given by the immediate past president of the Woman's Auxiliary to the State Medical Society of New York and the response by the president of the Woman's Auxiliary to the Utah State Medical Association.

Mrs. Flanders introduced the Auxiliary convention chairmen: Mrs. Harry Pohlmann and Mrs. E. V. B. Vurgason, and the president-elect, Mrs. Craig.

After the memorial service honoring our eleven Auxiliary members as well as those from every state who had died during the past year, Mrs. Flanders gave her address in which she said that she had never felt that her cause was not the right one nor that she was walking alone. She thanked all for giving her the opportunity for service.

Reports of the state presidents on Wednesday and Thursday showed increased activity in all the states on the priority projects of AMEF, *Today's Health* and increasing activity also in the field of legislation and the various phases of AMA activity. Minnesota is one of the few states that has started working with the auxiliary to the student AMA, and in various phases of safety and mental health.

One of the highlights of the conference was the address of Dr. Howard Rusk, professor and chairman of

the Department of Physical Medicine and Rehabilitation at Bellevue Medical Center, New York University. His topic was "Sick People in a Troubled World," and in a very refreshing manner he warned us that, as our husbands had added years to the life span, it was part of our responsibility to add life to those years. He called our attention to the tools of rehabilitation and felt that we had a difficult and important role to play in trying to build a cornerstone in human understanding. In his travels in foreign countries he felt that our rehabilitation of handicapped people was accomplishing more goodwill than some of our other expenditures.

Wednesday sessions continued with reports of national chairmen and reports of the election committee of the 1958 nominating committee.

At the luncheon honoring Mrs. Flanders and Mrs. Craig, Dr. Allman and Dr. Murray spoke, and the trustees and officers of the AMA were honored guests. Mrs. Flanders presented Dr. George Lull with a check for \$113,518.77 for AMEF.

Thursday's meeting was an anticlimax as far as excitement was concerned.

The election of the slate presented by the nominating committee was accepted. Mrs. E. Arthur Underwood, Vancouver, Washington, is president-elect. It was decided to incorporate the Auxiliary on the advice of the AMA legal staff so, until that is worked out, no amendments should be passed.

Mrs. Craig was installed as president of the Auxiliary and delivered her masterful address entitled "Health: A Joint Endeavor," which will be printed verbatim in the fall issue of *Bulletin*. She stressed that a changing world brings changing problems of sudden death, multiple injuries and problems of rehabilitation; it also brings new age patterns, more older citizens and new neighborhood patterns. There is urgent need to keep emotional health in a technologically difficult world. Mrs. Craig also said that there is now new meaning in the art of living together with minds and hearts sensitive to the relationships between people. There is increasing significance and importance in high moral values. This is the frontier on which we can pioneer improving working knowledge of human relations and group behavior. We must simplify and streamline our organization and develop ideas.

The national projects to be given priority are AMEF and *Today's Health*. We should also stress greater understanding of Auxiliary fundamentals, the AMA and human relations and group behavior.

At her post-convention board meeting, Mrs. Craig attempted to set the pitch for the fall conference for Presidents and Presidents-elect which will be a "how-to-do-it" conference with the emphasis on group relationships. She stressed that we must remember these basic concepts:

- . We are a working community service group rather than just a meeting type of organization.
- . We can do our most productive work under the direct guidance of the medical society.
- . We should continuously evaluate our projects to help us judge whether we are carrying out our objectives.
- . We will want to utilize methods to suit changing times and the best resources from the educational field.
- . We must develop our activities to give motivation and a sense of participation and achievement to the individual member. With these ideas to guide us, Mrs. Cig hoped that we may better learn how to assist in programs for the advancement of medicine and public health and to promote mutual understanding among physicians' families—the objectives which bring us together and upon which all of our work is based.

MRS. C. L. OPPEGAARD, *President*

MINNESOTA AUXILIARY CHAIRMEN APPOINTED

State committee chairmen for the 1957-58 year include:

- Medical Careers.....
Mrs. S. M. Loken, St. Paul (Nursing)
Mrs. E. H. Soule, Rochester (Other careers)
- M.E.F.....Mrs. M. D. Starekow, Thief River Falls
- Archives.....Mrs. James L. Benepe, St. Paul
- Bulletin.....Mrs. A. W. Diessner, Redwood Falls
- Cancer.....Mrs. W. O. Finkelnburg, Winona
- Civil Defense.....Mrs. Vernon Sommerdorf, St. Paul
Mrs. Leo A. Nash, St. Paul
- Finance.....Mrs. Charles Froats, St. Paul
- Physician Doctor's Wife.....Mrs. C. E. Carlson, Alexandria
- Health Days and Health Education.....
Mrs. Conrad Karleen, Minneapolis
- Memorial.....Mrs. Howard Satterlee, Lewiston
- Legislation.....Mrs. L. Raymond Scherer, Minneapolis
- Magazines for Friendship.....
Mrs. L. J. Leonard, Minneapolis
- Medical and Surgical Relief.....
Mrs. Clarence Jacobson, Chisholm
Mrs. Warren Wilson, Northfield
- Mental Health.....Mrs. William Gjerde, Lake City
- Minnesota Medicine.....Mrs. A. B. Rosenfield, Minneapolis
- Organization.....Mrs. Reuben Erickson, Minneapolis
- Press and Publicity.....Mrs. Harold Ulvestad, Minneapolis
- Printing and Roster.....Mrs. L. R. Boies, Hopkins
- Program Co-ordinator.....
Mrs. Harold Benjamin, Minneapolis
- Public Relations.....Mrs. M. O. Wallace, Duluth
- Resolutions.....Mrs. A. J. Lenarz, Brownville
- Revisions.....Mrs. Harold Wahlquist, Minneapolis
- Safety.....Mrs. Ralph L. Olson, St. Paul
- Social.....Mrs. Robert Priest, Minneapolis
Mrs. E. T. Evans, Minneapolis
Mrs. John Meade, St. Paul
Mrs. Wallace Gleason, St. Paul
Mrs. E. E. Barrett, Duluth
Mrs. R. E. Davis, Waseca
- Today's Health.....Mrs. H. P. VanCleve, Austin

HEADACHES MAY BE SYMPTOM OF MORE SERIOUS DISORDERS

Headaches, often rated man's most common and annoying complaint, may be either important or unimportant from a medical standpoint. However, a bulletin from the Minnesota State Medical Association warns that the person who indulges in prolonged self-medication for persistent, severe headaches may be in for some serious illness if he does not seek professional help.

Fortunately, the ordinary headache ends within twenty-four hours but when it is more severe and the causes obscure, extensive medical measures may be required. The migraine is a severe headache usually starting on one side of the head with additional varied and individual symptoms. Many migraine victims could attain comfort if they tried to correct faulty modes of living and eliminate undesirable environmental factors.

Women are especially subject to headaches for a number of reasons; menstrual difficulties, for one. For this cause, the doctor can prescribe drugs which give a great deal of relief but they must be used with understanding and discretion.

Pregnant women are also subject to difficulties which may first be detected by severe headaches; one of the first symptoms of toxemia, for example, is blurred vision accompanied by headaches.

For both men and women, the middle-age years mean a time when the activity of the sex glands declines; in both sexes there may be frequent annoying headaches at this time of life.

Headaches have even been known to be caused by "caffeine withdrawal." For many individuals, coffee produces a sense of well-being and going without it for a time can cause frequent headaches.

Occupational diseases may also cause headaches. Toxic industrial hazards including gases, dusts, vapors, smoke, fumes, liquids, chemical agents and explosive mixtures may be contributing factors to headaches, dizziness and visual disturbances.

Among the more serious causes of headaches are strokes and arteriosclerosis or hardening of the arteries.

Of course, adequate treatment of a complaint in or about the head depends on a correct diagnosis of the cause. Anyone who suffers from chronic head pain should put himself under the care of a competent physician as soon as possible.

BACKACHES POSE DIFFICULT DIAGNOSTIC PROBLEM

A person may have congenital defects in his back, and even structural changes, but still not have clinical symptoms, according to a report by Drs. Tom M. Fullenlove and A. Justin Williams, of San Francisco, in an article on x-ray studies in pre-employment physical examinations published in the April, 1957, issue of *Radiology*.

Conclusions advanced by the two San Francisco physicians were based on a study of 200 persons without any backaches as compared with another 200 persons who had suffered from the complaint. However, in each of the two groups there was just about an equal distribution of both congenital defects and structural changes.

Other conclusions from their study:

—Congenital defects or anatomical variations are not independently a cause of backache.

—A great many backaches may be the result of soft tissue changes, which are not seen on a plain x-ray film. These changes would include strains, sprains and inflammations.

In Memoriam

FRANK E. BURCH

Dr. Frank E. Burch, nationally-known St. Paul ophthalmologist, died June 30, 1957, at his summer home near Two Harbors, Minnesota. He was eighty-nine years old.

Born in Menomonie, Wisconsin, Dr. Burch graduated from the University of Minnesota Medical School in 1897. He interned at St. Luke's Hospital, St. Paul, and took postgraduate work at Johns Hopkins University, Baltimore, at the Royal London Ophthalmic College and at the University of Vienna. He entered general practice at Glencoe, Minnesota, and remained there for two years. In 1904 he moved to St. Paul and remained in active practice there until he retired in 1946.

Dr. Burch was professor and chief of the department of ophthalmology at the University of Minnesota as well as ophthalmologist for the University Hospitals and Miller Hospital, St. Paul. He was a past president of the American Academy of Ophthalmology and Otolaryngology, secretary of the Minnesota Society for the Prevention of Blindness and a member of the advisory committee of the National Society for the Prevention of Blindness. In 1940 he spent four months in Peiping, China, as visiting professor of Peiping Union Medical College under the auspices of the Rockefeller Foundation.

He was a past president of the Ramsey County Medical Society, the Minnesota Academy of Medicine, the Minnesota Academy of Ophthalmology and an active member of the American Ophthalmological Society, the Minnesota State Medical Association and the American Medical Association. In 1937 he was the United States Delegate to the International Congress of Ophthalmology held in Cairo, Egypt.

Dr. Burch is survived by his son, Dr. Edward P. Burch, St. Paul; a daughter, Mrs. Glen S. Taylor, Palo Alto, California, and three grandchildren.

DETLOF E. JOHNSON

Dr. Detlof E. Johnson, South St. Paul physician, died June 30, 1957. He was fifty-five years old.

A native of Stillwater, Minnesota, Dr. Johnson attended Macalester College, St. Paul, and graduated from the University of Minnesota Medical School. He served his internship at Ancker Hospital, St. Paul.

Dr. Johnson practiced medicine in Duluth for a number of years as well as in St. Paul and South St. Paul. He was on the staff of St. John's Hospital, St. Paul, and a former member of the St. Louis County Medical Society, the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Alice, and two daughters, Mrs. Ronald Jorgenson, Fargo, North Dakota, and Carolyn, South St. Paul.

JOHN VINCENT KELLY

Dr. John V. Kelly, a practicing physician in St. Paul for forty-five years, died June 20, 1957. He was seventy-four years old.

He had retired from active practice last January and was the last survivor of three brothers who were physicians in St. Paul.

Dr. Kelly was born in St. Paul, attended Cret High School and the University of Minnesota. He graduated from Marquette University in 1911 and began to practice in St. Paul the same year.

He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association, the American Medical Association and was a staff member of St. Joseph's and St. Luke's Hospitals, St. Paul.

Survivors include his wife, Agnes; four daughters: Mrs. C. E. deRosier, Mrs. James E. Budge, Mrs. Eugene Daugherty, and Mrs. Russell Jensen, all of St. Paul; two sons: Dr. Edward H. Kelly, St. Paul, and Major John V. Kelly, Jr., Riverside, California, and one sister, Miss Margaret Kelly, St. Paul. There are twenty-one grandchildren.

GEORGE F. REINEKE

Dr. George F. Reineke, a resident of New Ulm, Minnesota, for over fifty years, died at his home May 21, 1957. He was eighty-six years old.

Dr. Reineke was born in Waseca county, graduated from the University of Minnesota Medical School in 1896 and settled in New Ulm immediately after graduation. In 1903 he went to Vienna for a postgraduate course in diseases of the eye, ear, nose and throat. He retired from active practice several years ago after maintaining an office in the Fritsche block for many years. He was a member of the Brown County Medical Society, the Minnesota State Medical Association, the American Medical Association and the American Academy of Ophthalmology and Otolaryngology.

In addition, he was active in civic affairs in New Ulm for many years; he served as Brown county coroner from 1910 to 1951 and was a member of the New Ulm school board from 1904 to 1919. He was New Ulm health officer from 1900 to 1903 and an active member of the Methodist church, serving as lay minister and as trustee from 1918 to 1935.

A director of the New Ulm Savings and Loan Association, he served as president of the Association for thirty-five years. He was a member of the Charity Lodge, A. F. & A. M., New Ulm chapter, R. A. M., DeMolay Commandery, a past patron of the Orient Chapter, O.E.S., and Zuhrah Temple, Minneapolis.

Survivors include his wife, Anna; a son, Dr. Harold G. Reineke, Cincinnati, Ohio; a daughter, Mrs. Palmer Swenson, Dawson, Minnesota; and four brothers: Louis, Waseca, Minnesota; the Rev. Ernest, Lake City, Minnesota.

EFFECTIVE, DEPENDABLE THERAPY FOR VAGINITIS

*"...results for
trichomoniasis
have been best
and more
consistent¹
using
Floraquin..."*

Floraquin[®] eliminates trichomonal and mycotic infection; restores normal vaginal acidity

Leukorrhea is by far the most frequent symptom of vaginitis; trichomonads and monilia are the most common causes. Many authors have reported² trichomonal protozoa in the vagina of 25 per cent of obstetric and gynecologic patients. Increased use of broad spectrum antibiotics has resulted in a sharp rise in the incidence of monilial infections.

Floraquin effectively eradicates both trichomonal and monilial vaginal infections through the action of its Diodoquin[®] content. Floraquin also furnishes boric acid and sugar to restore the normal vaginal acidity which inhibits patho-

gens and favors the growth of protective Döderlein bacilli.

Pitt¹ recommends vaginal insufflation of Floraquin powder daily for three to five days, followed by acid douches and the daily insertion of Floraquin vaginal tablets throughout one or two menstrual cycles. G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

nesota; Albert, San Antonio, Texas; and Rudolph, August, Missouri and one sister, Mrs. Clifford Thompson, Faribault, Minnesota.

EDWARD D. RISSE

Dr. Edward D. Risser, former Winona, Minnesota, physician, died at his home in Pasadena, California, May 1, 1957. He was sixty-six years old.

Dr. Risser, an eye, ear, nose and throat specialist, practiced in Winona from 1921 to 1943 when he moved to California. He was born in Des Moines, Iowa, and received his medical education at the University of Iowa.

Dr. Risser had been a member of the Winona County Medical Society and the Minnesota State Medical Association. He also belonged to the Los Angeles County Medical Association, the California Medical Association, the American Medical Association, the Pacific Coast Oto-Ophthalmological Society and the American Academy of Ophthalmology and Otolaryngology. He served on the staffs of St. Luke's, Huntington Memorial and Alta Vista Hospitals, all in Pasadena.

Other memberships included the Pasadena Consistory of the Masonic order, the University Club of Pasadena and the First Methodist Church. In Winona he was a member of Central Methodist Church and Winona Lodge 18, A.F.&A.M.

Dr. Risser is survived by his wife, Mona; three daughters: Mrs. Walter J. Vernon, National City, California; Mrs. George R. Atkins, Oakland, California, and Mrs. H. James Christian, Danville, California; one son, Edwin J., Berkeley, California; two brothers: Dr. Joseph C. and J. Raymond, Pasadena; one sister, Katherine, Pasadena, and eight grandchildren.

FRANCIS J. SCHATZ

Dr. Francis J. Schatz, prominent St. Cloud, Minnesota, physician for more than thirty-six years, died May 28, 1957. He was seventy-four years old.

Dr. Schatz, by his own count, had delivered more than 9,500 babies in his lifetime. Before moving to St. Cloud in 1921 he practiced in Turtle Lake, Wisconsin; Rosemount, Minnesota; and South St. Paul. He was born in Montgomery, Minnesota, graduated from St. Thomas College, St. Paul, and from Jefferson Medical School, Philadelphia.

Dr. Schatz was elevated to the Order of the Knights of St. Gregory the Great by Pope Pius XII in Rome in 1952.

He was a member of the Stearns-Benton County Medical Society, the Minnesota State Medical Association, the American Medical Association, the American College of Obstetrics and Gynecology of which he was a founder, the American Committee of Maternal Welfare, the Catholic Physicians Guild, and the American Academy of General Practice.

Dr. Schatz also belonged to American Legion Post 76. He was chief of obstetrics at the St. Cloud hospital for many years.

His survivors include five daughters: Mrs. J. P. O'Keefe, St. Cloud; Mrs. Loretta McNeil, Mountain

View, California; Mrs. John Blommer, St. Cloud; M. Jerry Mackin, Cedar Rapids, Iowa; Mrs. R. C. Seton, Long Beach, California; five sisters: Mrs. Ma Plancisky, Mrs. Edward LeSczen, and Mrs. Carl Fischer Montgomery, Minnesota, Mrs. Elmert Stemper, St. Paul and Mrs. Fred Pomeji, St. Cloud; one brother Stephen Santa Rosa, California, and three grandchildren.

ANDREW SIVERTSEN

Dr. Andrew Sivertsen, Minneapolis urologist for many years, died June 8, 1957. He was seventy-seven years old.

A graduate of Marquette University Medical School, Dr. Sivertsen maintained an office at 522 LaSalle Building for a number of years.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

LUDWIG L. SOGGE

Dr. Ludwig L. Sogge, noted Windom physician for over fifty years, died July 3, 1957. He was seventy-eight years old.

Born in Jackson county, Minnesota, Dr. Sogge attended Red Wing Seminary and received his medical education at the University of Minnesota. After interning at Swedish Hospital in Minneapolis he moved to Windom in 1906. Dr. Sogge purchased the land and was instrumental in building the Windom Hospital; he served as first president of its staff.

Long-active in medical association activities, he was past president of the Minnesota State Medical Association and chairman of the public policy committee for many years.

He was honored by his community, by the state medical association, and by the Southwestern Minnesota Medical Society in 1955 for attaining his fiftieth year in the practice of medicine.

Dr. Sogge was active in the Minnesota Tuberculosis and Health Association and the Cottonwood County Tuberculosis Association. In 1948 he was named Minnesota's outstanding general practitioner. Recently the Windom Good Samaritan Home for the Aged changed its name to the "Sogge Memorial Home" to honor the popular physician.

Dr. Sogge served as mayor of Windom for five years and as Cottonwood county coroner for eighteen years. He belonged to the Methodist Episcopal Church, the Community Club of Windom, the Masonic order and the Odd Fellows. In addition to his county and state medical affiliations, he was a member of the American Medical Association, the Southern Minnesota Medical Association and the Sioux Valley (Iowa) Medical Association.

He is survived by two daughters, Mrs. Alfred Nerdah and Mrs. Elvin Nordby of Windom; three grandchildren one brother, Dr. Tillman Sogge, Northfield; four sisters Mrs. Wilbur Morgan and Mrs. Anton Olson, Minneapolis; Mrs. Morris Bakken, San Diego, and Mrs. Hannah Meium, Jackson. Mrs. Sogge died in February 1957.

IN MEMORIAM

GEORGE E. THOMAS

Dr. George E. Thomas, well-known Minneapolis physician, died June 10, 1957. He was seventy-nine years old.

A native of Berlin, Wisconsin, Dr. Thomas graduated from the University of Minnesota Medical School in 1904. He practiced at Lake Street and Nicollet Avenue in Minneapolis for fifty-one years and was the first doctor to deliver an incubator baby in Minneapolis. He closed his office last December 1.

He served on the faculty of the University of Minnesota Medical School and was chairman of the first cancer committee formed by Dr. William W. Mayo in 1918.

Dr. Thomas was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association, the American Academy of General Practice, the University Baptist Church, the Ark Masonic Lodge, the Modern Woodmen of America and was a charter member of the Minnesota Alumni Band Association. He was also a member of the staff of Asbury Hospital.

Survivors include his daughter, Mrs. Robert L. Upton, Minneapolis.

URBAN H. ZEE

Dr. Urban H. Zee, Mankato, Minnesota, orthopedic surgeon, died March 28, 1957. He was forty-three years old.

A native of Ethan, South Dakota, Dr. Zee was a

graduate of the University of South Dakota and Creighton University Medical School, Omaha, Neb. He interned at St. Joseph's Hospital in Omaha and took his specialized training at the University of Minnesota Hospitals.

Dr. Zee spent over five years in the United States Army; he was attached to the University of Minnesota hospital unit in Europe and was with the U. S. Army band center at William Beaumont General Hospital. He was in general practice in Texas for four years.

A member of the Blue Earth County Medical Society, Dr. Zee also belonged to the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Patricia Ann.

CORRECTION

MINNESOTA MEDICINE regrets that because of misinformation, the death of Dr. Henry M. Lee of Cambridge was erroneously reported in the July, 1957, issue. Many apologies to Dr. Lee, his family and friends for this error. Dr. Lee is currently on the staff of the state hospital in Cambridge and a member of the East Central Minnesota Medical Society.

Veterans administration hospitals are safe places for volunteers to work, so far as danger of getting tuberculosis goes. Although tuberculosis afflicts about one out of every 1,000 persons in the general population, a survey of VA hospitals and other installations showed not one of 11,375 volunteer workers developed the disease after coming on duty.—News Item, *Science News Letter*, November 3, 1956.

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

F. H. Magney, M.D., Secretary

SOUTH SAINT PAUL MAN SENTENCED FOR ATTEMPTED ABORTION

On May 15, 1957, Malcolm A. Leitch, forty-one, Route No. 1, South Saint Paul, Minnesota, was sentenced by the Hon. Ronald E. Hachey, Judge of the District Court of Ramsey County to a term of not to exceed two years in the State Prison at Stillwater for the crime of attempted abortion. The defendant had entered a plea of guilty before Judge Hachey on April 24, 1957, to an information charging him with that offense. However, Judge Hachey stayed the execution of the sentence and placed Leitch on probation for a period of two years. After sentencing the defendant, Judge Hachey told him that his crime was a very serious one and he was being placed on probation only because the Court was convinced that the defendant had been misled and would not repeat the offense.

The case involving the defendant came to the attention of the Minnesota State Board of Medical Examiners when a twenty-four-year-old Saint Paul divorcee, the mother of two children, sought medical care at a Saint Paul hospital for her pregnant condition. The patient stated that Leitch had attempted to abort her on four occasions by means of a catheter in an apartment on Dayton Avenue in Saint Paul. According to the woman's signed statement, the person responsible for her pregnancy was the manager of an encyclopedia sales office in Saint Paul. A signed statement was also taken from this man, who admitted that he had arranged for the defendant to perform the abortion and that he had paid Leitch \$70.00 or \$80.00 in cash for his services, in addition to assuming for six months the \$12.00 monthly payments on a \$298.00 set of an encyclopedia for Leitch.

Leitch, who has a large family and lives on a farm near South Saint Paul, holds no license to practice any form of healing in the State of Minnesota. At the time of his arrest, a number of medical instruments were found in the defendant's home, including a speculum, forceps, hemostat, bandage scissors and three catheters. The defendant stated that he graduated from Johnson High School in Saint Paul and that he attended the University of Minnesota for four years but did not complete his course.

TWO UNIVERSITY OF MINNESOTA GRADUATE STUDENTS CHARGED WITH ABORTION

Demetrios Constantine Economou and Dr. Anshumar Antikiel Roy were charged with the crime of abortion in a complaint issued on May 11, 1957, by the Hennepin County Attorney's office and signed by a representative of the Minnesota State Board of Medical Examiners. Economou, twenty-four, a citizen of Greece, was at that time a student in physical chemistry in the Graduate School of the University of Minnesota. Dr. Roy, thirty-three, a citizen of India, who was taking postgraduate work in pediatrics at the University of Minnesota, claimed to be a graduate in medicine from the Ahmadabad Medical School, Ahmadabad, India.

When the defendants appeared before the Hon. Dana Nicholson, Judge of Minneapolis Municipal Court, on May 14, 1957, they denied that the Court had jurisdiction over the case because they were aliens. However, Judge Nicholson did not agree with their contention and bound both defendants over to the District Court of Hennepin County for trial. After the defendants had entered a plea of not guilty before the Hon. John

A. Weeks, Judge of Hennepin County District Court, conferences were held with representatives of the United States Immigration and Naturalization Service, and the cases of both defendants were disposed of in a similar manner.

On May 27, 1957, the defendant Roy appeared again before Judge Weeks, at which time a representative of the Hennepin County Attorney's office made a motion to the Court that the case be stricken from the trial calendar on condition that the defendant leave the United States of America within a period of thirty days and that he emigrate to a country that is non-contiguous to the United States. The Court then ordered that the case be dropped from the trial calendar on those conditions. When the defendant Economou appeared on June 3, 1957, before the Hon. Earl J. Lyons, Judge of the District Court of Hennepin County, a motion was made to the Court that the case be stricken from the trial calendar on condition that the defendant leave the State of Minnesota and complete his two and one-half years of graduate training elsewhere. The Court then granted the motion and ordered the defendant to return to his native country of Greece at the expiration of that period.

The defendants were arrested after the authorities received information that a twenty-two-year-old unmarried Minneapolis woman had undergone a criminal abortion. When the woman was questioned, she alleged that Demetrios Economou had been responsible for her pregnancy and that he had paid the defendant Roy the sum of \$100.00 for performing an abortion upon her. The illegal operation took place in the room where Economou was living while attending the University. The defendant Roy is not licensed to practice medicine in Minnesota, nor does Economou hold a license to practice any form of healing in this state. If either of the defendants violates the order of the Court, the case can be placed back on the trial calendar and the defendant will have to stand trial.

PHYSICIAN'S LICENSE REVOKED

On May 25, 1957, the license to practice medicine held by George F. Engstrom, M.D., fifty-four years of age, Belgrade, Minnesota, was revoked by the Minnesota State Board of Medical Examiners. Dr. Engstrom had been charged in a citation issued by the Board with immoral, dishonorable and unprofessional conduct as defined by law in that he had been convicted of a felony. When he appeared before the Minnesota State Board of Medical Examiners on May 24, Dr. Engstrom admitted the truth of the citation, which further charged that on or about April 22, 1957, Dr. Engstrom had been convicted in the District Court of the United States, State and District of Minnesota, Third Division, of filing and causing to be filed with the Collector of Internal Revenue at St. Paul, Minnesota, a false and fraudulent income tax return for the calendar year 1950.

It was also brought to the attention of the Board that the indictment, to which Dr. Engstrom had pleaded guilty on February 25, 1957, before the Hon. Dennis F. Donovan, Judge of United States District Court, had charged Dr. Engstrom with filing on behalf of himself and his wife, a false and fraudulent income tax return for the calendar year 1950, "wherein it was stated that their net income for said calendar year was the sum

PHYSICIAN'S LICENSE REVOKED

(Continued from Page A-32)

of \$8,673.50 and that the amount of tax due and owing thereon was the sum of \$909.04, whereas, as he then and there well knew their joint net income for the said calendar year was the sum of \$24,375.47 upon which said net income there was owing to the United States of America an income tax of \$5,040.96 * * *." On April 22, 1957, Judge Donovan sentenced Dr. Engstrom to serve one year in prison and pay a fine of \$7500. However, Judge Donovan suspended that portion of the sentence which provided for the prison term and placed Dr. Engstrom on probation for a period of five years. Dr. Engstrom paid the fine immediately.

Dr. Engstrom's medical license had been previously suspended for a period of three years by the Minnesota State Board of Medical Examiners on February 14, 1953. At that time, he admitted that between January 1949, and June 18, 1952, he had prepared "numerous fictitious, fraudulent and excessive claims for remuneration for professional services * * *." The fictitious, fraudulent and excessive claims made out by Dr. Engstrom were submitted to various insurance companies and other groups covering hospital and medical care benefits. Although the Minnesota State Board of Medical Examiners at that time was of the opinion that Dr. Engstrom's misconduct warranted a permanent revocation of his license, some measure of leniency was extended to him in view of the fact that he had made full and complete restitution to all of the insurance companies involved. In connection with the same matter, Dr. Engstrom had entered a plea of guilty in the District Court of Ramsey County on July 14, 1952, to an information charging him with grand larceny in the second degree. On May 4, 1953, Dr. Engstrom was sentenced for this offense by Judge Arthur A. Stewart to a term of one year in the Ramsey County jail. However, the Court stayed the execution of the sentence for a period of one year upon the defendant's good behavior.

Dr. Engstrom was born in Sweden on April 5, 1903, and received his M.D. degree from the University of Minnesota in March, 1928. He was licensed by examination by the Minnesota State Board of Medical Examiners in July, 1927, upon receiving his Bachelor of Medicine degree. He has been located at Belgrade, Minnesota, since August, 1928.

MINNEAPOLIS MAN SENTENCED TO FOUR-YEAR PRISON TERM FOR ABORTION

On June 13, 1957, Ray G. Erickson, forty-four, 2019 Second Avenue S., Minneapolis, was sentenced by the Hon. John A. Weeks, Judge of the District Court of Hennepin County, to serve a term of not to exceed four years in the State Prison at Stillwater, pursuant to his plea of guilty, which he had entered before Judge Weeks on May 14, to an information charging him with the crime of abortion. In a complaint issued by the Hennepin County Attorney's office, Erickson and the defendant, Bart Setchell, forty-nine, 476 Woodlawn Avenue, Saint Paul, had been charged with committing the offense of abortion on or about May 2, 1957.

When the defendant Setchell was arraigned on the abortion charge in Hennepin County District Court before the Hon. Paul S. Carroll on May 14, he entered a plea of not guilty and the case was set for trial on May 27. When Setchell appeared before Judge Weeks on the latter date, the charge against him was reduced to a gross misdemeanor, practicing healing without a basic science certificate. After Setchell had entered a plea of guilty to the basic science violation, Judge Weeks sentenced him to pay a fine of \$1,000.00, the maximum fine for a gross misdemeanor, and the defendant paid the fine immediately.

The criminal complaint against the defendants, which was signed by a representative of the Minnesota State Board of Medical Examiners, was issued after an investigation disclosed that a thirty-two-year-old Newport, Minnesota, divorcee had been hospitalized at Ancker Hospital in Saint Paul suffering from the after-effects of an abortion. The patient stated that she became pregnant by the defendant Setchell and on May 2, 1957, she received \$300.00 from him to pay for an abortion. The patient then followed instructions and went to a Minneapolis drug store where a man contacted the defendant Erickson, who performed the abortion in his home on that same day by the use of a catheter. The woman said she then paid Erickson \$300.00.

The defendant Erickson stated to Judge Weeks at the time he was sentenced that he was born in Kenyon, Minnesota, on January 2, 1913 and completed two years of high school there. He gave his occupation as being self-employed, living from income property. Although Erickson denied that he had received any compensation for performing the abortion, Judge Weeks told him that he did not believe that he was telling the truth. The defendant Setchell is the president of Setchell-Carlson, Inc., a New Brighton radio and television manufacturing firm. Neither of the defendants hold a license to practice any form of healing in the State of Minnesota.

DOCTORS ADVISE AGAINST LETTING BABIES "CRY IT OUT"

The era of letting babies "cry it out" is over, states a bulletin from the Minnesota State Medical Association. Today doctors advise returning to a more natural and far more sensible attitude in respect to our youngest citizens, that is treating and accepting them as very human beings with justifiable demands to be met and unquestionable needs to be filled. One of the things that disturbs a mother most is what to do when the baby cries. Should she let him "cry it out" or should she pick him up every time he howls?

Basically, the infant cries because it is his only means of communication with the outside world; most of the time the crying means mealtime is overdue. Sometimes it means he is uncomfortable in soiled diapers or feels too warm. Again, and often, the cause of crying is simply unknown. When this happens, the best answer doctors can give is "the more care, the less crying." Studies have shown that babies cry less when they are cared for more. Having his mother around him, being handled and fondled by her not only reduces the baby's need to cry but has strong positive effects on his health and emotional development as well. It is not a good idea to allow a young baby to "cry it out," because the crying is not good for him. It causes disagreeable sensations, perhaps even pains and can end in complete exhaustion.

When the child wails, first check the obvious physical needs; then if all else seems to be in good order, hold him a bit, rock him, sing to him. Let him know how much you love and want him.

It is true that some babies cry more than others. Doctors group them into three general categories: quiet, moderately active, and active. The quiet baby is better able to tolerate stimulation, while the active child with his more acute responses may require more comforting and needs to be held more and given more reassurance.

Some parents fear that the attentions given a crying child may spoil him and may make the attention a habit. This is not so because the baby whose physical needs have been supplied, who has received adequate mothering and love actually requires less and less of such attention as he grows older.

Cleans like magic . . . no more scrubbing with **KLER-RO®**

ULMER

For surgical instruments, laboratory glassware, rubber goods and linens.

Soaks clean . . . removes dried blood, pyrogens, plasma, serums and mucus . . . eliminates necessity of hand scrubbing.

Will not etch glassware, leaves it sparkling clean. Will not pit stainless steel. Has a nearly neutral pH. Kler-ro does not cake but dissolves quickly and is safe and economical to use.

MINNESOTA BLUE SHIELD-BLUE CROSS

Effective July 1, 1957, the Minnesota Blue Shield Board of Directors extended in-hospital medical care or combined surgical and in-hospital medical care benefits from 120 to 180 days for each unrelated illness during twelve consecutive months. This extension of in-hospital medical care benefits is only the latest of a number of improvements and extensions of medical care benefits made by Minnesota Blue Shield in less than ten years of operation, all of which indicate a desire on the part of the Blue Shield Board of Directors to provide a well balanced contract as well as coverage commensurate with improved methods of medical care.

The original Minnesota Blue Shield contract provided benefits for a maximum of twenty-one days of in-hospital medical care for each unrelated illness during twelve consecutive months. The first extension of in-hospital medical care benefits occurred August 1, 1949, when emergency medical care was added to the contract. On October 1, 1952, allowances for the first three days of emergency in-hospital medical care were increased and in-hospital medical care benefits were extended from twenty-one to thirty days.

Again, January 1, 1954, Blue Shield increased allowances for the first two days of regular in-hospital medical care, the first two days of emergency in-hospital medical care, and extended in-hospital medical or combined surgical and in-hospital medical care benefits from thirty to seventy days. At this time consultation benefits were made available to physicians for services on behalf of participant subscribers.

Further improvements in medical care benefits of the Minnesota Blue Shield contract were accomplished July 1, 1955, when intensive hospital medical care was added to the contract. Consultation fees were increased at this time as were Plan B fees for the first thirty days of regular and emergency in-hospital medical care, and benefits for in-hospital medical care or combined surgical and in-hospital medical care were extended from seventy to 120 days for each unrelated illness during twelve consecutive months.

The most recent extension of in-hospital medical care coverage for services rendered on and after July 1, 1957, should be of particular importance in the treatment of cancer, burns, cardiovascular cases and other diseases requiring prolonged care in the hospital.

During the month of May, 1957, Minnesota Blue Cross provided over \$2,500,000 in hospital benefits 18,276 participant subscribers. Days of care provided during May totaled approximately 10,000.

This new high in hospitalization experience represented not only a peak month in dollars, days and case but also in incidence of use of Blue Cross coverage. During May, 1957, 523 contracts out of every 1,000 protected, utilized their Blue Cross benefits. Compared to May, 1956, this was an increase of forty-two cases paid per 1,000 contracts protected.

The increases occurred in the categories of obstetric care and accident cases.

During the first five months of 1957, Blue Cross payments to hospitals totaled \$11,899,357.09, compared to \$9,715,871.80 for the same period of the previous year.

The 85,515 hospital cases paid during this period of 1957, represented 527,764.1 days of hospital care compared to 471,729.3 days of hospital care incurred by 76,139 Blue Cross subscribers during the same period of the previous year.

During the first five months of 1957, incidence rate was 493 cases per 1,000 contracts protected, compared to 471 cases per year. Accident cases were again a major factor in this five-month increase. However, other diagnostic classifications such as obstetrical, respiratory illnesses, neoplasms and nervous diseases also showed an increase over the same period in 1956.

Blue Cross enrollment in Minnesota as of May 31, 1957, totaled 1,114,119 participant subscribers compared to 1,048,607 as of May 31, 1956. The number of effective contracts was 422,519 as of May 31, 1957 compared to 395,999 contracts in effect as of May 31, 1956.

Over-all, the \$2,183,485.29 increase in payments to hospitals for the first five months of 1957, over the same period in 1956 was attributable to: (1) increase in usage, (2) increase in Blue Cross enrollment, and (3) continuing trend to higher benefit level of contracts.

Book Reviews

Books listed here become the property of the Ramsey Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

RYPINS' MEDICAL LICENSURE EXAMINATIONS: TOPICAL SUMMARIES AND QUESTIONS.

Walter L. Bierring, M.D., M.A.C.P., M.R.C.P., Ed. (Hon.), with the collaboration of a Review Panel. Ed. 8, 964 pages. Price \$10.00. Philadelphia: J. B. Lippincott Co., ©1957.

Most persons feel the need for review before taking an examination. Medical licensure examinations are no exception. Following Dr. Harold Rypins' original plan to write "separate summaries of each subject and answer questions based on the essential facts contained in each summary," Dr. Bierring has brought out the eighth edition of this book. The contents are divided into the Basic Medical Sciences and the Clinical Sciences.

Although there are several changes from the preceding edition in the panel of reviewers, the text has adhered quite closely to the previous text. However, paragraphs have been added here and there to bring material up to date or to amplify statements where it was felt amplification was needed. Revisions have been made to include some of the newer knowledge, as in enzymology, allergy, antibiotics, tranquilizers, atomic war burn casualties, Salk vaccine. Some subjects, like mastoiditis, which are succumbing to antibiotics and chemotherapy, were omitted; and older concepts, which are being replaced, were left out.

The introductory chapter on examinations has been revised to include a description and examples of the objective multiple-choice written tests as developed by the National Board of Medical Examiners.

Many have found the earlier editions of this book to be a useful outline to have at hand when reviewing for licensure and other examinations, and surely the latest edition will be equally as popular.

NEW FILM ON PROFESSIONAL LIABILITY HAZARDS

A new film that shows physicians how to avoid the recurrent headache of medical practice today—the professional liability claim—is now available from the American Medical Association film library for court society and other professional bookings.

Titled "The Doctor Defendant," the new film was premiered this week (June 5) in the New York Cosmos before a large audience of physicians attending the 106th annual meeting of the AMA. The 34-minute black-and-white sound film is the second in the "Medicine and the Law" film series produced by the Wm. Merrell Company, ethical pharmaceutical laboratories, Cincinnati, Ohio, in cooperation with the AMA and the American Bar Association.

The new movie presents in concise and dramatic terms the stories of four doctors who find themselves cast in the disturbing role of "The Doctor Defendant." In reviewing these cases, the film also demonstrates how

county medical society professional liability review committee functions.

Medical societies may now book "The Doctor Defendant" from the AMA film library for showings before their own members. "The Doctor Defendant" is a companion film to "The Medical Witness" which depicts right and wrong methods of presenting medical testimony by re-enacting a personal injury trial. Both films can be booked together as part of a legal medicine seminar.

Produced as a service to the medical and legal professions, "The Doctor Defendant" presents four cases which are among the most frequently encountered and most representative of what the physician has to face.

The first case is that of a physician charged with negligence in causing a burn during x-ray therapy. In another case the doctor is sued because a doctor unthinkingly criticizes the way an orthopedic patient has been treated. In the third, a claim of unnecessary surgery is made, and in the last case a physician is sued when he advises his patient by telephone and an unfortunate result occurs.

All are common situations; however, they are situations about which the physician is generally poorly informed. "The Doctor Defendant" dramatically explains the legal basis on which these suits are brought, and the areas in which the physician is vulnerable. It shows the best methods to avoid involvement and offers concrete advice on how the physician should handle himself once he has been made the target of a professional liability claim.

Special reference is made to the professional liability review committees that have been set up by some of the county medical societies. The film shows one of these committees in action and how it serves the public and the physician member who is in trouble.

Here are seven suggestions for the practicing physician who wishes to avoid liability involvement, as illustrated by "The Doctor Defendant":

1. Explain to the patient the proposed course of therapy and advise him when treatment may be hazardous.
2. Confirm in a letter to the patient the effects of treatment when harmful side actions or results might be expected. Obtain written consent for operative procedures. *Remember to keep a copy for your file.*
3. Review and interpret the clinical significance of all diagnostic or laboratory tests *before* a surgical procedure.
4. A precipitating cause of a large number of professional liability actions is the unthinking comment of physician on treatment given a patient by another physician. All the facts may not be known . . . so avoid tactless comment.
5. Always remember the protective value of a complete case record. It has been shown again and again that the doctor's best defensive tool in a professional liability claim or suit is the detailed case record.
6. All professional liability claims should be reported promptly to the proper persons; this may save time and unnecessary legal involvement.
7. Be constantly aware of the physician's responsibility to the patient. It is the physician alone who must decide the medical care to be provided.

Societies desiring to show "The Doctor Defendant" and/or "The Medical Witness" may write to the Film Library, American Medical Association, 535 No. Dearborn Street, Chicago 10, Illinois, or to Dr. John B. Thewning, director of professional relations, The Wm. C. Merrell Company, Cincinnati 15, Ohio.

Original Contributions

Experimental Fatty Cirrhosis

F. W. HOFFBAUER, M.D.
Minneapolis, Minnesota

THE RETIRING president of the Minnesota Pathologic Society is permitted to select his own topic for this address. As a physician interested in diseases of the liver, I have chosen one aspect of an inexhaustible subject, cirrhosis. My remarks will be limited to a single form of experimental cirrhosis, namely fatty liver disease in the rat. I should like to describe a classification that we have found useful for grading specimens in the laboratory and in so doing offer some comments on the transition of fatty liver to cirrhosis. No direct correlations with human liver disease is intended nor implied, though some generalizations applicable to the problem of cirrhosis in man may be derived from a study of this disorder in lower animals.

A physician viewing a cirrhotic liver demonstrated to him at the autopsy table realizes that this grossly distorted organ is the end stage of a long continued process. However, it is difficult for him to visualize the manner by which the liver has been converted from a smooth organ of regular texture to such a disorganized structure. A description of the developmental processes in one form of experimental cirrhosis may help somewhat in understanding the transitions that occur in the disorder. In the experimental laboratory one can, by relatively simple means, initiate a process in an animal that will eventuate in cirrhosis. The opportunity is afforded whereby one can observe the sequence of events that takes place.

For many years the basic concepts in the development of cirrhosis have, with much justification, included degeneration, fibrosis and regeneration. The modern concept of this disorder has been concisely stated by Popper.¹ Cirrhosis can be

said to exist when there is "altered reconstruction of the lobular pattern with the formation of regenerative nodules." This concept is accepted by Baggenstoss² and by Karsner.³ Emphasis is put upon reconstruction and particularly upon regeneration. Popper and Schaffner⁴ stress the importance of the intrahepatic vascular anastomoses as well as the regenerative nodules in cirrhosis. The intrahepatic shunts that develop in cirrhosis certainly deserve more adequate consideration than they have received in the past. Very likely they are often unrecognized because they are difficult to detect in microscopic sections.

This presentation will attempt to emphasize the role that *regeneration* plays in the reconstruction of the liver in one form of experimental cirrhosis. This is done in the belief that the aspect of regeneration, while not neglected, has not received the consideration that it deserves. Too much emphasis has been placed on fibrosis. In many descriptions of cirrhosis, the impression is conveyed that fibrosis is an active process, embracing and compressing the liver cells. Actually the fibrous tissue, as it is seen in experimental fatty cirrhosis, appears to represent a condensation of the residual supporting tissue that remained after the parenchymal cells have disintegrated. This supporting frame work, together with the bile ducts, veins, arteries and lymphatics, has been compressed into fibrous membranes by the newly regenerating liver cells.

In order to produce cirrhosis experimentally, widespread death of liver cells is necessary so that excessive regeneration will be forced to occur. One seeks an agent that is capable of destroying some but not all of the parenchymal cells. For this purpose, carbon tetrachloride has been a popular agent. Repeated sublethal doses of carbon tetrachloride cause waves of destruction to sweep over the liver, and a form of cirrhosis develops. In recent years another method of producing experimental cirrhosis has become available. This is

From the Department of Medicine, the Medical School, University of Minnesota.

This investigation was supported by the Research and Development Division, Office of the Surgeon General, Department of the Army, under Contract No. DA-9-007-MD-592.

Presented before the Minnesota Pathological Society, March 20, 1956 at Minneapolis, Minnesota.

a fatty cirrhosis that is the result of a nutritional liver injury. This method offers certain advantages and the disorder that results may bear a relationship to liver disease as it occurs naturally. With information now available, diets deficient in lipotropic factors (choline or its precursor, methionine) can be readily devised. In the rat, a diet deficient in the precursor of choline but adequate in other respects leads to an intensely fatty liver. This situation, if allowed to exist for a period of time, regularly leads to the development of cirrhosis. The investigator has at his disposal a method by which he may follow the sequence of events over a period of weeks or months. The remarkable progress made by many investigators in this field of experimental liver injury has been recently reviewed by Hartroft.^{5,6}

In the course of experiments involving rats maintained for varying lengths of time on diets deficient in choline, the need arose in our laboratory for a system of pathologic classification. The hepatic pathology was not uniform at given intervals even though experimental conditions appeared to be identical. The factor of "time" or *duration* alone did not adequately express the pathologic picture. Descriptions based on the amount of fat or fibrosis present proved unsatisfactory. Therefore, a classification based upon regenerative responses and divided into four stages as described in Table I was devised. This proved to be useful for our purposes and has been employed for the past several years.

Experimental Methods

Rats of a uniform strain* were employed in these studies. Animals were kept in individual cages suspended in racks† in an air conditioned, continuously illuminated room. The relatively wide mesh wire bottoms of the cages permitted fecal pellets to drop out of reach of the animal. This is a matter of some importance in the evaluation of the results in animals fed restricted diets. Because of coprophagia, the rat can ingest a sufficient amount of bacteria or bacterial products to alter the results of long term feeding experiments. The hypolipotropic (choline deficient) diet used in the present experiments contained 8 per cent casein. The composition of this diet, C-8, is given in the accompanying table.

The animals were allowed 8 grams of the diet per day. Ointment jars without tops make satisfactory feeding cups; the feeding mixture is sticky and spillage is minimal. Food was distributed in two or three day allotments three times each week. All uneaten food was discarded on feeding days. Food consumption was not

measured. The feeding mixture was prepared once each week and refrigerated. The three supplemented diets (C-8 A, B and C) contained .05 per cent, 0.2 per cent and 0.4 per cent choline chloride. The choline was added to the C-8 diet and the amount of sucrose correspondingly reduced.

An extensive experience with diet C-8 over a six-year-period in which the same method of preparation, storage and feeding was used indicated that it is definitely hypolipotropic. Severe fatty infiltration of the liver regularly occurs in the rat. Very young male rats usually succumb to hemorrhagic necrosis of the kidneys in fourteen to eighteen days, an indication of the deficiency of this diet in choline. The diet in the amount of 8 grams per day is adequate for growth until the adverse effects of long continued fatty infiltration of the liver become manifest. When the diet is supplemented with choline, the animals remain healthy and growth is adequate considering the restricted nature of this 8 per cent casein diet (45 calories furnished per day). The non-supplemented diet was estimated to furnish approximately 22.4 mg. of methionine and 54 mg. of cystine per day.

In the course of these experiments, specimens were obtained at death, or the animals were sacrificed by anesthetizing with ether and bled by severing the abdominal aorta. The right lateral lobe of the liver was preserved intact in 10 per cent neutral formalin. Longitudinal slices from the left lobe were fixed in neutral formalin or Bouin's fluid, then sectioned and stained with H & E, azo carmine and Oil Red O for histologic studies. Frozen sections were cut 15 microns thick for fat stains.

Experimental Results

The classification utilized in present report is based upon the gross and microscopic features of the livers from 106 rats maintained on a choline-deficient diet (Diet C-8) and from fifty-six rats maintained on the same diet supplemented with choline. The data shown in Table I and in Figure 1 indicate the stages of fatty liver disease reached when the animals died or were sacrificed.

In fatty liver disease in the rat, the resultant liver pathology demonstrable at any given time is determined by the prevailing experimental conditions. For instance, if the experiment is begun with young rapidly growing animals, the various stages are attained earlier than when one commences with older animals. Female rats appear to tolerate choline deficiency better than do males. Furthermore, the character of the diet influences the degree of fat accumulation and consequently the rate of cell destruction.

The gross appearance of the liver in various stages of the development of fatty cirrhosis in the rat is shown in Figure 8. The right lateral lobe of the liver, after formalin fixation, has been employed for these illustrations. The liver is transformed from an organ of uniform texture and smooth surface to a completely irregular nodular structure. In the process it passes through a phase of uniform and equal enlargement of individual areas that results for a time in a hyperplastic liver. A description of the sequence of events in the development of experimental fatty cirrhosis has been illustrated in a series of diagrams shown in Figure 2. The figures are entirely schematic; on microscopic examination one could never see such an arrangement. No section of liver tissue ever contains nine central veins and twelve terminal portal veins in one microscopic field. One of the greatest handicaps to the understanding of the structural changes that occur in cirrhosis is

Fig. 1. Time relationship between stages of fatty liver disease attained and the degree of choline deficiency.

The diet, C-8, fed to 106 rats, resulted in severe fatty liver disease. As indicated by the arrow, the time relationship is roughly linear. Seventeen rats received diet C-8 B, i.e., the experimental diet supplemented with 0.2 per cent choline. In this group of animals, sacrificed at intervals up to 184 days, six showed only centrilobular fat (Stage I), and eleven exhibited no histologically demonstrable fat in the liver. Among the seventeen rats maintained on the diet C-8 A (.05 per cent choline supplement), six remained at Stage I. The remainder attained variable degrees of cirrhosis but always less pronounced than in animals severely deficient in choline.

the necessity of examining liver specimens in only two dimensions i. e., a thin slice of tissue viewed under the microscope. The organ has three dimensions and the pathologic changes are three dimensional, a fact well appreciated and beautifully illustrated in the recent studies of Popper and Elias⁷ and Kelty, Baggenstoss and Butt.⁸ Realizing the limitations of an oversimplified two-dimensional approach to a three-dimensional problem, the series of drawings in Figure 2 represent an attempt to portray, in terms of "stages," the changes that occur in the liver of rats as a result of continuous severe accumulation of fat.

Stage I. Centrilobular Fat.—The first histologic evidence of choline deficiency in the rat is the ac-

Fig. 2. Schematic representation of the four stages of fatty liver disease in rats maintained on diets severely deficient in choline.

The small black circles represent central veins. The small black triangles represent *terminal* branches of the portal vein and not the large or conducting branches. Bile ducts and hepatic artery branches are not presented in the diagrams. The accumulation of intracellular fat in the liver is represented by the stippled areas. The formation of fatty cysts is depicted by the minute open circles. The white areas indicate non-fatty cells, i.e., areas in which fat accumulation has not yet occurred (Stage 1) or newly formed (actively regenerating) cells that have not yet become fatty (Stage 3a). The new formation of liver cells and the pressures exerted by this regenerative activity are indicated by the crossed arrows. The trabecular pattern produced by the membranous septa that course from central vein to central vein is determined by the pressure produced by areas of regeneration, uniform in Stage 3, irregular in Stage 4. The regenerative nodule is depicted in the diagrams in Stage 4 A and 4 B.

cumulation of fat droplets in the cells adjacent to the central veins. Stage I has been designated as that in which one-half of the cells of the liver lobule are laden with fat droplets, as shown in Figures 2 and 3. In *severe* choline deficiency, there is no abrupt cessation of fat deposition in the liver, as the term "stage" might suggest. However, when minimal amounts of choline are added to

the diet, the degree of fatty infiltration may not progress beyond this stage. As can be seen from the data in Table I and in Figure 1, animals that received supplements of choline in amounts of 0.2 or 0.4 per cent (Diets C-8 A and C-8 B), either showed no fat in the liver or the accumulated fat remained confined to the centrilobular area. This was true even though some animals were continued on the supplemented diet as long as 180 days before sacrifice. There were no other pathologic changes in the livers of these animals. A moderate degree of fat accumulation limited to the central vein area may exist in the liver for prolonged periods without producing any structural alteration. To produce structural changes in the liver, hepatic steatosis must be severe. Fat must accumulate in liver cells to such an extent that the cells are actually ruptured by the large droplets. The classic studies of Hartroft^{9,10,11} have clearly demonstrated this. Failure to appreciate this aspect no doubt has led to some confusion regarding the role that fat plays in the production of experimental cirrhosis.

Stage II. Entire Liver Fatty.—Severe choline deficiency in the rat leads quickly to a state in which the entire liver lobule becomes fatty (Figs. 2 and 4). This has been designated Stage II. Now every liver cell contains fat and those adjacent to the central veins have become so distended with fat droplets that they have ruptured and formed, by fusion with adjacent ruptured cells, fatty cysts.

The formation of fatty cysts, so clearly described by Hartroft^{9,10,11} is a basic and fundamental mechanism by which liver cells in the choline-deficient rat are destroyed or at least rendered useless as functioning cells. There can be no doubt of the existence of fatty cysts. They can be visualized by inspection of unstained fresh or formalin fixed fatty liver specimens under the dissecting microscope. It is obvious from their size that their walls are composed of the remnants of many liver cells. When they have formed in abundance, the liver has obviously been deprived of a large number of functioning cells.

Stage II in fatty liver disease may be regarded as a critical one for the life of the animal. The well known enormous functional reserve of the liver has now been greatly reduced and the animal is in a hazardous state. Nature has, in effect,

Fig. 3. (*Upper left*) Photomicrograph (H & E, low power) Stage I of fatty liver disease in the rat. The accumulation of intracellular fat is limited to the areas about the central veins. The areas about the portal veins and particularly the terminal branches of this venous system have, as yet, been spared.

Fig. 5. (*Lower left*) Photomicrograph (H & E, low power) Stage III A of fatty liver disease in the rat. Newly formed and therefore non-fatty cells are beginning to appear about the areas nourished by the terminal branches of the portal vein. Pressures will be exerted by each of these areas of active regeneration. The fatty cysts link central vein to central vein.

performed a partial hepatectomy in the sense that the rat has been deprived of a great deal of his functioning liver tissue. The response to this situation is active regeneration—the formation of new liver cells. In order to appreciate fully the remarkable regenerative ability of the liver, one needs but consider the effects of a partial hepatectomy in the normal animal. The surgical removal of two-thirds of the liver in the normal rat is followed by a dramatic regeneration of liver cells in all parts of the remaining liver lobules. The result is that in a few days each lobule of the residual liver lobes has increased in size; even-

Fig. 4. (*Upper right*) Photomicrograph (H & E, low power) Stage II of fatty liver disease in the rat. The accumulation of fat involves the entire liver lobule. Fatty cysts (scarcely discernible at this magnification) are beginning to form in the areas about the central veins. The areas about the terminal portal veins are difficult to recognize. All the parenchymal cells contain fat droplets.

Fig. 6. (*Lower right*) Photomicrograph (H & E, low power) Stage III B of fatty liver disease in the rat. Trabeculae link central veins and large conducting portal veins. The location of these fibrous strands (membranous septa cut on edge) is determined by the pressures and counter pressures exerted by the myriads of areas of liver cell regeneration each centered about the terminal branches of the portal veins.

tually the animal has a liver that weighs as much as the original one and functions normally. In that situation, the portion of the liver that has been left behind after extirpation of two-thirds is normal in structure. It regenerates uniformly. The situation in the rat with extensive fatty infiltration is quite different. The original structure still remains although the number of functioning units is greatly reduced. The stimulus to regenerate—in all probability a humoral mechanism exists that dictates to the liver that it must create more cells—is operative. Regeneration will be maximal in the areas that are the least fatty and

presumably the best nourished. These are the areas about the terminal branches of the portal veins, a fact appreciated by Ashburn, Endicott, Daft and Lillie¹² in 1947 and clearly demon-

Fig. 7. Diagrammatic representation of the mode of incorporation of areas about the larger or conducting branches of portal vein membranous septa.

In Stage III B, trabeculae not only link central vein to central vein areas but also the areas about the larger or conducting portal veins. The large black triangle in the center of this figure denotes a conducting portal vein (bile duct and artery omitted). The black circles denote central veins. The small triangles denote terminal branches of the portal vein (as in Figure 2). Forces exerted by areas of regeneration (depicted by arrows) could be responsible for the patterns assumed by the membranous septae (trabeculae) that are seen in experimental fatty cirrhosis in the rat.

strated more recently by Hartroft¹³. This area receives fresh blood first; for this reason and probably others, it constitutes the area best suited to take part in active regeneration. In severe choline deficiency, the sequence of events can be depicted as a prompt passage through Stage II, a stage in which the entire liver is fatty, into a third phase, Stage III, in which regeneration becomes a prominent feature. Actually, regeneration does commence before every cell in the liver lobule is involved by fat accumulation. The process of fatty liver disease in the rat is a dynamic one. The destructive forces, cellular disruption and the response, regeneration, go on simultaneously. For descriptive purposes it is convenient to consider the sequence of events as if they occurred in stages.

Stage III. Uniform Periportal Regeneration.—Stage III may be divided into an early aspect in which fibrosis is not yet apparent (III A) and a late and more prolonged aspect in which fibrosis is a prominent and conspicuous feature (III B). In the present description, emphasis is placed upon regenerative activity on the part of the cells

about the terminal branches of the portal vein. The formation of fatty cysts in the centrolobular areas has preceded active regeneration.

In Figure 2, the white circular areas with the crossed arrows (Stage III A) indicate regeneration occurring uniformly about each of the terminal portal veins. As this process continues, pressures will be exerted and the disintegrating fatty cysts about the central veins will be compressed. Figure 5 illustrates this regenerative activity about the terminal branches of the portal veins. It is difficult to depict this in a convincing manner in a single photomicrograph. Terminal portal vein areas are seldom found on the same plane as central vein areas in sections cut at 5 micra. Frozen sections cut at 15 micra reveal this phenomenon better, for the newly formed non-fatty cells stand out as "islands" in the intensely fatty liver.*

One of the characteristic microscopic features of early cirrhosis in the choline-deficient rat is the appearance of fibrous septa that link central vein to central vein. This nonportal trabeculation was demonstrated in the studies of Ashburn et al in 1947¹² and further elaborated upon by Hartroft in 1954¹³. The fact that the small terminal portal vein together with its accompanying bile duct, is not incorporated in the fibrotic trabeculae has been clearly demonstrated. The diagrams of Stages III A and III B in Figure 2 indicate regenerative activity predominating in certain areas. The resulting pressure from the expansion of these areas will determine the *pattern* of "fibrosis" in the liver as cirrhosis develops. The trabeculae that extend from one central vein to another appear in microscopic sections as strands or bands

* The mere absence of visible fat droplets in the cells of the periportal area of a given section of liver does not constitute unequivocal proof that these cells are newly formed. In the rat maintained on these choline-deficient diets, fat can be mobilized from liver cells very rapidly by modifying the experimental procedures. For example, the addition of even minute amounts of a lipotropic agent will, in a matter of twenty-four to thirty-six hours, mobilize fat from the liver. The first cells to give up the fat are those about the periportal areas. If an animal that has been fed a choline-deficient diet long enough to produce an intensely fatty liver is suddenly starved for thirty-six to forty-eight hours, some fat will leave the liver. Again, it is the periportal areas that will release the fat droplets. Unless the experimental conditions are known, it is difficult to interpret the significance of fat free cells in the periportal areas. The specimen used for the illustration in Figure 5 was obtained from an animal in which the food consumption prior to sacrifice was measured. It was found that the rat was eating the deficient (C-8) diet. Therefore, neither starvation nor the addition of a lipotropic agent was a factor in this instance.

(Fig. 6); in reality, they are sheets or membranes of compressed tissue. They represent the remnants of the disintegrating fatty cysts plus the original supporting structures. The sinusoids and the bile

that might account for this. The incorporation of vascular channels into membranous septa is of the utmost importance. By this means, shunts between portal vein and central vein and shunts from the

Fig. 8. The gross appearance of the liver of the rat in the various stages of fatty liver disease. The right lateral lobe of the liver, after fixation in formalin is shown in the photographs. All photographs were taken at the same magnification. As fat accumulates in the liver, enlargement occurs. Active liver cell regeneration, initially uniform throughout the liver, is an additional factor in the enlargement (Stage 3 A). In Stage 4 A the appearance of regenerative nodules is just discernible as small protruberances on the surface. Thereafter (Stages 4B and 4C) they become the dominant and conspicuous feature. The final phase is an atrophic nodular cirrhosis.

capillaries that remain are incorporated into these membranous structures by pressure. As the fat filled cysts collapse, the fat leaves either by entry into the vascular system or into the bile duct system¹⁰. The fibrous trabeculae become complex as more and more tissue is compressed into them. The larger or conducting portal veins together with their arteries and bile ducts also become included in the membranous trabeculae. Figure 7 demonstrates in a schematic fashion a mechanism

hepatic artery to the portal vein, or to the central vein can occur.

The changes in the gross appearance of the liver in Stage III is shown in Figure 8. Because there is uniform regeneration that involves each and every lobule, the gross appearance of the liver in stage III bears a close resemblance to the actively regenerating liver remnant that can be observed after a partial hepatectomy has been performed in a normal rat. In the case of the

fatty liver, each lobule already distended by fat filled cells is further increased in size by the addition of newly formed cells.

As long as the liver remains at stage III, the animal appears to remain in a satisfactory state. Uniform and regular regeneration proceeding in each and every periportal area seems to permit the liver to function adequately. Cellular disruption and new cell formation appear to be "in balance." The animal gains in body weight. Ascites or pleural effusion, common in the late stages of cirrhosis in the rat, is not seen while the liver remains at Stage III. Anemia is not a feature at this stage. Icterus is often present, as judged by the presence of bilirubin in the urine and the yellow color of the blood serum (normal rat serum is colorless). The male rat appears quite healthy despite the presence of the hypertrophic fatty cirrhosis that characterizes Stage III B. As is apparent from Figure 1, few rats died during this stage. Occasionally a rat, sacrificed as late as 225 days after the start of the experiment, exhibited no further progression of the cirrhotic process than Stage III B. This could be explained, in part at least, by coprophagia. The minute amounts of choline or precursor present in the ingested feces may furnish just enough protection to slow down but not prevent the usual sequence of events as regards cirrhosis development. The same phenomenon was observed where suboptimal amounts of choline (Diet C-8A, .05 per cent supplement) was added to the diet. This did not always prevent fat accumulation in the liver but it did retard the process considerably (Fig. 1).

Stage IV. Irregular Periportal Regeneration.—The final stage in the development of fatty cirrhosis in the rat is reached when the liver becomes nodular. The formation of regenerative nodules represents the striking and distinguishing feature of experimental cirrhosis. As this stage is reached, a few small irregularities appear on the surface of the liver (Stage IV A, Figure 8). During Stage III the surface has had a uniform appearance, a lobular pattern marked off by slight and regular pitting. The slight pit or indentation on the surface of the rat liver represents a central vein that drains the surface cells and the thin capsule. As the transition to Stage IV occurs, certain areas gradually enlarge and project further from the surface. This process is not limited to the surface

but is occurring in a haphazard fashion in all parts of the liver. This is the beginning of nodular regeneration. No longer do the newly formed cells grow in orderly or uniform fashion along predictable planes. This change in the regenerative process is shown in Figure 2 (Stage IV A). The growth of the mass of cells constituting a regenerative nodule is only partially restrained. By expansion they distort the structure of the liver pushing veins, arteries and bile ducts in various directions. Why does this occur? What mechanism operates that stimulates or permits one area of the liver to grow, seemingly at the expense of other areas? Is this focal hyperplasia due to some mechanism that induces local growth? Or do the adjacent lobules fail to grow thus allowing a dominant area to expand? Unfortunately, no satisfactory answers are available for these questions.

For purposes of classification, Stage IV has been subdivided into three phases. In Stage IV A, regenerative nodules are just discernible on gross inspection or on microscopic examination. In Stage IV B approximately one-half of the liver is made up of such nodules. Eventually, the entire liver appears to be composed of regenerative nodules; all of the original tissue is compressed between them. Cirrhosis formation may then be regarded as complete and has been designated as Stage IV C. The gross appearance (Figure 8), indicates that there is a decrease in the size of the liver in the late stages, i.e., an evolution from a hypertrophic fatty cirrhosis to an atrophic nodular cirrhosis.

The growth curves of rats that were followed throughout the natural course of this fatty liver disease indicated that a loss of body weight occurred at about the time the pattern in the liver changed from Stage III to Stage IV. The deleterious effects of the cirrhotic disorder in the rat seem somehow to be associated with the presence of regenerative nodules. In the present experiments the animals passed into stage IV between seventy-five and ninety days. The loss in weight reflected a decreased food intake as the disorder progressed. In Stage IV B and IV C pleural and peritoneal effusions, anemia and, in the males, a loss of body hair often occur. Rats do not survive long after ascites makes its appearance. They do not develop esophageal varices.

Very little is known about the origin, the struc-

Fig. 9.

Fig. 9. (*upper left*) Photomicrograph (H & E, low power) Stage IV A of fatty liver disease in the rat. In the center of the field, one of the areas of periportal regeneration is larger than the others and can be regarded as a "regenerative nodule."

Fig. 10.

Fig. 10. (*upper right*) Photomicrograph (H & E, low power) Stage IV B of fatty liver disease in the rat. Three nodules (areas of irregular periportal regeneration) are seen in the right hand side of the field. Adjacent periportal areas have not kept pace with these and are being compressed by the expansion of the nodules.

Fig. 11. (*lower right*) Photomicrograph (H & E, low power) Stage IV C of fatty liver disease in the rat. Portions of three large and several smaller nodules are shown. The original structure of the liver has been grossly distorted by the expanding nodules. The vascular components (central veins, conducting branches of the portal and hepatic veins, and hepatic artery branches) as well as the bile ducts are all compressed into the trabeculae.

Fig. 11.

ture and the functional capacity of the regenerative nodule that develops in fatty cirrhosis in the rat. Available evidence indicates that these nodules represent *irregular* periportal regeneration. The main source of blood supply appears to be the terminal branches of the portal vein. Preliminary studies bearing on this question have been made in our laboratory. Colored substances injected into the portal vein do penetrate the nodules but appear to do so with difficulty. The portal vein terminal does not uniformly occupy the center of the nodule as Figure 2 indicates. The vessel and its newly formed branches often appear to be eccentrically placed within the nodule. One must assume that the small portal vein lengthens and branches out in order to extend along with the expanding mass of cells. Regenerative nodules are comparatively large, occasionally up to 2 mm. in diameter. In such structures, several vessels of fair caliber may be seen within the substance of the nodule. When several separate vessels are seen in the transverse section of a nodule, they are

thought to represent branches of the original vessel, the latter being located at a level below the plane of the tissue cut. Further evidence that the blood supply of the regenerative nodule in these animals is predominately portal in origin is suggested by the location of injury produced by carbon tetrachloride when this is administered to rats with fatty cirrhosis¹⁴.

It is difficult to assess the contribution of hepatic arterial twigs to the regenerative nodule, for the artery is very minute in the rat and it is hard to follow the course of its branches. Although attempts have been made to trace the artery by injecting India ink, ink in gelatin and colored latex solutions in varying concentrations, adequate specimens have not been obtained. Injection studies of the hepatic vein system demonstrate clearly the effect of the regenerative nodules on these vessels. The central veins are always at the periphery of the nodules; they are incorporated in the trabeculae. The hepatic veins are flattened and compressed by the expanding regenerative

nodules in experimental cirrhosis in exactly the fashion that have been so clearly demonstrated in human cirrhosis^{7, 8}.

The biliary drainage system from the regenerative nodules is presumably by way of small ductules within the mass of cells. They are visible adjacent to the portal vessels and also as separate structures. The latter are comparable to the never-ending branching intralobular bile ductules or cholangioles seen in normal liver tissue. Biliary drainage may also occur directly through the periphery by a junction of bile capillaries to cholangioles in the fibrous walls about the nodules.

The regenerative nodule in experimental fatty cirrhosis appears to be composed of cells arranged irregularly. They are usually in the form of two-cell thick plates, although at times the original single cell plate form appears to be maintained. Hartroft has emphasized that the cells of the nodules are less fatty than their predecessors, the original liver cells. In general this is true. In our own material we have seen many instances in which the cells of the regenerative nodules do become filled with fat. In many instances fatty cysts form inside the nodule. This has been depicted in Figure 2 (Stage IV B). The collapse of peripheral intranodular cysts adds to the thickness of the trabeculae and may also contribute to septa forming within the confines of a nodule. Where several focal areas of regeneration develop in a nodule they may compress disintegrating cysts between them. The division of an original nodule by septum formation increases the complexity of the microscopic appearance. In short, one witnesses a miniature form of cirrhosis occurring within the nodules of a cirrhotic liver. Unequal regeneration or forces of expansion may cause "breaklines" or rifts within the nodule that subsequently become membranous. This explanation has been offered by Popper and Elias⁷ for the septal formation in human cirrhosis, and indicates how the liver lobule may be subdivided. It has not been thought necessary to invoke this explanation for the septa that are found in rat liver in Stage III where uniform periportal regeneration predominates. However, such an event might occur in Stage IV within the confines of the regenerative nodule. An additional factor that may add to the complexity of the late stages of experimental fatty cirrhosis is the necrosis of an entire regenerative nodule. This has been occasionally seen in liver biopsies taken during Stage IV. A

nodule may for some obscure reason become infarcted and undergo disintegration. The result will be collapse and approximation of the structures that surrounded the original nodule. Had the biopsy been secured a few days later, a "scarred area" represented only as a thicker trabeculation would have been seen. Interpretation would have been most difficult. Although this type of disintegration of nodules is rare, this can serve to emphasize some of the difficulties in interpreting the sequence of events in cirrhosis if one is limited only to autopsy material as is the case in the study of human pathology.

As individual nodules continue to grow in a seemingly unrestrained fashion, they dominate the picture in experimental cirrhosis. The original liver structure between them undergoes more and more pressure and the parenchymal cells that were initially growing in a number of periportal areas tend to disappear. The consequence is thicker and thicker trabeculae, although, in the rat, the trabeculae never become extremely thick because the capsule and the supporting framework derived from the capsule of the liver is not very substantial. It would be of interest to correlate the "fibrosis" of experimental cirrhosis in various laboratory animals to the original content of the supporting framework of the liver. In the mouse, for example, the studies of Buckley and Hartroft¹⁵ as well as those of Meader¹⁶ indicate that "cirrhosis" is not readily produced by choline deficiency. There is little or no fibrosis, although extensive fatty livers develop.

Discussion

The available information regarding nutritional requirements is now so complete that one can devise and feed laboratory animals diets deficient in various essential ingredients and thus produce certain pathologic disorders with a predictable regularity. The deliberate production of fatty liver disease in the rat by such a mechanism has been the basis for the experimental studies described in this paper. A diet deficient in methionine as a result of limiting the protein intake produces a lack of available choline. In the rat, the absence of an adequate supply of choline permits the accumulation of fat in the liver cell in pathologic amounts. This increasing accumulation of fat in the parenchymal cells leads to their destruction by cell rupture and subsequent fatty cyst formation as demonstrated by Hartroft. As a con-

sequence there is a gradual but continuous reduction in the number of functioning liver cells. One of the fundamental characteristics of the liver is the ability to regenerate in response to a decrease in the number of functioning cells. Thus the choline-deficient state fulfills very nicely the prerequisite for the study of experimental cirrhosis, —i.e., liver cells are destroyed in a slow and predictable fashion while the capacity of the liver to form new cells remains intact. The events that occur in the development of cirrhosis can be conveniently witnessed by sacrificing animals at intervals and studying the pathological changes.

The classification that we have adopted in the laboratory for grading liver specimens has been employed in this report as a background for a description of the development of cirrhosis in the course of the fatty liver disorder in the rat. As the disorder progresses, the pathologic changes at any given time are not necessarily uniform from one animal to another. An anatomic or histologic basis for a classification was necessary. It has been found useful to describe the changes in terms of "stages," and to recognize four such divisions. The response of the liver, i.e., cellular regeneration, forms the main basis for the classification that has been employed.

The transition of fatty liver to cirrhosis is dynamic, and continuous changes are occurring. Although there are no abrupt transitions, as the term stage might imply, recognizable changes do develop and persist. Thus certain histologic criteria are characteristic in each of the four stages. Stage I is recognized by the presence of fat limited to the centrilobular areas. In severe choline deficiency this stage is so transitory as to be of little importance. However, when minimal amounts of choline are present in the diet, the features of Stage I may constitute the only histologic evidence that the supply of this substance is suboptimal. Under such conditions the liver may remain in this stage for months. The continued presence of *small* amounts of fat in the liver does not lead to structural changes. However, when the deficiency of choline is severe, the liver cells quickly become filled with fat; a stage is reached in which every parenchymal cell is involved. This has been termed Stage II. It is also a very transitory stage. The immediate response to such a situation—one in which the total mass of *functioning* liver cells is reduced—is the formation of new cells. Thus the liver quickly passes into a third and more pro-

TABLE II. STAGES IN FATTY LIVER DISEASE IN THE RAT IN SEVERE CHOLINE DEFICIENCY

I Centrilobular Fat	3-10 days*
II Entire Liver Fatty	10-15 days
III Uniform Periportal Regeneration	
A. Fibrosis Absent	15-30 days
B. Fibrosis Present (hypertrophic fatty cirrhosis)	30-75 days
IV Irregular Periportal Regeneration	
A. Regenerative Nodules (just detectable)	75-90 days
B. Regenerative Nodules (involve one half of liver)	90-120 days
C. Regenerative Nodules (involve entire liver)—(atrophic fatty cirrhosis)	120-180 days

*Time periods are applicable only to the conditions of the present study; the character of the diet, the sex and strain of rat and the age of the animal when the hypolipotropic diet is started, all influence the rate of progress.

tracted phase in which cellular regeneration is a prominent feature.

Stage III is characterized by uniform regeneration in the periportal areas of the liver. The areas about the *terminal* portal veins represent unique features in the rat as demonstrated by the studies of Hartroft. An early aspect of Stage III is the occurrence of regeneration before fibrous trabeculae are visible in microscopic sections (Stage III A). Very soon, however, the disintegrating fatty cysts and the adjacent supporting structures are compressed into fibrous trabeculae that link central veins and conducting portal veins. This compression of tissues produced by the forces exerted by myriads of areas of active liver cell regeneration about periportal areas determines the pattern of the fibrous trabeculae that characterizes Stage III B, a hypertrophic fatty cirrhosis.

The final phase in the transition of the fatty liver to cirrhosis is reached when *uniform* periportal regeneration changes to *irregular* periportal regeneration (Stage IV A). This is recognized by the appearance of the "regenerative nodule" which is believed to be the characteristic morphologic feature of irregular periportal regeneration. The full development of experimental cirrhosis is attained when the regenerative nodules completely dominate the gross and microscopic picture. By their expansion, the nodules compress all of the original liver tissue into membranes of varying thickness and composition. Ultimately, the liver is reduced to an atrophic nodular cirrhosis. The site of origin and the subsequent growth of the regenerative nodule is believed to be the most distinctive and important feature in the development in this form of experimental cirrhosis. Unfortunately, there is as yet very little

information concerning the fundamental nature of this phenomenon.

No direct application of a study of fatty cirrhosis in an animal may be made to the problem of human cirrhosis. The present studies have dealt with a highly artificial and in many respects simple experimental model, a rat fed a purified diet under strict laboratory conditions. Human liver disease, and particularly cirrhosis, is an extremely complicated disorder. The factors or agents that cause cirrhosis in patients are many and varied. If fat accumulation plays any role in the pathogenesis of human cirrhosis, it does so only in those instances where faulty nutrition is a prominent feature. In our own clinical material this is virtually limited to patients with the disease, alcoholism. There are many other types of human cirrhosis that bear no relationship whatsoever to faulty nutrition or to fatty liver disease. And even where fatty liver disease is a feature, as in cirrhosis in the chronic alcoholic patient, the pathogenesis of the disorder is far more complex than in the simple experimental model just described. A few generalizations gained from a study of the course of the disorder in one species may be applicable to the study of a more complicated disorder in another species. Beyond that, however, no application should be attempted.

In closing, I should like to pay tribute to the contributions of Miss Bernadine Wittenburg to these investigations. From 1949 until her death early in 1955, Miss Wittenburg was a research associate on our staff. In her role as a laboratory supervisor she served loyally and devotedly and was responsible for the preparation of all of the histologic specimens employed in the early studies.

FRACTURE HEALING SPEEDED

Antituberculosis drugs appeared to be responsible for the more rapid healing of fractures in seven tuberculosis patients treated at the Central Washington Tuberculosis Hospital, Selah, Washington. Drs. Albert R. Allen and A. W. Stevenson presented their findings at the recent meeting of the American Medical Association.

Four patients with hip fractures ranging in age from sixty-two to eighty-six years had full weight-bearing in

an average of fifty-five days (forty-two to seventy-five days). Eleven nontuberculous patients with hip fractures who ranged in age from forty-seven to eighty-nine years healed sufficiently for weight-bearing in an average of ninety-four days (forty-four to 145 days). Only two of this group were ambulatory as early as the patients receiving antituberculosis drugs; *i.e.*, within seventy-five days.—*Medical Science*, 2:15 (July 10) 1957.

Studies on Congenital Goiter and Hypothyroidism in an Adult Male Patient

NORMAN H. ENGBRING, M.D.
WILLIAM W. ENGSTROM, M.D.
Milwaukee, Wisconsin

AMONG individuals with hypothyroidism, and more specifically, among those with cretinism, there is a peculiar group known as "sporadic goitrous cretins." This group is distinct from the more frequently observed type of *sporadic* cretin that is athyreotic. It is also distinct from the more frequently observed type of *goitrous* cretin that is found in endemic areas of iodine deficiency. The so-called "goitrous cretin" is characterized by the presence of a goiter and hypothyroidism but without evidence of iodine deficiency or a goitrogen-containing diet as a cause of the disturbance. The hypothyroidism appears to be the result of a congenital defect in the synthesis of thyroid hormone.

In the normal person (Fig. 1), circulating iodide is trapped by the thyroid gland, oxidized to iodine and immediately bound to the amino acid, tyrosine, to form moniodotyrosine and diiodotyrosine. Further synthesis by coupling results in the formation of thyroxine which may then be released into the blood stream or be stored in the gland in conjugated form as thyroglobulin to be released at a later time. A defect in the enzymatic processes involved in any one of the steps might result in lack of thyroxine formation and consequently hypothyroidism.

In the "sporadic goitrous cretin," the defect in synthesis of hormone may be of two types: (1) a defect in oxidation of iodide to iodine may result in failure of organic binding of iodine, in which case it can be flushed from the gland by thiocyanate ion, and (2) a defect in coupling of moniodotyrosine and diiodotyrosine to form thyroxine (or a possible defect in deshalogenation

of moniodotyrosine and diiodotyrosine) in which case these compounds might be found in large amounts in the thyroid and also in the blood. The patient studied by us appears to represent an example of the latter defect. Similar cases have been studied by others.^{1,2,3,4}

Case Report

The patient was a white male asylum inmate, aged forty-eight, who was seen at the General Hospital over a period of several years.

Fig. 1. Diagrammatic illustration of the formation of thyroid hormone. Sites of blocks by certain compounds or as congenital defects are indicated.

From the Department of Medicine, Marquette University School of Medicine, and the Milwaukee County General Hospital, Milwaukee, Wisconsin.
Supported in part by a grant from the Wisconsin Chapter of the American Heart Association and by a grant from the United States Public Health Service (A-1200 (C3)).
Presented in part at the Regional Meeting of the American College of Physicians, Minneapolis, Minnesota, November, 1956.

Chronological history revealed a relatively normal early development, sitting at eight months, dentition at eight months, and walking at fourteen months. As a child, the patient was mentally slow. He frequently had

nea. The patient appeared hypothyroid, and his basal metabolic rate was minus 16 per cent. Chest x-ray revealed a widened supracardiac shadow presumably due to thyroid enlargement.

Fig. 2. Photograph of the patient demonstrating "cretinoid" appearance.

difficulty in swallowing, and food had to be removed from his mouth. He developed difficulty in breathing and was seen by the family physician who advised removal of a "gland." At fourteen years of age, the patient was admitted to a local hospital for removal of what was thought to be a persistent thymus. No masses were noted in the neck. At surgery, a large intrathoracic thyroid was removed. Pathologic diagnosis was "possible fetal adenoma."

After the operation, the patient was noticed to be more sluggish, mentally and physically. His voice was husky. He was treated for a time with desiccated thyroid, but this medication was discontinued when he became hyperactive and irritable. The patient did poorly in school, advancing to the eighth grade at sixteen years.

At seventeen years of age, he was admitted to an institution for mentally deficient children. While there, he was treated for "possible cretinism" with some improvement, being discharged at twenty-one years as "not feeble minded."

Thereafter, he worked as a newsboy until he was twenty-six, when he was committed to a mental institution because of mental deficiency. At the time of commitment, a goiter was noted in the neck. The patient stated that this had developed within a year after the first thyroidectomy. The mass was described as being the size of an orange, multinodular and soft. He complained of occasional pressure symptoms, notably dysp-

Figs. 3 and 4. Photographs of the patient illustrating anterior and lateral views of the head and neck. Note facial characteristics and anterior cervical mass.

A second thyroidectomy was performed at twenty-seven years of age. The pathological report noted numerous nodules, 1 to 3 cm. in diameter, in a gland measuring 3 x 5 x 9 cm. Microscopic sections showed a varied pattern with areas of microfollicular adenomas and other areas consisting chiefly of colloid. Malignant changes were suspected.

The patient was next seen at the General Hospital at forty-six years of age, when the thyroid status was more thoroughly investigated. Physical findings (Fig. 2) included a cretinoid appearance, puffy eyelids, thick tongue, short broad hands and feet, dry skin and myotonic reflexes. The ratio of upper to lower body segments was 1.1 to 1. A firm 4 cm. mass was noted in the anterior cervical area (Fig. 3 and 4). No bruit was heard. The patient stated that this mass had recurred within a short time after the second thyroidectomy.

Pertinent laboratory data included a basal metabolic rate of minus 36 per cent, serum cholesterol of 528 mg. per cent, and serum-protein-bound iodine of 1.8 micrograms per cent. Therapy with desiccated thyroid was begun but was discontinued within a month because of aggravation of angina pectoris which had existed in mild degree for about two years.

During the following year and a half, the anginal attacks became more frequent and more severe. The electrocardiogram showed evidence of left ventricular hypertrophy, and x-ray examination of the chest revealed displacement of the trachea to the right with evidence of tracheal compression.

Procedures and Results

In order to elucidate the nature of this patient's hypothyroidism, several additional procedures were undertaken. Twenty-four hours after the oral administration of a tracer dose of I-131, the uptake

over the thyroid was 21.8 per cent, a normal value (Fig. 5). Administration of 2 gm. of potassium thiocyanate orally caused no release of radioactivity from the thyroid area, indicating that the

Discussion

Normally, no diiodotyrosine can be identified in serum, although small amounts have been recovered after large therapeutic doses of radioac-

Fig. 5. Radioiodine uptake by the thyroid gland illustrating lack of effect of 2 grams of potassium thiocyanate given orally.

trapped iodine was organically bound.

In order to identify the compounds produced by the patient's thyroid, blood samples were obtained at twenty-four, forty-eight and seventy-two hours after a 0.5 millicurie dose of radioactive iodine. Each sample of serum was acidified to pH 3.5 with sulfuric acid and extracted three times with double volumes of butanol. After evaporation under reduced pressure at 65° C., the residue was applied to Whatman No. 3 MM filter paper strips and developed with descending phase chromatography using a tertiary and amyl-ammonia solvent. The paper was then cut into one centimeter strips and radioactivity determined in a scintillation well-counter. Areas of radioactivity were identified by spots produced by known compounds including diiodotyrosine, inorganic iodide, thyroxine and triiodothyronine. Significant quantities of diiodotyrosine were found within twenty-four hours, with a marked decrease in amount after three days and a relative increase in the amount of thyroxine (Fig. 6).

The administration of ten units of thyroid stimulating hormone (TSH) caused no rise in the protein-bound iodine of the serum after six and twenty-four hours.

tive iodine.⁵ It might be assumed that in this case a block in thyroxine synthesis leading to the hypothyroid state caused an increased stimulation of the thyroid with marked overproduction of diiodotyrosine. This metabolically inert compound subsequently spilled over into the bloodstream. The increased size of the gland, the rapid regrowth after surgical removal, and the histologic appearance also suggest marked stimulation of the gland. It is apparent that some thyroxine was being formed by the gland, although in small amounts and at a slow rate, suggesting that the defect in synthesis was not complete. Stanbury^{6,7} has suggested that another congenital defect may be in the thyroidal deiodination of monoiodotyrosine and diiodotyrosine. These compounds would then be lost from the thyroid and subsequently from the body to such an extent that thyroxine formation is impaired.

Furthermore, the fact that the administration of TSH did not cause a rise in the iodinated compounds of the serum, might be expected if the patient's endogenous TSH level was already high or if TSH was incapable of causing release of stored diiodotyrosine from the thyroid gland.

Therapy of this patient was precluded by the

fact that even one-quarter grain of desiccated thyroid administered daily caused an increase in the number of anginal attacks. In other individuals with this type of thyroid defect, therapy with thy-

Summary

A case of congenital goiter and hypothyroidism in an adult male patient has been presented. The nature of the thyroïdal defect was elucidated by

Fig. 6. Radioactivity on chromatograms of extracted serum taken at twenty-four, forty-eight and seventy-two hours after an oral dose of I-131, using tertiary amyl-ammonia solvent. Note early appearance of diiodotyrosine (T2) and slower appearance of thyroxine (T4).

roid hormone should produce euthyroidism as well as regression of the size of the goiter, presumably by TSH suppression.

Hypothyroidism of this nature, due to a congenital defect in synthesis of thyroid hormone, undoubtedly is an unusual occurrence. However, the very common so-called "simple goiter" and adenomatous goiters may, in some cases at least, represent variants of this disorder.

identification of diiodotyrosine in the bloodstream following administration of radioactive iodine. The nature of the defect in this case appeared to be in the coupling of iodotyrosines to form thyroxine.

Pectus Excavatum

GILBERT S. CAMPBELL, M.D.
MARVIN L. GLIEDMAN, M.D.
SAMUEL HOROWITZ, M.D.
RICHARD L. VARCO, M.D.
Minneapolis, Minnesota

FUNNEL chest, pectus excavatum, trichter-brust, chonechondrosternon, foveated chest are all synonymous terms identifying the same congenital malformation. This defect exists as a rather conical-shaped deformity involving predominantly the gladiolar segment of the sternum. There is a posterior displacement of the gladiolus which starts at the manubrial junction and continues dorsally toward an apex that may even be behind the ventral plane of the vertebral bodies. From this depth the xiphoid component of the sternum usually angles inferiorly and anteriorly. All degrees of this malformation exist, from the minimal indentation to a prominent pit capable of holding several hundred cubic centimeters of fluid. The third through the eighth costal cartilages are correspondingly involved by this sternal dislocation and hence assume abnormal curvatures as they course posteriorly to join with the displaced gladiolus.

Although this condition was recognized by Bauhinus in 1594,¹ and had been described carefully under the name of trichterbrust by W. Ebstein in 1882,² clinical interest in this condition was scant and sporadic until the comprehensive review in 1939 by Ochsner and DeBakey.³ Probably an even more important factor in arousing the surgeon's attention was the presentation by Brown⁴ in that same year of the anatomic aspects of and technical principles involved in the management of this problem. The structural basis for this defect, he contends, are abnormalities of diaphragmatic development and the substernal ligamentous attachments. Obvious by-products of his theories have been his recommendations for the surgical relief by elevation of the depressed bony structures. Furthermore, he has examined the natural history of the process and called attention to its often progressive state from infancy through childhood and into adult life. In addition, he has recognized and catalogued those disabling pulmonary, circulatory, and/or psychologic consequences of severe pectus excavatum.

Concerning the incidence of this malformation, Nowak⁵ reported having encountered but twelve cases in 30,000 children. In his study of the families of these children there were a total of 106 individuals, and 38 per cent (24 males, 17 females) suffered from this congenital anomaly. Predisposing factors, other than this familial tendency, are difficult to identify. Although implicated by some authors, the evidence is scant that either rickets or Harrison's groove are causally related to the funnel chest deformity. Most students of this problem, moreover, have written with obvious uncertainty as to just which mechanisms were mainly involved in the genesis of this defect. The theories proposed have been numerous and at times verged on the fantastic (abnormal intra-uterine pressures) when compared with Brown's anatomic studies.

Of the physiologic disabilities, a significant contraction in the maximum ventilatory capacity has been more frequently encountered by most investigators than a correspondingly severe circulatory impairment. The former derangement arises from several causes. There is uniformly impairment of the free diaphragmatic action. Too, in a typical case the sternal motion is paradoxical during respiration. There is a posterior displacement at the apex of the funnel on inspiration followed by an outward movement on expiration. This abnormal response may be related to any shortening present in the central tendon of the diaphragm, arising as a consequence of congenital inadequacy of the septum transversum component of the total diaphragmatic partition, and is the anatomic basis for the funnel chest deformity according to Brown.⁴ This insufficiency of the central tendon is alleged by him to pull in the sternum at the gladiolar xiphoid junction. He also affirms that frequently there is, in association with this reduction in the amount of tissue available to the tendinous expansion of the diaphragm, an associated hypertrophy or thickening of the substernal ligament.

Whereas abnormalities of cardiac function are less frequently encountered than those interfering with pulmonary action, when present they can be

From the Department of Surgery, University of Minnesota Medical School, Minneapolis, Minnesota.

disabling.⁶ Circulatory dysfunction is more commonly provoked by bouts of paroxysmal tachycardia. Such an episode can be quite incapacitating. With an episode of tachycardia the patient

Fig. 1. Trichterbrust (from *Deutsches Arch. f. Klin. Med.*, 1882).

often will note weakness, dyspnea, palpitation and excessive sweating. In pectus excavatum patients, it is not uncommon to hear abnormal murmurs, which disappear after restoration of a more normal contour to the thoracic cage. Too, associated congenital cardiac anomalies may be somewhat masked and their true identity confused by the consequences of the heart's displacement.

Typically, the youngster handicapped by a moderately severe funnel chest is hollow chested and stoop-shouldered, walks with an exaggerated slouch and exhibits a pot-bellied profile. To meet these changes the dorsal spine is bent forward and is often scoliotic. Figure 1 is a drawing of a patient with trichterbrust which appeared in Ebstein's 1882 article.² Ordinarily, with such a physique, the individual is poorly developed physically and often has a contracted exercise tolerance both from

the encroachment on pulmonary ventilation and from any associated circulatory dysfunction. It is readily appreciated that these persons can become, by virtue of their pitiful posture and other handicaps, the object of derisive and cruel teasing. The psychologic impact on those tender and easily disturbed emotions of childhood can be readily surmised. To disrobe and thereby uncover the object of this ridicule, the funnel chest, whether at swimming or in the gymnasium, is to invite the scornful comments of the more normal and healthy. One of our adolescent patients was an inveterate truant until this disfigurement had been satisfactorily corrected.

A final analysis of the precise degree of physical disability suffered by the patient on the basis of pulmonary dysfunction and circulatory difficulties is usually difficult to make, and the emotional problems are even less susceptible of accurate calibration. With regard to the former evaluation, the maximum breathing capacity in a patient with a marked degree of funnel chest not infrequently is depressed to less than 50 per cent of normal. This determination represents a far more accurate test than a simple measurement of the patient's vital capacity. The latter determination, unless the dimension of time is included, loses its reliability as an index of pulmonary function.

As suggested earlier, the presence of bizarre cardiac murmurs and an unusual cardiac silhouette are common findings in a person with trichterbrust. This combination enhances the problems of an accurate cardiac evaluation. The association of some type of congenital heart disease adds further to these diagnostic limitations. It appears reasonable to propose, therefore, that, whenever the funnel chest deformity is linked with any cardiac disability, an additional justification for the operative correction of the malformation exists.

The Operative Management

The principles proposed by Brown⁴ and the details added by Ravitch⁷ provide us with an operative technique which is quite effective for all infants and children. With minor modifications it probably works as well as any other procedure in adults to achieve as much correction as one can anticipate in these less promising cases. Some have termed this method a radical approach to the problem. Whereas it has been suggested that simple freeing of the xiphogladiolar region from the

adherent fibrous tissue beneath it may well suffice for some infants, the subsequent evaluation of these results does not uniformly support that premise when it is applied to all.

To date twenty children and adults have been operated upon at the University of Minnesota Hospitals since mid-1952. Their ages ranged from one to forty-eight years. In one child a pulmonary valvar stenosis was corrected at the same operation. From this total experience we are inclined to the idea that corrective surgery should be carried out in any child where there exists a clear-cut indication of pulmonary impairment, cardiac dysfunction and/or a distressing cosmetic deformity. As additional endorsement of this viewpoint, we have noted that the infants have been amazingly tolerant of the required surgical manipulations. Furthermore, the eventual restoration of a near normal thoracic contour and, hence, the best cosmetic result has been achieved in young children. For nearly all individuals, however, it should be possible to improve substantially the most disabling degrees of deformity. The limited successes encountered at times in the adult group speak in favor of more frequent recourse to surgery in childhood, because a cure is virtually assurable after a well done operation carried out during this age period. In each case it should be realized that besides the benefits from improved pulmonary function and the relief from those consequences of cardiac displacement, as well as avoiding or reducing the degree of psychic trauma, are those advantages from the prophylactic avoidance of dorsal kypho-scoliotic changes and their consequent postural abnormalities.

Customarily, we have exposed the entire sternum from the manubrium to the tip of the xiphoid through a midline incision and the pectoralis fascia then reflected bilaterally. After the xiphoid process has been freed from its gladiolar attachment, it can be dissected from the surrounding fibrous elements in the linea alba and excised. All costal cartilaginous elements participating in the pectus excavatum deformity have been carefully exposed through appropriate radial incisions extending from the sternum over the osseous costal elements. We have attempted to remove each cartilage subperichondrially. These perichondrial sheaths if carefully preserved permit regeneration of a stable thoracic cage and fix the sternum in its new anterior position. To bring the sternum up from the depths, a wedge osteotomy is made in the

anterior table and all retrosternal sites of fixation released. This V-type excision of the anterior table is made transversely just at the point where the gladiolus dips abnormally away from the manubrium and towards the dorsal spine. Having freed by sharp and blunt dissection the substernal ligamentous and diaphragmatic attachments, the posterior table of the sternum can be readily raised and infracted. Finally, the lateral restraints of the sternum have been divided sufficiently to permit its over-correction to a tilted-up position. It is maintained here with two or three sutures of heavy silk or stainless steel wire which pierce the outer table only. This entire dissection can usually be made without entering either pleural space. After a thorough cleansing of the wound with a warm saline solution and securing precise hemostasis, the pectoral fascia can be closed in side-to-side manner from above down. This is usually possible to about midsternum or to that level where the insertion of more sutures appears to depress the sternal tip to a significant degree. After approximating the subcutaneous fascia and the skin, a laterally built-up dressing is applied without tension to protect against undue displacement. No external or internal struts, other than those cited, have been used in most instances in this series. However, in two adults, gentle traction was applied to a fine polyethylene tube reinforced with a stainless steel wire passing beneath the sternum. Polyethylene insulated steel wire was connected via rubber tubing to two to three pounds overhead traction. Elastic rubber tubing permits motion during ventilation, and simple changes in direction of traction enable the patient to sit or to remain supine. Traction is maintained for two and one-half to three weeks in order to hold the sternum in a slightly overcorrected position. Paradoxical motion has not been a feature of the convalescence, and even the tiniest children have done well. There has been no serious postoperative complication and no death in this series.

Conclusion

The operative management of funnel chest represents an effective means of modifying this congenital anomaly. Undoubtedly, considerable reservation about recommending this procedure will linger in the minds of most parents and many physicians unfamiliar with the accomplishments possible through contemporary surgical methods.

Elective Induction of Labor

F. L. SCHADE, M.D.

R. P. HALLIN, M.D.

Worthington, Minnesota

THE subject of elective induction of labor has been a source of controversy among obstetricians for decades. The traditional conservative viewpoint that good obstetrical care demanded allowing patients to go into spontaneous labor unless interruption was indicated by some obstetrical or medical complication has doubtless enjoyed the majority position. Feeling in some circles has approached almost evangelistic fervor for this attitude, and sometimes it has been considered even a moral issue. In 1939, the Committee on Clinical Affairs of the Central Association of Obstetricians and Gynecologists sent a questionnaire on induction of labor to its members and was able to publish a report on 125 replies covering 13,891 deliveries.¹ An attempt was made to induce labor in 1,669 of the cases (12.2 per cent). The procedure failed in 11 per cent of these inductions. The report showed wide variation in the frequency with which induction was used. Twenty-six of the obstetricians who answered the questionnaire reported an average incidence of 24.1 per cent, while in the remaining group the corresponding figure was 6.6 per cent.

In our practice, we have become very liberal in our interpretation of indications for elective induction. Perhaps it is important and of considerable interest to discuss some of the factors which have influenced us in this attitude.

Until 1951, our small city of 8,000 plus population and its surrounding area in the southwestern part of Minnesota was served by very inadequate hospital facilities. The equipment was good, but the physical plant was most unsatisfactory by present-day standards. The building was a small frame church remodeled for use as doctors offices, then later remodeled for use as a hospital. There was no labor room, but there was one small delivery room. Patients labored in their hospital beds, if they were fortunate. If, as was all too often the case, beds were not available, and if more than one patient was in labor, one might find

laboring women on cots, litters, or roll-aways in the hall, and on at least one occasion on the davenport in the small lobby. This institution was serving a small but busy clinic composed of eight physicians, as well as three outside physicians. There were thirty-three beds, and since there was little possibility for hospitalizing patients by department, obstetrical cases competed for beds with medicine, surgery, ear, nose and throat, and pediatrics. In addition, many of our patients lived on farms a considerable distance from the hospital, and the threat of snow storms blocking their access to town was a source of much concern to both the patient and to her physician. In this inadequate thirty-three-bed hospital, we averaged around 415 deliveries a year.

In order to alleviate this problem, we began to select cases for elective induction of labor if certain criteria were present. Selection of patients must be rigid when labor is electively induced. Cephalopelvic disproportion must not exist. The fetus should be mature and the presenting part engaged or dipping well into the pelvis. The cervix must be ripe—that is, soft, partially effaced, and dilated at least 1 or 2 cm.

We found a surprisingly large number of patients fulfilling these criteria, even two weeks before the estimated date of confinement calculated from the menstrual history. When these criteria were reached in an individual patient, the patient was offered induction of labor. Originally, our method of induction consisted of the following routine. The patient was admitted to the hospital in the morning without having breakfast. She was given an enema and 6 to 12 grains of ergot. This was followed by stripping the membranes and/or sterile amniotomy. We have since discontinued the use of ergot. Since discontinuing ergot, our patients for induction of labor receive $\frac{1}{4}$ minim of pitocin, intramuscularly, upon admission as a test dose for unusual sensitivity to that drug. If labor does not ensue shortly after amniotomy, we now use dilute intravenous pitocin.

In general, physicians tend to follow those

¹Presented before the Minnesota Society of Obstetrics and Gynecology, Duluth, Minnesota, April 27, 1957.

Spontaneous	228	252	267	222	240	1209	69.00

procedures which, in their experience, lead to satisfactory results. This outlined procedure seemed to be giving good results, and we saw no reason to modify our position when we moved into our new modern eighty-five-bed hospital in May, 1951, unless a statistical analysis of our cases proved our procedure incompatible with the practice of good obstetrics. It is altogether possible for a physician to become over-enthusiastic about a method of treatment which seems to give good results. In order to remove our experience from the realm of speculation, we have analyzed the results of our obstetrical experience for the years 1949 through 1953.

These statistics reflect our experience. They were computed for self-evaluation and are presented here only as a report.

Analysis

This report is based on a statistical analysis of 2,162 deliveries occurring in the Worthington Municipal Hospital, for the five-year period, 1949 through 1953.

Of the 2,162 deliveries, forty-nine (2.26 per cent) were by cesarean section. There were sixteen sets of twins. Of those deliveries by the vaginal route, 518 (24 per cent) were induced.

From Table II, it can be noted that of the 2,162 deliveries, 1,761 were done by our clinic group. There were forty-two cesarean sections, giving an incidence of 2.38 per cent. In 510 cases (29 per cent), delivery was accomplished by induction of labor. This figure includes both elective inductions and those induced for medical

TABLE IV. AVERAGE LENGTH OF LABOR

	Average	Others	Clinic Spontaneous	Clinic Induced
Multipara	6' 29"	8' 32"	7' 33"	3' 37"
Primipara	9' 36"	10'	10' 45"	5' 45"

and obstetrical reasons. When these figures are broken down on a yearly basis, we find our inductions of labor increased from 22 per cent in 1949 to 35 per cent in 1953.

It is of interest to note the indications for cesarean section. (Table III).

The effect of induction on the length of labor, both on multiparous and primiparous women is shown in Table IV. By way of explanation, the term "others" refers to six physicians, not members of our clinic, practicing obstetrics in the Worthington Municipal Hospital. The average length of labor for the multipara was six hours and twenty-nine minutes. Those delivered by other physicians averaged eight hours and thirty-two minutes. Multipara with spontaneous delivery were delivered in seven hours and thirty-three minutes, while those who were induced averaged three hours and thirty-seven minutes.

The average length of labor for the primipara was nine hours and thirty-six minutes. Those primipara women delivered by other physicians averaged ten hours. Our primiparas with spontaneous delivery were delivered in ten hours and forty-five minutes, while those with induced delivery averaged five hours and forty-five minutes.

Those cases in which the onset of labor was too vague and the length of labor could not be accurately determined were omitted in this portion of the report. In spite of these omissions, the length of labor was reduced by approximately one half by the induction of labor. There were no maternal deaths. There were no failures in our inductions. On two occasions, the intravenous

TABLE VI. INDUCTION NEONATAL DEATHS

1. Atalectasis—four days over estimated date of confinement—face presentation—full term by x-ray. (4 pounds 4½ ounces)
2. Eclampsia with convulsions. (3 pounds 7 ounces)
3. Atalectasis—thrombophlebitis with last pregnancy—bilateral vein stripping. (5 pounds 6½ ounces)
4. Erythroblastosis—hydrops—(induced at 36 weeks)—(7 pounds 5 ounces)

pitocin was repeated the next day and labor started.

We were interested in the effect upon the baby. In Table V, an analysis of these cases compares very favorably in both neonatal deaths and stillbirths with those figures per 1,000 births as furnished by the Minnesota State Board of Health. Our neonatal death rate was about the same in both induced and spontaneous deliveries, but we had only about one-quarter as many stillbirths in those patients induced as in those allowed to go spontaneously into labor. It can be noted that our neonatal deaths per 1,000 deliveries and our stillbirths per 1,000 deliveries were about one-half of the average figures furnished by the Minnesota State Board of Health. It is possible our good figures may be attributable to our elective induction of labor in that postmaturity of the infant is lessened. In 1951, Clifford Reid and Worcester reported that postmaturity, defined on the basis of gestational age, ranked second only to prematurity as a cause of fetal and neonatal mortality.² There are two progressive physiological changes *in utero* that are believed to account for the clinical findings in postmaturity—the disappearance of vernix caseosa of the skin and the aging process in the placenta with the resultant fall in oxygen content in the blood in the umbilical vein at the forty-third week to less than 8 volumes per cent. It is pointed out that since the fetus requires 6 to 7 volumes per cent, by the forty-third week, it is able to obtain just enough oxygen from the blood for its needs in the resting state. Walker's³ physiological studies lend definite support to the conception that risk of injury to the fetus in-

TABLE VII. MATERNAL MORBIDITY

	Total	Number	Per Cent
Spontaneous	1595	67	4.20
Induction	518	27	5.21

creases with prolongation of pregnancy beyond the optimal time for delivery.

Table VI lists the four cases of neonatal deaths. Two of them (Cases 2 and 4) did not occur in what we might call elective inductions. They were induced for obstetrical reasons, as listed.

There seemed to be little difference in maternal morbidity, whether patients were induced or allowed to deliver spontaneously.

Summary

1. A sketchy historical background is given to justify our use of electively inducing labor.
2. Selection of patients must be rigid, and the following criteria present:
 - (a) Cephalopelvic disproportion should not exist.
 - (b) The fetus should be mature and the presenting part engaged or dipping well into the pelvis.
 - (c) The cervix should be ripe—that is, soft, partially effaced, and dilated at least 1 to 2 cm.
3. Our method of induction is presented.
4. A statistical analysis of 2,162 deliveries occurring in our rural hospital, for the five-year period, 1949 through 1953, is presented.
5. The incidence of our induction of labor increased from 22 per cent in 1949 to 35 per cent in 1953.
6. The length of labor in both primiparas and multiparas was reduced about 50 per cent by induction of labor.
7. Our neonatal death rate was about the

Chylothorax Complicating Cardiac Bypass

and Studies in Thoracic Ductography

JOSEPH J. GARAMELLA, M.D.
Minneapolis, Minnesota

THE thoracic duct has long remained a hidden and unfamiliar structure. The medical student has only been cognizant of its existence. Today it assumes a seat of greatly increased importance because of the greater frequency of surgical procedures which invade the territory of the thoracic duct in the posterior mediastinum.

The collected cases of traumatic chylothorax are listed in Table I. Since Lampson's successful ligation, thoracic duct ligation for the treatment of chylothorax has been performed at least 40 times without mortality.

The purpose of this presentation is twofold: first, to report a case of traumatic chylothorax,

TABLE I. COLLECTED CASES OF TRAUMATIC CHYLOTHORAX

Ligation thoracic duct

Although first discovered in a horse by Eustachius,¹ a Roman anatomist in 1565, in dogs and other species by Asellius¹ in 1622, and in man by Veslinghius² in 1634, the thoracic duct may be said to have yielded as a surgical organ a decade ago when this structure was first successfully ligated by Lampson³ for the treatment of chylothorax. Peet and Campbell,⁴ in 1943, had ligated the thoracic duct for chylothorax, but their patient succumbed suddenly following the ligation, the cause of death being undetermined.

In the era prior to Lampson's successful ligation, the thoracic duct was shrouded with mystery. The impunity with which the thoracic duct can be ligated was not only unrecognized but, in addition, ligation was strongly forbidden.^{5,6,7}

Presented before the regional meeting of the American Trudeau Society, Saint Paul, Minnesota, January 25, 1957.

complicating closure of an interventricular septal defect, and secondly, to submit a number of thoracic ductograms performed in cadavers which may serve to orient and alert the surgeon to the variations of thoracic duct anatomy.

Case Report

A white woman, aged thirty-six, was hospitalized with disabling cardiorespiratory complaints. Prior to admission she was bedridden. A diagnostic survey including cardiac catheterization gave definite evidence of an interventricular septal defect and pulmonic stenosis. On November 9, 1956, cardiac bypass was performed, employing the extracorporeal heart-lung apparatus as described by De Wall and associates.⁸ The heart was electively arrested with potassium citrate.⁹ Right ventriculotomy was performed, and an interventricular septal defect approximately 3 cm. in diameter was found in the membranous portion of the interventricular septum. This was closed with a running 2-0 silk suture. The pulmonic valve orifice admitted the small finger but

the commissures of the cusps were fused. These were readily split by the index finger. The duration of cardiac bypass was twenty-one minutes. The duration of cardiac arrest was thirteen minutes. The heart resumed normal rhythm after coronary flow was restored.

Fig. 1. Pertinent features of the postoperative period are charted, correlating symptomatology, fluid accumulation and chest catheter drainage. Ligation of the thoracic duct on the nineteenth day postoperatively controlled the chylothorax.

The arterial pH before perfusion was 7.56 and after perfusion was 7.53. The plasma hemoglobin before perfusion was 16 mg. per cent and following perfusion was 90 mg. per cent. The preoperative weight was 118 pounds; the postoperative weight was 120 pounds. The systolic blood pressure during the period of perfusion ranged between 70 and 90 mm. of mercury and postoperatively was 90 mm. of mercury. In the recovery room, the patient was conscious and responsive, and her general condition was considered excellent.

Postoperative Course.—The pertinent features of the postoperative course, including respiratory changes and chest catheter drainage, are summarized in Figure 1. Significant x-ray changes in the chest are shown in Figures 2-6. The diagnosis of chylothorax was established on the tenth postoperative day following thoracentesis. The characteristics of the fluid obtained from the chest were as follows: (1) milky appearance with an upper white layer, (2) specific gravity—1016, (3) no odor, (4) sudan fat stain—microscopic fat was demonstrable after ether extraction, (5) direct smear—no bacteria; many mononuclear cells were identified, (6) protein—3.2 grams per cent, (7) culture—no growth after two days, (8) differential study of cells—100 per cent lymphocytes. A coaltar derivative was given to the patient orally in a 75 mgm. capsule, and within forty minutes red coloration of the chest catheter drainage was noted. The chest catheter drainage in a period of six hours was 600 cc., a rate of 100 cc. per hour.

Repeated thoracentesis and chest catheter drainage

were performed on this critically ill patient and were supplemented with parenteral fluid replacement (proteins, water and electrolytes), between the tenth and nineteenth days. Because of the repeated and continued accumulation of chylous fluid, ligation of the thoracic duct was elected.

Operative Description.—On November 28, 1956, with the patient in the three-quarter prone position, thoracotomy was performed through the bed of the ninth rib. There was considerable inflammatory reaction with complete symphysis of the right pleural space. Fibrinous material covered the visceral and parietal pleurae. The lung was not congested nor edematous and there was no palpable pneumonitis. The hilar lymph nodes were markedly enlarged and boggy. Forty minutes prior to the dissection, 25 mgm. of Evans blue dye were injected subcutaneously in the thigh as recommended by Merrill.¹⁰ The thoracic duct and three parallel channels were very well demonstrated between the azygos vein and aorta by the method. A thoracic ductogram was attempted but was inconclusive. The thoracic duct and the parallel collecting structures were ligated. Appropriate chest catheters were inserted and the chest was closed in layers. The chest catheter drainage was principally serosanguinous (Fig. 1). X-ray examination of the chest on the fourth day following thoracic duct ligation showed improvement (Fig. 6a). The catheters were removed five days following duct ligation. The patient was no longer dyspneic. There was progressive weight loss noted with marked diuresis. The patient's weight at the time of thoracic duct ligation was 121½ pounds and at discharge thirty-two days later her weight was 107 pounds. The relation of the weight loss to the duct ligation was not clear. On the twenty-ninth postoperative day, the patient was breathing more comfortably without oxygen. The heart rate was 95/minute. There was no venous distention nor edema. Following thoracic duct ligation, there was an abrupt decline in appetite and food intake and her abdomen seemed distended, suggesting ascites. The liver was enlarged 2½ fingerbreadths below the right costal margin and the spleen 2 fingerbreadths below the left costal margin. The relation of these visceral enlargements to blockage of lymph following duct ligation was considered. On the thirtieth postoperative day, the patient continued to show marked clinical improvement. She was ambulatory without dyspnea. She was cheerful and alert and talked about going home. The liver and spleen were still palpably enlarged. There was some tenderness over the liver. Her weight was 106¾ pounds. On the thirty-first postoperative day, the patient was anxious to go home. There had been a reversal of the AG ratio: total protein 7.4 mgm. per cent with albumin 3.1 mgm. per cent and globulin 4.3 mgm. per cent. On the thirty-second postoperative day, the patient was discharged.

Three Month Follow-up.—The patient had resumed activities including dancing and ice skating.

Thoracic Ductograms

Thoracic ductograms were performed in thirty-five cadavers over a five-year period. The tho-

Figs. 2a,b, 3a,b, 4a,b, 5a,b, and 6a,b. Sequential chest x-rays may be correlated with the clinical features presented in Figure 1 and in the text.

thoracic duct was isolated in most instances above the diaphragm between the azygos vein and aorta. Cannulation was followed by injection of radiopaque media (70 per cent diodrast) without controlled pressures. In some instances, the left jugular, subclavian and innominate veins were obstructed by clamps. Following the injection of dye, x-rays were taken. The most interesting ductograms are presented in Figures 7-18.

Discussion

General considerations of the anatomy, embryology and physiology of the thoracic duct as well as the clinical aspects of chylothorax have been reported and can be reviewed by the interested reader. The case herein reported presents the characteristic features of traumatic chylothorax, namely, the element of trauma, probably sus-

tained during the cannulation of the left subclavian artery, followed by a latent period, respiratory embarrassment and shock-like state relieved by thoracentesis with recurrence of symptoms following the reaccumulation of chyle in the chest. Ligation of the thoracic duct appears to have been a life-saving procedure in this instance. Evans blue dye was helpful in outlining the thoracic duct and its collaterals.

Thoracic ductography has been previously reported by Lowman,¹¹ Stranahan,¹² and Celis.¹³ The dye contrast studies presented here emphasize the frequent variations in thoracic duct patterns, departures not found in standard anatomy textbooks. Collateralization as shown in Figure 14 offers one basis for the impunity with which the thoracic duct can be ligated as was demonstrated in the experimental work of Lee¹⁴ and Blalock.¹⁵

Fig. 7. Thoracic ductogram. The thoracic duct has been injected just above the diaphragm. The course of the duct is as usually described commencing to the right of the mid-portion of the vertebral column and crossing to the left of the spine at the level of the sixth thoracic vertebra, then extending cephalad to the neck forming the arch of the thoracic duct. Multiple clamps on the jugular, subclavian and innominate veins prevent entry of dye in the venous system. Note the second smaller terminal ending of the duct.

Fig. 8. Thoracic ductogram. The thoracic duct has a more tortuous course. The several points of constriction with dilatation proximal and distal to the constriction are sites of valves. Note the two terminal endings of the duct.

Fig. 9. Thoracic ductogram. The mid-portion of the thoracic duct shows a racemose pattern. The duct has been ruptured in the upper third, showing extravasation of dye. Multiple terminal endings are present in the neck.

Fig. 10. Thoracic ductogram. A plexiform pattern is present in the middle third of the thoracic duct. From the upper third, a tributary is noted extending to and partially filling the right jugulosubclavian junction. In spite of multiple clamping of the left jugular, subclavian and innominate veins, extravasation of dye is present in the left hemithorax.

Fig. 11. Thoracic ductogram. The lymphatic collecting system in the thorax consists of a plexus of large lymphatics rather than a single trunk as in Figure 7. Two large branches from the upper third of the system extend to the right jugulosubclavian junction. Multiple possible sites of injury in the mediastinum are apparent.

Fig. 12. Thoracic ductogram. A plexiform pattern is present in the middle part of the thoracic duct. Valves, present at the junction of major collecting trunks as the intercostals with the thoracic duct, usually prevent retrograde filling. Note that two left intercostal trunks have been partially filled in this study. Some extravasation of dye has occurred from the plexiform network.

Fig. 13. Thoracic ductogram. The thoracic duct in the mid-portion is formed by a large plexiform pattern from which a single trunk arises and extends into the left neck, forming the arch of the thoracic duct emptying into the left subclavian vein. The left subclavian and jugular veins are outlined with the left innominate vein.

Fig. 14. Thoracic ductogram. This injection was performed in a patient who died of metastatic malignancy. A radical neck dissection had been done on the left side several years previously. Note the extensive collateralization of lymphatics in the upper mediastinum and lower neck.

Fig. 15. Thoracic ductogram. Autopsy findings in this patient included an aneurysm of the aortic arch. The upper portion of the thoracic duct has been displaced to the right by the tumor mass.

Fig. 16. Thoracic ductogram. Simultaneous cephalad and caudad injection of the thoracic duct was done. The cysterna chyli is filled. The mid-portion of the thoracic duct shows the insula of Haller.

Fig. 17. Thoracic ductogram. Caudal injection of the thoracic duct at the level of the diaphragm was performed. A parallel collateral duct is seen in the lower segment. The cysternal area is obscured by extravasation of dye due to rupture of the duct system. A large left lumbar trunk is apparent.

Fig. 18. Thoracic ductogram. Retrograde injection of the lower thoracic duct was performed. A true cysterna chyli is absent. A diffuse plexiform pattern is present instead.

Summary

1. A case of chylothorax complicating closure of an interventricular septal defect was successfully treated by ligation of the thoracic duct.
2. Thoracic ductograms were presented demonstrating variants of the anatomy of the lymphatic system.

STOP AND STRETCH

It is a good idea to stretch your legs or take a short walk every hour or so during a long automobile trip or on a train or plane, advises Dr. John G. Bielawski, medical director of the Michigan Heart Association. Blood can "pool" in the legs during such inactivity and blood

clots may form, break loose and shut off circulation to the lung. Automobile drivers are most vulnerable because they sit still and don't move their legs even as much as passengers, he said.—*Today's Health*, August, 1957.

The Psychiatrist Looks at the Acutely Disturbed Patient

HOWARD P. ROME, M.D.
Rochester, Minnesota

"An empirick often times, and a silly chirurgeon, doth more strange cures than a rational physician . . . because the patient puts his confidence in him, which Avicenna prefers before art, precept, and all remedies whatsoever. . . . He doth the best cures, according to Hippocrates, in whom most trust."

—ROBERT BURTON: *Anatomy of Melancholy*

THE DAY-TO-DAY practice of medicine takes for granted the relationship between the physician and his patient. Much has been said and written about this relationship as a theoretic force but, as a tangible vicissitude of the lives of physicians and patients, its meaning and significance have been subordinated to other considerations that often have far less therapeutic value. Since the fact, as well as the management, of the disturbed patient is so often a reflection of this relationship, it appears worth while to examine it as a potent therapeutic force.

There is a commonly held stereotype that caricatures both the doctor and his patient. Even though it is a gross misrepresentation, like all caricatures it mirrors its subject by an exaggeration of characteristic features. This canard pictures the physician as a benevolently paternal figure, possessed of endless patience, tolerance and wisdom. Not only is he able to ferret out the complexities of a baffling differential diagnosis, but also he can select unerringly the best of modern medicine's newest discoveries with which to cure his patient. On the other hand, the patient is equally misrepresented as infinitely co-operative, passively receptive, and even stoically compliant and grateful.

If you will grant that even rarely this stiff, overdrawn, unnatural portrait is fobbed off as a reasonable facsimile of a flesh-and-blood doctor and his patient, you may follow with me the consequences of this misleading picture and see in par-

ticular the denouement witnessed in the form of an acutely disturbed patient and an equally disturbed situation clamoring for succor.

Myths, like proverbial cats, have many lives. While they appear to die when drowned by wave after wave of scientific knowledge, they also seem to possess the qualities of poltergeists, for they appear in the most unlikely situations, purring a kind of defiance to logic, reason and common sense. The explosion of a mythically idyllic, one-sided doctor-patient relationship is no exception. Such a disruption is followed by the inevitable emergency, frequently interpreted as a need for decisive action, new faces, sterner measures, stronger medicines, accusations, counterassertions and the like.

The art of medicine includes more than the perspicacious ability to select from a therapeutic armamentarium the appropriate drugs, advice or procedures necessary to do something actively to combat disease. The remedy of disease obviously implies an understanding of its natural history.

In the days when humors were rampant, the therapeutic procedures of choice were clysters, venesection and trephination. It appeared an altogether natural corollary to the theory of morbid fluids that purgation be an effective antidote. The disturbed patient was not exempt from the application of comparable metaphysical judgments, for his treatment included auto-da-fé, exorcism and incarceration. Since to be disturbed or psychotic was to be possessed, it seemed to be a soundly based therapeutic philosophy to give the devil his due.

In that era, nature was either benign or malignant. If the former state prevailed, it would be revealed in all its glory as a "natural motion" to conformity in speech, thought and behavior. By the same token, if malign forces lurked in human form, they too could be exposed for what they were by the hallmarks of berserk actions, meaningless gibberish and moonstruck thinking. There

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

was only need to apply the test and not only would the diagnosis be made but also the remedy determined. Things were clear-cut, cause and effect were defined, and the application of principles and practices was consistent.

In a scientific era, similar things are often similarly clear, even though the reasoning is by a different logic and hence different causes are postulated. The clarity of one's vision depends on the glass through which things are seen. The Dark Ages were not exclusive in the use of dark glass. In all charity, then, the problem of the disturbed patient and his appropriate treatment must be examined in the light of the therapeutic philosophy held by his peers and superiors.

The cultural change that has removed us from the *auto-da-fé* has charged the physician with secular powers rivaling those once held solely by his ecclesiastic brother. The disturbed patient by common consent is now a medical responsibility. Unfortunately, this allocation of responsibility does not always carry with it commensurate authority. For authority must be recognized, appreciated and deferred to in order to be effective. The imperative to do something, make a decision, make a disposition or act, almost always undermines the physician's position to the point where he is neither a free agent to act as he deems wise nor capable of unalloyed judgment. Most often, his task is to secure peace and tranquility at almost any price. It is at this juncture in the practice of his art that the physician must examine the role in which he is cast by others, as well as the one he assumes.

At this crucial juncture, he has two alternatives. First, he can appear as he is, an identified outsider with some skill in these matters but nevertheless one who appreciates the fact that he, like the others who preceded him, is suspect until he can know and become known to the patient. Once he is trusted sufficiently, he then can offer the expertness that his presence alleges. The other alternative is deceptively appealing, for it appears to lead from strength. In this guise, the physician is an officer of the peace, an authority with unlimited power whose task it is to take over an anarchic situation and restore order by fiat. Time obviously is of the utmost importance, for once the physician is committed to a strategy, the tactical and logistic execution of it spells the difference between success and failure.

This indeed is the age of the tranquilizers. The public fervor with which they have been heralded betokens a crusade for solace in our times that has many serious implications. This is also the age of adjustment, of positive thinking, and of other-directedness versus conformity, an age in which the premium on deviation is extremely high. Consequently, the temptation to do the expedient is most alluring. It is in consonance with these tendencies that medical practitioners in some instances are beguiled to stoop to conquer. The boon of solace comes at a price; even though the reckoning is delayed, the subordination of ends to means is costly deficit-financing.

The disturbed patient always has been a quixotic figure, roaring and tilting at windmills and fooling no one but himself. In times when conformity is deemed a virtue, he is especially disruptive of the status quo and almost invites being unhorsed. Since physicians are not exempt from public opinion and pressure, they frequently rationalize such treatment by the snare that quixotic extravagances are more than well-regulated traffic will bear. In the mind of the physician, who is fortified by a glance at the stereotype of benevolent paternalism, strong-arm tactics are quickly converted to what now appears as a worthy crusade to restore tranquility.

There are three aspects of the problem of the care of the disturbed patient that should be considered in the light of the preceding comments. The first has to do with the patient and what made him disturbed. The second has to do with the physician. The third has to do with the interplay between them and what it signifies about each.

A disturbed patient manifestly does not fit the stereotyped role expected of him. He is neither co-operative nor grateful; indeed, potentially at least, he is prone to fight off every effort to help him. This is why he is said to be disturbed. Patients are people and are especially sensitive to slights, neglect, deprivation, rejection and abuse. Promises either made or implied and not fulfilled yield a harvest of frustration and resentment. The capacity to restrain an expression of these feelings varies with the age of the patient, as well as the severity and chronicity of the disease. A uniquely personal equation also exists; in different people and at different times in the life of the same person, the tolerance for conflict in one or another of its forms varies. Thus, many

factors determine the level of the water on the one hand and the height of the dam on the other. The critical factor that must be kept in mind is that innate perversity is the least likely reason for the disturbance. Good and sufficient reasons usually are present in the patient's history to account for these manifestations; if these reasons are sought for, they can be uncovered.

The most unlikely explanation for most instances of disturbed behavior is the one most frequently given. The presence of so-called toxic-infectious-metabolic factors often is alleged to be the basic cause, even though there never has been substantial evidence to document this. At various times in the history of medicine, various synonyms have been used to emphasize concepts like humors and toxic-infectious-metabolic causes of disturbed behavior of manifold sorts. The reasoning seems to be that, since these words sound impressively poisonous, they will convince even the skeptical that they must be harmful and hence of etiologic significance. It apparently makes little difference whether evidence exists for their postulated presence. In an age of science, it appears more valid to indict a chemical, a virus, a metabolic anomaly, a neurophysiologic cell assembly or a recessive gene than it does to blame purely psychologic or psychosocial symbolism, for the latter seems particularly insubstantial. Thus, instead of following our Dark Age forebears in the practice of condemning the whole patient, we usually select one or another of his systems, secretions, excretions or physiologic compositions and hold it to be the key cause of his disturbance. The remedial measures that are applied follow appropriately from this.

The disturbed patient is never less than the whole consequence of all that has happened to him physiologically and psychologically. Until the physician becomes equally familiar with all the dimensions of the problem, he is treating only part of it.

In the attempt to balance the equation of disease: treatment, one aspect sometimes is overlooked, namely the physician's unwitting contribution. His professionalism, acquired slowly during the course of a long apprenticeship, can be a barrier to the vitally important communication that is the essence of all human relationships. Exchange and interchange are the heart of communication. The process of sharing anxiety with an understanding person will slake it. On the other

hand, professionalism is an unnatural formality, a deterrent to free communication, a psychologic obstacle that effectively insulates those human qualities of honest interest and frank sincerity that must be offered to sick patients if they are to withstand the corrosive undermining caused by pain and anxiety. The presentation of simple descriptive preliminary explanations of what is going to be done and to happen is as important as superb mechanical technique, diagnostic erudition or even pharmacologic wizardry. Familiarity inevitably breeds contempt for what is thought to be obvious and commonplace, and it is a difficult chore for sophisticated professionals to remember constantly that most patients are naïve in matters of sickness and therapeutic procedures. Left to their own unguided devices, most patients substitute fantasy for fact, and the illogical conclusions that sometimes result in aberrant behavior are less the fault of the patient than they are errors of omission of critical information on the part of his attendants, who should know better.

Professionalism leads to a kind of aloofness and austerity that expects automatic deference to obviously more competent judgment and acceptance of preformed decisions. It tends to disapprove sharing the bits of information on which these judgments are based. In this light, the "good" patient is the one who passively accepts and graciously defers to professional competence obviously superior to his own.

When expectations exceed actualities, bitterness is bound to result, regardless of the reasons for the discrepancy between desire and attainment. The low tolerance of the sick for frustration makes irritability, petulance and emotional lability characteristic features of all disease and injury. Unless the origin of this susceptibility, as well as its unreasonable disproportion, is appreciated as being as much a part of illness as is fever or leukocytosis or pain, a punitive attitude of reprisal in retaliation for the patient's apparent ingratitude or impertinence is likely to precipitate an acute disruption of the relationship of the patient with his physician. The additional loss of security that this calamity imposes on a patient with already enfeebled defenses is often enough to provoke a regressive crisis of major significance. This is the disturbed patient.

Towers of strength are both reassuring and formidable. The physician and his professional en-

ourage occupy this strategically ambivalent position in the feelings of an anxious patient. Subtleties are looked for and sensed as auguries of a future that bodes uncertainty. Misreading and misinterpretation are common and the sense of desperation that follows may provoke disturbance in all realms of the patient's function. As Francis Peabody advised the physician a generation ago, the secret in the care of a patient is in caring for him.

Finally, there is further significance in the physician-patient relationship. All trauma and stress are relative. The experiential past of every person is stored with an accumulation of vulnerabilities, many of which are unconscious in the sense of being immediately unavailable to logic and reason. Their affects, however, are potential triggers for the release of feeling or behavior or thoughts that belong to bygone times. These have a peculiar algebraic quality and, consequently, the clinical expression that appears as an acute disturbance cannot always be ascribed solely to the

immediate train of events that preceded it. Events are linked in the chain of time by their symbolic connections, many of which are not at all clear to either patient or physician. A frightening childhood experience of loneliness or a long-forgotten but still smoldering adolescent anxiety about fancied injury can wax into florid signs and symptoms if the proper provocation allows it to be exacerbated.

Thus, the treatment of the medical emergency associated with a disturbed patient must be tailor-made to fit the particular patient in the particular situation at the particular time. This is why there is no good substitute for the presence of an interested physician.

"...For if he discover and declare unaided by the side of the patient the present, the past and the future and fill in gaps in the account given by the sick, he will be more believed to understand the case, so that men will confidently entrust themselves to him for treatment."

PECTUS EXCAVATUM

(Continued from Page 621)

However, when serious or alarming degrees of pectus excavatum are encountered, it is important to recollect that the individual can suffer from progressive degrees of pulmonary incapacitation, cardiac dysfunction and emotional trauma. The latter is quite as capable of warping the child's behavior as the deformity is his physique. Furthermore, to achieve the best results in all of these regards, but with particular emphasis on the last consideration, it is wise to consider having the individual operated upon early in life.

Differential Points in the Problem of Headache

E. DOUGLAS ROOKE, M.D.
Rochester, Minnesota

THIS discussion of some of the differential points in the problem of headache will be limited to certain aspects of some varieties, including the vasodilating headache, tension headaches, the exertional type and nocturnal headaches.

Vasodilating Headaches

The term "vasodilating headache" designates a group of headaches in which vasodilatation apparently is the main mechanism that produces pain. The most obvious characteristic of a vasodilating headache is the throbbing type of pain, with a rhythm that corresponds approximately to the pulse rate. This rhythmic qualification is made because some patients describe their headache as "throbbing" and yet demonstrate a beat with their hand that appears to have no relationship whatever to cardiac rhythm. Such headaches should be suspected of having some other cause.

However, not all vasodilating headaches throb. Another characteristic that suggests a vasodilating mechanism is rapid onset or cessation of the pain. The term "rapid" does not mean "abrupt," as with a neuralgic pain; rather, the pain builds up to a maximum in a few minutes and may recede in a similar way, although not necessarily so. Other features, such as dilatation and tenderness of superficial arteries, reddening of the face (especially when unilateral), mucosal swelling and excessive secretions in the eye or nasal passages on the side of the pain, may suggest a vasodilating mechanism. The two most obvious examples of this type of headache are migraine and so-called histaminic cephalalgia. (The latter will be considered under the heading of "nocturnal headache.") In addition, there are a number of peculiar syndromes of atypical facial pain to which many names have been applied; some of these, at least, appear to have obscure vasodilating features.

For the most part, the vessels involved in vasodilating headache are extracranial; digital com-

pression of the external carotid or superficial temporal vessels often demonstrates brief relief of pain. The participation by intracranial vessels, however, is not uncommon and indeed must be assumed in explaining most of the characteristic migrainous auras. It is thought that most migrainous headaches have an early vasospastic phase that, in some patients, may bring on the various types of auras, followed soon by the pain-producing vasodilating phase.

The typical migrainous headache needs no special comment, as it presents few diagnostic difficulties. Along with various tension components, it makes up the bulk of the headaches seen in general practice. It might be worth while, however, to mention some of the uncommon characteristics of migraine and some of the conditions that may masquerade in migrainous trappings.

The auras of migraine may present a diagnostic problem, especially in those rare instances when they occur without the headache; at times, even when the headache follows in its usual sequence, the serious implications of the earlier symptoms overshadow the headache in the mind of the patient or physician, and the significance of the sequence is missed.

Such a patient may report the sudden onset of numbness and tingling on one side of the body involving the face, arm or leg, or all three. The discomfort may last for a few minutes or a half hour. When this symptom occurs alone, its significance may be obscure. In most instances, at least some of such repetitious episodes will be followed by a typical throbbing headache, nausea and vomiting. However, specific inquiry may be necessary at times to bring out these latter events. If it then can be established that a family history of migraine exists and that some attacks have involved the other side of the body, the migrainous nature of the illness may be suspected.

The prime differential diagnosis in older patients with such attacks of episodic numbness involving different parts of the body is that of insufficiency of the basilar artery; a few patients

From the Section of Neurology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is part of the Graduate School of the University of Minnesota.

with the syndrome of such insufficiency may experience headache during these episodes. However, the headache of basilar disease is usually less severe than is the average migrainous headache. Also, the basilar syndrome, although far from common, will be seen much more frequently than will migrainous phenomena when the symptoms first appear in patients more than fifty years of age. Other characteristic signs and symptoms of dysfunction of the brain stem will help distinguish the basilar syndrome from the innocuous auras of migraine.

The episodes of hemiparesis that may occur during the vasospastic auras of migraine are the motor counterpart of the afore-mentioned sensory episodes. These are more likely to persist into and beyond the headache than are the sensory phenomena. Such motor difficulties are less common than the sensory episodes, but the same associated phenomena give the clue to their migrainous nature.

Visual auras are more widely recognized because they are more frequent. These may be negative scotomas or positive scintillating teichopsia (fortification phenomena) or both; homonymous hemianopsia, although less common, also may occur. As with the motor and other sensory phenomena, the migrainous nature of these disturbances may be missed if the subsequent headache is absent, mild or minimized by the patient.

The most important single feature of these various premonitory vasospastic phenomena is that they precede the headache and usually disappear before the headache comes on. This is not invariably the case, particularly with the rare motor disturbances, but whenever the auras do carry over into the headache, migraine should not be accepted as the explanation without careful consideration of such intracranial lesions as aneurysm, arteriovenous anomalies and brain tumor.

A slight degree of ptosis or even a well-developed Horner syndrome, including ptosis, miosis and enophthalmos, is seen occasionally in attacks of migraine. However, headache that is followed by any considerable degree of ptosis should not be lightly accepted as a migrainous phenomenon.

The so-called ophthalmoplegic migraine is an extension of this problem. Although Wolff¹ considered that some cases may be explained on the basis of compression of the third, fourth or sixth cranial nerves by the swollen and edematous walls

of intracranial arteries, one should remember the possibility of other less benign explanations. Patients who exhibit severe paralysis of the extraocular muscles on the same side as their headache during the latter part of a severe "migraine" may well prove to have a progressive intracranial lesion. If the headache in these patients always recurs on the same side of the head, one should be particularly skeptical of the diagnosis of migraine. Some patients apparently do have their migraine unilaterally and always on the same side throughout their lifetime, but this is rare. In most instances, a few attacks of migraine will involve the opposite side of the head or the pain will be diffuse. Many patients have their migrainous headaches bilaterally, and the old idea that a bilateral headache is not migraine is no longer tenable.

Tension Headache

Tension headache to some physicians means any headache suspected of being psychogenic in origin, including conversion and somatization headaches. Others use the term to indicate the supposed mechanism of pain in certain patients whose basic difficulty appears to be psychoneurotic and in whom muscle tension is a common factor. Although this chronic sustained headache is usually symptomatic of an associated psychoneurosis, a small controversial group of closely related conditions exists, including fibrositic headache, myalgias and fatigue headache, that are not easy to separate from the larger psychoneurotic group. These related conditions produce pain that is less relentless than the usual tension headache, and they respond to the use of salicylates and physical therapy in varying degrees. In general, the term "tension headache" is not meant to include these "organic" conditions but is used to describe this particular variety of psychoneurotic headache. Even in this type, the mechanism of the pain is apparently muscle tension, and this in turn is considered to be an expression of the underlying psychoneurosis.

The usual story is that of a chronic, low-grade, steady, unremitting, bilateral, frontocervical or cervico-occipital headache lasting for days, weeks or months in a patient who presents other indications of psychoneurosis, such as anxiety, insomnia and morning fatigue. Bending, coughing, sneezing, heavy lifting and movements of the neck usually do not affect this type of headache to any appreci-

able degree. Tenderness on palpation of the scalp and neck muscles usually is present. Before one accepts the diagnosis of tension headache, the possibility of the previously mentioned myalgias and fibrositic conditions should be considered, and various local cervico-occipital mechanical and structural lesions should be excluded as carefully as possible.

There is a tendency to apply the label of "tension" to any chronic cervico-occipital headache that occurs in the absence of demonstrable organic disease, especially in a patient who has other symptoms of anxiety and tension. Certain circumstances exist, however, that should cast suspicion on this diagnosis of tension headache. Such suspicion is aroused (1) when the pain is unilateral, (2) when it responds favorably to simple analgesics such as the salicylates or to a brief course of physical therapy, (3) when it is definitely modified by position and activity, as when relief is obtained by resting the head against a chair or wall and when it is increased by straining at stool or cough, (4) when it is described in simple, accurate and unembellished terms, (5) when, despite chronicity, certain periods of clear-cut relief occur and (6) when the story suggests a real element of progression.

The characteristics just mentioned may be found in the cervico-occipital pain associated with cervical spondylosis and spondylitis, or in such conditions as whiplash injury to the neck, protrusion of cervical intervertebral disks, intraspinal tumors and tumors at the foramen magnum, bone tumors in the neck (primary or secondary), congenital malformations in the upper part of the spinal column and essential hypertension.

The important point is that physicians should be reluctant to ascribe this type of pain to tension headache just because objective changes cannot be demonstrated. The diagnosis also should be based on a symptom complex consistent with that diagnosis and a personality problem compatible with psychoneurosis. In the great majority of cases, such chronic cervico-occipital pain will be a tension headache, but the other possible causes just enumerated must be kept in mind.

Exertional Headache

Symonds² has written recently about exertional, or effort, headache and called the entity "cough headache."

The clinical picture in this type of headache

has been regarded for many years as pathognomonic of a serious intracranial lesion, particularly brain tumor, and it still should be so regarded if serious diagnostic errors are to be avoided. However, it is now apparent that a group of patients does exist in whom extensive investigation fails to reveal any intracranial lesion to explain the symptoms and whose future course may well prove to be favorable.

I do not know of any way to distinguish on the basis of the symptoms alone between benign exertional headache and headache that is symptomatic of an intracranial expanding lesion. All such headaches must be considered as potentially dangerous. However, when the results of a neurologic examination are negative, when electroencephalographic and contrast studies reveal no abnormality, or when such a headache has been present for many months or years without progression, it is comforting to realize that such an entity as exertional headache apparently does exist.

The characteristics of exertional headache are as follows. The headache is brought on from complete comfort within a few moments, if not immediately, by any exertional maneuver, such as coughing, sneezing, straining at stool, bending or lifting. It may last from a minute or so to an hour, but it is more often of short duration. It is to be distinguished from the common condition in which a headache already present is made worse by those same exertional activities.

Symonds² reported on seventeen patients followed for one to twelve years without the appearance of any neurosurgical disease. At the Mayo Clinic, my associates and I have been following a growing group of such patients since 1952. In a recent unpublished survey, we had replies from twenty-eight patients whose headaches had been present for two to twenty-five years. Their ages ranged from fifteen to seventy years, but this type of headache appears to be more common after the age of fifty years. Many (60 per cent) of our patients have had electroencephalograms, air studies or angiograms. Of the entire group followed thus far, only two patients later have shown some demonstrable intracranial lesion to explain their symptoms.

The importance of this group of patients is mainly for the reassurance its existence gives the physician when results of extensive investigation have been negative. It apparently is reasonably well established that certain exertional headaches

may be benign; the chance of spontaneous disappearance of symptoms is apparently about 20 per cent, and the condition in two out of three patients in our series has tended to improve. It is obvious, of course, that any worsening of such a headache, any change in its character or the development of other significant symptoms requires complete re-evaluation of the problem.

Nocturnal Headache

Nocturnal headache refers to one that, although it may occur on various occasions during the day, tends to be more common and more troublesome during the hours of sleep. This circumstance in itself is disturbing. In addition, some of these headaches may indicate serious disease. A considerable variety of conditions may feature the symptom of nocturnal headache. Four of these will be considered in this presentation.

Histaminic Cephalalgia.—This special variety of vasodilating headache was first given the name of "histaminic cephalalgia" by Horton,³ in 1941. There appears to be reason to question the specific etiologic relationship of histamine to this clinical syndrome, but a typical case is so characteristic that some specific designation is desirable. The term "Horton's syndrome" has been selected by some authors, whereas others use such terms as "cluster headache" or "seasonal headache"; one author,⁴ in his efforts to escape any etiologic implications, has designated the condition as "a particular variety of headache." Whatever it is called, the typical syndrome is striking.

This type of headache tends to appear during the fourth and fifth decades of life. Unlike migraine, the syndrome is more common in men than in women. Although headaches of this sort may appear during the day, the classic one is nocturnal, usually developing to a maximum within a few minutes or being maximal when the patient awakens. As a rule, the pain is unilateral and often is about or deep behind one eye, but may extend from there along the side of the head into the face or down into the shoulder. The flushing of the face, "running" of the nose and stuffiness of the homolateral nostril attest to the vascular nature of the disorder but are not necessarily present. The pain of this headache is of the greatest severity. It may or may not be throbbing. Patients do not remain in bed with this headache; rather, they get up and pace the room. The su-

perficial arteries over the involved temple usually are distended, swollen and tender, but this need not be so. When only deeper branches of the external carotid artery are involved, there may be little to see except the patient's very evident distress. The distinctive features of this type of headache are the sudden onset of pain, its great severity, the brief duration (twenty to sixty minutes) and the fairly rapid subsidence; superficial tenderness and reddening of the skin or mucosal edema usually is present but not invariably so.

The erroneous diagnosis of tic douloureux, or trigeminal neuralgia, is made in a considerable number of these patients. Some even have had section of the fifth cranial nerve or occipital nerves or both. Tic douloureux and histaminic cephalalgia are both manifested by extremely severe pains about the head and face of sudden onset and sudden cessation. Pronounced tearing of the eyes may be present in both conditions, but lacrimation is more likely to be bilateral in tic douloureux and unilateral in Horton's syndrome. By the time a patient with tic douloureux has pressed a hot or cold cloth to his eye for a few minutes, and some do this despite the presence of trigger points, that region may become red and injected in appearance and may be so described by the patient in response to questions, without any elaboration on how it achieved that appearance. Both types of pain tend to recur in attacks lasting days to weeks. These similarities may be confusing indeed at first glance, but there are even more differences, if they are sought out.

The most obvious difference is in the pain itself. The pain in tic douloureux has a flashing, lightning-like, often repetitively stabbing quality, and it persists only for seconds or rarely more than a minute. This pain may be repeated quickly, so that the patient may speak of a pain lasting twenty minutes or more; however, close questioning discloses that this "pain" consists of a series of briefer pains. The pain of tic douloureux is brought on by various activities, such as talking, chewing and touching the face at certain trigger points. Not every pain can be so explained, but the patient knows that during an attack he can seldom take liberties with such activities without paying the penalty. These trigger points are not present in Horton's syndrome, a fact that can be established when the patient is examined. The distribution of pain is a point of distinction; the pain in tic douloureux is confined to the distribu-

tion of one or more branches of the trigeminal nerve, whereas the pain of the vasodilating headache may be felt throughout the distribution of the external carotid artery. The age of the patient also may be helpful. Tic douloureux occasionally is seen in patients less than forty years of age, but most patients are at least fifty years of age before it appears. Horton's syndrome has been known to appear for the first time in patients more than fifty years of age, but most of them are less than fifty.

Headache Associated with Brain Tumor.—Nocturnal headache, particularly of recent development, makes most physicians consider the possibility that the patient has a brain tumor or some other expanding intracranial lesion.

There is no typical pain that is characteristic of brain tumor. The life history of such a headache often gives a better clue than does the type of pain. The pain may be a dull ache that is more bothersome than incapacitating, or it may be explosive in severity, as when the dynamics of the intracranial fluid are interfered with. As a rule, however, it is not an outstandingly severe pain and it often responds well to compounds of acetylsalicylic acid (aspirin). It may or may not be associated with nausea or vomiting or both. The well-known projectile type of vomiting is not often present except in children.

As already noted, the life history or behavior pattern in a series of headaches may suggest the presence of an intracranial expanding lesion. When the headache varies unpredictably in its severity and when, over a period of weeks or months, it gradually becomes more frequent and more severe, an expanding lesion should be seriously considered. When such a headache is worsened by straining at stool, lifting and bending, or jarring or sudden turning of the head, particularly when it is brought on from complete comfort by such exertional activities, there is real need to exclude progressive intracranial disease.

Headache Associated with Hypertension.—It is not known why certain patients with hypertension have headache while others with an equal or greater degree of hypertension do not. This type of headache is likely to be dull, diffuse and throbbing. It is often occipital, and it may be unilateral. It tends to awaken the patient in the early morning hours, or it may be regularly present at the morning awakening. The headache often improves

when the patient assumes an upright position, and use of aspirin often helps. The pattern is repetitive or periodic but not progressive as a rule.

The mere presence of hypertension is not enough to identify this headache, since increased intracranial pressure tends to cause secondary hypertension. The absence of the characteristic funduscopic changes usually seen in significant hypertension should suggest caution in ascribing any headache to the hypertensive group of diseases, regardless of the blood pressure. Under such circumstances, intracranial expanding lesions should be considered as a possibility. Another condition that may produce headache and hypertension with normal-looking fundi is pheochromocytoma.

Headache Associated with Temporal Arteritis.—This type of headache is not truly nocturnal; it tends to persist all day as well, but patients complain that it is especially troublesome at night. The headache of cranial or temporal arteritis occurs almost exclusively in patients more than sixty years of age. It is usually bilateral, with associated tenderness of the scalp, but it may be unilateral or hemitemporal. The pain is usually constant, steady and moderately severe, and it is little influenced by movement of the head, position or cough. In many patients, the enlarged, firm, tortuous, temporal arteries stand out, with reddening of the adjacent skin and extreme tenderness to touch. In others, visible vascular changes are absent. These headaches ordinarily are resistant to the milder forms of analgesics. Considerable constitutional reaction, such as irritability, undue fatigue and pallor, often is present. When cranial arteritis is thought of, the laboratory can give real help in that the erythrocytic sedimentation rate is almost invariably 100 mm. or more during the first hour (Westergren method), and anemia often is present. Biopsy of an involved segment of an artery is the preferred method of establishing the diagnosis.

Cranial arteritis is essentially a self-limited disease, but it has one extremely serious complication, namely blindness, which occurs in one or both eyes in 30 to 40 per cent of these patients unless adequate treatment with corticosteroids is instituted early. It is because of this visual damage, usually caused by ischemic optic neuritis, that early recognition and treatment of cranial arteritis are important. Unfortunately, the headache is not a

(Continued on Page 657)

Treatment of Some Types of Headache

JOSEPH G. RUSHTON, M.D.
Rochester, Minnesota

IN ORDER to be concise and informative this discussion will be limited to the more common types of headache (migraine and tension headache) and to two types (histaminic cephalalgia and cranial arteritis) that are uncommon but urgently require prompt and careful treatment. Physicians are constantly reminded that a carefully taken history is the proper beginning for the solution of any medical problem. A repetition of this truism would be tedious were it not for the fact that the treatment of any headache is apt to be poor or to fail if the taking of a detailed history is neglected. The frequency and duration of headaches, as well as the time of day or night when they start, will, to a great extent, determine the type of medicine and the mode of administration to be used. The person who becomes nauseated and vomits early in the course of a headache will require rectal or parenteral administration of medicine. A careful inquiry concerning medicines previously employed will allow the physician to avoid the use of remedies that the patient has found ineffective or harmful, or may lead him to recognize that such remedies were ineffective because improperly used. A patient who has in the past displayed an idiosyncrasy to a drug will be less than grateful if the physician makes the mistake of giving such a drug as a result of inadequate history taking.

Vasodilating Headaches

A discussion of the treatment of vasodilating headaches is simplified if they are divided into those of long duration (migraine) and those of short duration (histaminic cephalalgia).

Vasodilating Headache of Long Duration.—A classic attack of migraine usually evolves in three stages. The first is that of vasoconstriction and the second is that of vasodilation. If this second stage is prolonged it merges into the third stage in which the arterial walls become edematous.

From the Section of Neurology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is part of the Graduate School of the University of Minnesota.

The stage of vasoconstriction may be recognized by the occurrence of paresthesia, focal weakness, aphasia or, most commonly, visual disturbances. Ordinarily, this stage requires no treatment. When it assumes major proportions because of long duration or the alarm experienced by the patient, treatment may be needed. A variety of vasodilating agents may be used. The simplest is nitroglycerine in the form of a 1/100 grain tablet placed between the tongue. Amyl nitrite is a potent vasodilator but its effect is too transitory, its use attended with too much drama, and its residual odor too reminiscent of unclean feet to be a good choice. If a vasodilating drug is used, it may be expected to relieve the stage of vasoconstriction but will not necessarily abort the subsequent headache.

The stage of vasodilation is treated by the use of vasoconstricting drugs. Of these drugs ergotamine tartrate, with or without caffeine, is the most useful and reliable. Preparations are available for three methods of administration: tablets for oral use, rectal suppositories, and ampules for parenteral injection. The method of administration varies with the needs of the patient. If nausea and vomiting do not occur early, tablets containing a mixture including 1 mg. of ergotamine tartrate and 100 mg. of caffeine (Cafergot-PB or Wigraine) are the preparation of choice. Initially, two tablets are given at the onset of a headache and this dose is repeated every twenty to thirty minutes until relief is obtained or until six tablets have been given. This cautious, pedestrian method of administration has two advantages. It allows the patient to discover whether he is sensitive to ergot. On rare occasions muscle cramps, nausea, vomiting, or paresthesia may result from taking as little as two or four tablets. If such idiosyncrasy exists, it is well to recognize it as a result of using as small a dose as possible. The second advantage is that this method makes possible a rough approximation of the minimal dose needed to control a headache. Occasionally, a patient will be relieved by as little as two tablets. Those patients who require six tablets taken in

the manner described may find that a subsequent headache is controlled by only four tablets if these are taken at once and as early as possible.

Should this method of administration fail to bring relief it is well to inquire carefully as to the exact method the patient used in taking the medicine and when in the course of the headache he took the first dose. Many patients with migraine are inveterate gamblers. They are always betting, with themselves, that this headache will not be like the 100 or more similar headaches that have preceded it. "If I don't pay any attention, it will go away," or "I'll just work this one off," are examples of excuses they offer themselves for not taking medicine as directed. They must be aided to realize that early use of the medicine in adequate amounts greatly enhances their chances of gaining relief.

If nausea and vomiting occur early in the course of the headache, oral administration of medicine should be avoided. For the headache that characteristically reaches a maximal intensity in a short time, it is well to give a hypodermic injection of 1 or 2 cc. (0.5 to 1 mg.) of ergotamine tartrate (Gynergen) or 2 cc. (2 mg.) of dihydroergotamine methanesulfonate (D.H.E. 45). If there is no relief in one hour, another 1 cc. of either drug may be given. The headache that is slow to reach a maximal intensity may be controlled with a suppository containing 2 mg. of ergotamine tartrate and 100 mg. of caffeine (Cafergot-PB). Another suppository may be given in one hour if the first is not effective.

Methylisooctenylamine (Octin) is a relatively weak vasoconstrictor and less effective than ergot. but is worthy of trial if the patient is sensitive to ergot. The initial dose of 1 cc. (0.1 gm.) is injected intramuscularly and may be repeated in thirty to sixty minutes, if needed.

Inhalation of 100 per cent oxygen has been advocated as a vasoconstrictor to be used early in the course of a migraine attack. Its effect is often disappointing, but its use should be considered if other measures seem unsafe or are impractical.

Treatment given as described above may fail to bring relief and the headache may progress to the third stage. The edema of the vessel walls makes it impractical to try to influence the pain with vasoconstrictors. In this stage, the patient is usually nauseated and vomiting and any medicine should be given by rectum or parenterally. It is

in this stage that the use of narcotics may be justified. Here again, a carefully taken history is of value, since it prevents the administration of those narcotics which the patient has learned from experience may cause him unpleasant side effects. In addition to analgesics, the patient may be helped by the use of sedatives, easily given in the form of rectal suppositories containing a barbiturate. Protracted vomiting may be controlled by the intravenous administration of dimenhydrinate (Dramamine). One cubic centimeter of the parenteral solution containing 50 mg. of the drug is diluted in physiologic saline solution to 10 cc. and given intravenously over a period of two or three minutes. The intravenous use of dimenhydrinate may be tried early in the second stage of a headache; it sometimes controls the pain as well as the vomiting. Needless to say, treatment of headache at any stage is enhanced if the patient retires to a darkened, quiet room.

So-called interval treatment of migraine will not be discussed here. The awesome number of such treatments that have been advised attests to the fact that no regularly reliable or satisfactory method of interval treatment has yet been published. "Yet migraine has been the happy hunting-ground of the theorist, and the problem has been attacked by representatives of all branches of medicine. Each in turn has discovered in migraine phenomena pertaining to his own specialty; each in turn has hit upon the true nature of the malady; in turn, each has found the infallible remedy."¹ If the physician recognizes distinct physical abnormalities in his patient, for example, dental, allergic, endocrine or other, an attempt at their eradication or control is justified. Emotional tension undoubtedly plays an important role in triggering the attacks of many migraine sufferers. Faulty attitudes of the patient or environmental factors that seem to lend themselves to relatively simple manipulation should properly receive attention.

Vasodilating Headache of Short Duration.—The classic example of such a headache is the individual attack of histaminic cephalalgia. The onset and progression to maximal intensity may be so rapid as to seem explosive. These attacks may last as little as ten or fifteen minutes and for that reason any measure used to relieve them must take effect rapidly. Medicine taken orally is seldom effective. In contrast to its frequent failure in migraine, the inhalation of 100 per cent oxygen

during these headaches proves effective often enough to make its trial of distinct value. It is best administered through a well-fitting mask. If relief is not obtained after five minutes of breathing oxygen, the trial may be considered a failure. If a few trials are successful, the patient should obtain a tank of oxygen (such as is used in welding), a reducing valve, rubber tubing and some inexpensive, disposable plastic masks. The major expense of this equipment is the deposit on the oxygen tank and cost of the reducing valve. The deposit is regained when the tank is returned. The valve may usually be returned for some reasonable portion of its purchase price. Since these headaches commonly cause greater trouble at night, the apparatus may conveniently be kept in the bedroom. One patient's headaches were so dreadful and relief with oxygen so prompt that he kept an oxygen tank at home and another in his office. He carried a third and smaller tank in his car.

Should the inhalation of oxygen fail, the most reliable remedy is a preparation of ergot, such as Gynergen or D.H.E. 45 given parenterally. The patient is taught to use a needle and syringe properly and to give the drug to himself. When it is recalled that a patient with histaminic cephalalgia may have four to six attacks in twenty-four hours, the thought of giving so much ergot may seem forbidding. Fortunately, the interruption of one attack by the injection of ergot may rid the patient of all attacks for as long as twenty-four to thirty-six hours, so that such frequent administration is usually not necessary. For those patients who have most of their attacks at night, the use of an ergot-caffeine suppository (Cafergot-PB) at bedtime will often insure an uneventful night's sleep. The patient whose nights have been made miserable for several weeks will consider this something of a miracle.

The patient who has gained respite from the head pains will be eager to know what steps he may take to forestall them in the future. This question has no certain answer, but histamine "desensitization"² may be employed for this purpose and seems to benefit a sufficient number of patients to make it worthy of trial. The patient should be taught the proper technique of making a subcutaneous injection and caring for needle and syringe. A solution containing 0.275 mg. of histamine diphosphate per cubic centimeter may be obtained in 20-cc. vials. Injections of this solution are given twice daily. The initial dose is 0.10 cc.

Each succeeding dose is increased by 0.05 cc. Thus, the second dose is 0.15 cc., the third 0.20 cc., the fourth 0.25 cc., and so on. The amount given at each injection is in this manner gradually increased until a "maintenance" dose is attained. This should not be more than 1 cc. and may be less. If, during the course of gradually increasing the dose, any flushing of the face or any headache is noted the next dose should be reduced to 50 per cent of the dose that caused these symptoms. Subsequent doses should again be increased gradually as described above. Some patients find that any dose greater than 0.70 cc., for example, causes flushing or headache. For such a patient the maintenance dose should then be 0.70 cc. This maintenance dose, whatever it may be, should be continued twice daily for two to four weeks and then reduced to once daily for a month. At the end of this time use of the drug may be stopped if the patient is free of headaches.

The doses of ergot so far mentioned may seem large. The following remarks are made in explanation. While serious complications from the ill-advised use of ergot preparations can and do occur, this danger is overrated. Doses which are usually considered excessive may be taken for long periods with relative impunity as is evidenced by reports such as that of Peters and Horton.³ This is not said for the purpose of suggesting a careless attitude toward the use of these drugs, but rather to combat the overtimid attitude that results in the use of amounts that are too little and too late. As with any potent drug, the dose of ergot should be enough, that is, enough to control the symptoms or enough to demonstrate that the drug is ineffective, either from failure to relieve pain or from the occurrence of toxic side effects.

Some well-defined contraindications to the use of ergot therapy include impaired hepatic or renal function, phlebothrombosis, and severe anemia. Hypertensive cardiovascular disease and angina pectoris present a different problem. Ordinarily the avoidance of use of ergot is advisable. However, the protracted anguish of a migraine attack may have a greater adverse effect on these conditions than the use of ergot if it provides prompt relief. The preparations of ergot commonly used for control of migraine do not contain sufficient oxytocic substance to be capable of altering the course of a normal pregnancy. However, if the patient should take an ergot preparation and suffer some difficulty with gestation, the physician

who prescribed the drug would almost certainly be the recipient of ill will or worse. For that reason, the use of some remedy other than ergot is advisable for the pregnant woman. Fortunately, the onset of pregnancy is usually associated with a diminution of the frequency and severity of migraine attacks.

Cranial Arteritis

The pain of cranial arteritis is in itself usually severe enough to demand treatment, but the ever present danger of blindness is an even more compelling reason for prompt and vigorous treatment. While the use of corticosteroids does not cure the underlying disease, it does halt the progress of the illness, relieve pain and prevent blindness more effectively than does any remedy so far employed. Patients with this condition should be considered as presenting a medical emergency and treated accordingly. On the first day 300 mg. of cortisone is given intramuscularly, one half of the total dose being given on each of two occasions at an interval of twelve hours. On the second day the same schedule is followed but the total dose is reduced to 200 mg. On the third day the total dose may be 150 to 200 mg. divided into four equal portions given orally at intervals of six hours. The latter dose may be continued for about six weeks. At the end of this time the total dose per day may be reduced by 12.5 to 25 mg. every three or four days until it is lowered to 12.5 mg. per day. At this level, administration of the drug may be stopped. An increase of the dose is required if at any time during the period of reduction of dose the symptoms recur or the erythrocyte sedimentation rate rises. Treatment may have to extend over nine to twelve months. In order to prevent serious disturbance of electrolyte balance, the total amount of sodium in the diet should not exceed 2 gm. per day, and 3 to 6 gm. of potassium chloride should be given per day. Before the advent of cortisone it was sometimes observed that removal of a segment of the affected artery was followed by relief of pain. Biopsy of an affected artery is commendable as an aid in diagnosis but should not be relied upon as the sole method of treatment.

Tension Headache

The immediate source of pain in tension headache seems to be prolonged, abnormal tension in the muscles of the neck and head. This in turn is

usually associated with varying degrees of emotional tension. Therefore, efforts at treatment should be directed toward lessening the muscle and emotional tension. The use of simple analgesics, such as aspirin compound, is helpful in the individual attack. In an effort to relieve emotional tension, sedatives such as carbromal, barbiturates or any of the numerous "tranquilizing" drugs may be used. Physical measures, such as local heat, massage and cervical traction, are of definite value in reducing muscle tension. The patient may be instructed in the manner of using these measures and thus continue his treatment at home. This type of therapy has been described in detail by Erickson.⁴ Vasodilating drugs may be of some aid if taken regularly between headaches. Nicotinic acid is inexpensive, is simple to use, and is an effective dilator of extracranial arteries. It is given in doses of 50 to 200 mg. four times a day, thirty minutes before each meal and at bedtime. The patient will be spared an unpleasant surprise if he is cautioned that an occasional dose of nicotinic acid may cause him to flush, especially about the head and neck. This flush appears about ten to fifteen minutes after he takes the medicine and lasts twenty to thirty minutes.

The treatment of headaches can be made, in writing, to seem much simpler than it really is. Occasional failures are bound to occur. Some patients seem refractory or insensitive to all measures mentioned thus far. Adverse environmental factors and complex emotional problems may conspire to make these simple measures ineffective. Admission to a hospital followed by prolonged medical and psychiatric care may be necessary. However, the majority of patients with troublesome headaches can be materially aided if the physician displays an active interest in their problems, encourages regular office visits and uses ingenuity in varying the doses and types of drugs to suit the needs of the patient.

Photosensitivity

NADINE G. SMITH, M.D.
Minneapolis, Minnesota

THE SUN has been worshipped for centuries, but only recently has much attention been paid to the undesirable consequences of chronic sun exposure and to photosensitivity, both in the medical literature and the lay press. Dermatitis caused by the sun are increasing in number due to the use of new drugs which produce photosensitivity reactions. The national morbidity from sun exposures is high and includes skin cancer. From a cosmetic standpoint the sun ages the skin, dries and fissures the lip, and severe sunburn may result in mottling of skin. The only proven benefit derived from the sun in the healthy individual is the production of vitamin D in infancy. The doctor must know how to prevent as well as to treat the unfortunate results of chronic or acute sun exposure. He must know which diseases will be aggravated by light, and he should have something to offer the patient who is hypersensitive to the sun's rays.

Etiology of Photosensitivity Diseases

Numerous classifications of photosensitivity diseases exist. Kesten¹ presents these diseases under four headings: those forms occurring in apparently normal skin, those occurring in skin that is presumably abnormal, those appearing as a "Koebner phenomenon," and those forms occurring in skin after prolonged exposure to sunlight. This paper will deal only with diseases grouped under the first two headings. The types of reactions occurring in normal skin include solar erythema, chronic polymorphic light dermatitis, solar urticaria, and photodynamic dermatosis.

Different portions of the sun's spectrum produce different diseases. Some of the basic factors of this radiation must be understood before a particular disease can be properly evaluated. Topical therapy will be ineffectual if knowledge of the

absorption spectrum of the sun protective agent is lacking, and it does not coincide with the action spectrum. We are concerned with the sun's rays which lie between 2900Å and about 8000Å. The ultraviolet range is between 2900Å and 3900Å; visible light between 3900Å and 7700Å; and infrared extends beyond. Window glass filters out all radiation below 3200Å. Moisture does not remove erythema-producing rays, whereas dirt particles do. This explains the severe sunburns which occur on overcast days. There is considerable variation in the quantity of ultraviolet radiation transmitted at different times of the day or year. In the winter in Minnesota there is very little short wave ultraviolet in the sun's rays, but reflection from snow and water is a significant factor. The body is normally able to protect itself to some extent from sunburn radiation, because the horny layer of the skin, sweat, and melanin pigment all absorb these wave lengths. The thickening of the horny layer is the most important factor. Injury from the sun's rays occurs in the prickle cell layer so that pigment located in the basal layer is of little protective value.

The rays producing erythema or sunburn lie between 2900Å and 3170Å, with a peak at 2967Å. They constitute less than 0.2 per cent of the total sun's radiation. These rays produce the polymorphic light eruptions and most cases of solar urticaria; however, some cases of both diseases have been reported which were produced also by longer ultraviolet or visible light and one case by infrared.

In the photodynamic group of reactions it is assumed that the action spectrum is the same as the absorption spectrum of the substance producing the reactions; for example, porphyrins absorb light waves of between 4000Å and 5000Å. It is in this range that various investigators have demonstrated photosensitivity following the injection of hematoporphyrin. Most cases of phytophotodermatitis are produced by wave lengths be-

Dr. Smith is instructor in the Department of Dermatology of the University of Minnesota. This paper was presented as part of the course in dermatology given at the Continuation Center, January 7, 1957.

tween 3340Å and 3660Å. When longer wave lengths are incriminated, a physical sunscreen must be used for protection. Ordinary chemical sunscreens do not absorb light waves above 3900Å, but most absorb waves below 3100Å.

Diagnosis of Photosensitivity Diseases

With the exception of solar urticaria, morphology is of relatively little help in diagnosis. The polymorphic eruptions often present a characteristic clinical picture but may simulate other dermatitides. Cases of porphyria may not always show the typical bulla; consequently, porphyria must always be ruled out in the diagnosis. A history of onset or aggravation following severe sunburn or sunlight exposure may be helpful. This may not be obvious from the history because many of these reactions are delayed. The most useful factor in diagnosis is localization. The lesions usually occur on the lateral aspects of the arms, especially the left arm due to exposure while driving a car. Other frequent sites are the pinna of the ears, the malar eminences, and the lower lip. Another useful aid in diagnosis is testing with sunlight or artificial light sources combined with glass filters. By this means it may be possible to reproduce the lesions and to delineate the range of the spectrum involved.

Polymorphic light eruptions may be simply erythema with or without edema. They may be eczematous, prurigo-like, or they may occur as chronic inflammatory plaques. In contrast to solar urticaria, there is a delayed reaction time in the polymorphic group. The lesions may resemble lupus erythematosus, but they do not scar nor is there accompanying systemic involvement. Although this form is probably on an allergic basis, passive transfer has rarely been accomplished. Epstein points out that the two diseases, solar urticaria and polymorphic light eruptions, have been seen in the same patient and are probably closely allied.²

There have been seventy cases of solar urticaria reported, but the disease is probably more common than the literature indicates. The ratio of females to males in the cases reported is three to one. This sex distribution is also true of the polymorphic light eruptions. As mentioned previously, the most common type of solar urticaria is that form caused by wave lengths under 3200Å. In these cases passive transfer has often been dem-

onstrated. The urticaria is usually localized and without pseudopods, although it may be generalized with an accompanying shock-like picture. Urticaria begins suddenly and may be associated with an underlying infection. Attacks may last a few hours to several days. In those cases caused by drug ingestion the prognosis is good after the drug is discontinued. In other cases the prognosis for a cure is poor, and the disease may persist for decades. The prognosis seems to be the worst in those forms caused by light in the violet-blue range. Hyposensitization has been achieved by gradual exposure.

The terms photodynamic (phototoxic) and photoallergic deserve some clarification. Phototoxic refers to those reactions which would occur in all persons if the amount of substance present and the amount of radiation were high enough; for example, all persons if given a sufficient quantity of sulfanilamide and an erythema dose of ultraviolet will manifest photosensitivity. Fortunately, the amount of drug required for this response is beyond the usual dosage. Photoallergic reactions by contrast will occur only in a certain few people regardless of the quantity of radiation or offending substance present. Photodynamic reactions are divided according to whether the substance is endogenous or exogenous. They may be photochemical reactions, or they may be caused by plant extracts. Many of the latter are capable of photosensitizing, especially those belonging to the pea, parsley, mulberry, and rue families. The rinds of limes are notorious offenders in southern communities. A case has been reported recently in which carrots caused photosensitivity.³

Drugs which produce photosensitivity reactions are the sulfas, barbiturates, para-aminobenzoic acid, salicylates, chlortetracycline, antihistamines, especially phenergan, chlorpromazine, and phenylbutazone. The widespread use of chlorpromazine has produced numerous cases of photosensitivity. The dermatitis in these cases is associated with a peculiar type of brawny edema. Dosage levels as low as 50 mg. per day have produced this phenomenon, and larger dosages do not produce more reactions.⁴ Reactions are produced only by wave lengths between approximately 3025Å and 2968Å.⁵ The lesions usually disappear upon cessation of the drug, and the drug may sometimes be re-administered without recurrences.

This is not the case with Phenergan, which may produce long-lasting photoallergic reactions. Since chlorpromazine and Phenergan are closely related chemically, it is understandable that they produce similar reactions.

Para-amino benzoic acid is among the drugs listed as photosensitizers. This also is the drug of choice for use as a sun screen. It has been found that the salts and esters of para-amino benzoic acid are more potent sensitizers than the acid itself. Sams⁶ has done considerable work in the field of contact photodermatitis. Of 290 such cases, lime oils accounted for 186. Forty-three were caused by perfume or toilet water, notably Shalimar. Sams also reported on reactions from two sunscreensing preparations, Skolex and Neo-A-Fil. The patients were not contact-sensitive to these creams. Both functioned as effective screens for sunburn radiation, but at the same time sensitized the skin to ultraviolet rays of longer wave length.

Of those forms of photosensitivity occurring in skin that is presumably abnormal, I shall discuss only porphyria cutanea tarda, xeroderma pigmentosum, and vitiligo. Porphyria cutanea tarda occurs most commonly in men of middle age and is often associated with diabetes, chronic alcoholism, and some hepatic abnormality. It must always be included in the differential diagnosis of photosensitivity reactions occurring on exposed areas. It is not rare since more and more cases are being discovered. Clinically, there is hyperpigmentation and hypertrichosis, and the active lesions are bullous. Often only excoriations and crusting are seen. Lesions occur most commonly on the dorsal aspects of the hands and the pinna of the ear. When there are associated abdominal and neuropsychiatric symptoms, the disease is termed mixed hepatic porphyria. Fluorescence of a specimen of urine will aid in the diagnosis. We have been unable to reproduce these lesions with the carbon arc lamp, and this has been true for the most part with other investigators in the field. Trauma may play an equally important role, but this has not been clearly established. These patients do fairly well when abstaining from alcohol and when adequate diets with vitamin supplements are prescribed. Since porphyrins absorb light waves of around 4000Å, chemical sunscreens are not effective.

Xeroderma pigmentosum is a rare hereditary

disorder beginning in childhood. The patient presents telangiectasia, pigmentation, atrophy, and keratoses, the latter terminating in carcinomas. These patients seldom survive into adult life. They must be protected from the sun. Erythema producing waves have been implicated, and sunscreens are protective. The keratoses must be carefully watched for early signs of cancer.

Vitiligo is a rather common dermatosis which is not only cosmetically disturbing but which also prevents outdoor activity without protection. In contrast to albinism, melanocytes are usually present, but they do not function. It is rare for vitiliginous areas to become pigmented spontaneously except in younger persons. Sunscreens will prevent sunburn in the affected areas, and reduce the pigmentation in the surrounding skin, making the depigmented areas less noticeable. The recent reports on the use of psoralens are probably overly optimistic; nevertheless, they offer the patient with vitiligo more than any therapy to date.

Therapy

Therapy of photosensitive dermatitides leaves much to be desired, but at times may be gratifying. If there is a photosensitizing agent involved, this should be eliminated. In those forms occurring in apparently normal skin, the best approach is gradual exposure in combination with antihistamines taken orally. The desired goal is a thickened horny layer and an increase in melanin pigment. Anything which entirely prevents this, such as zinc oxide, should be avoided. Topical preparations should protect against 10 MED's (minimal erythema doses) of sun. There are three types of sun protective medications which are used topically.⁷ The first type includes the sun screens. These are usually aromatic compounds which do not absorb light waves above 3900Å and usually absorb those below 3100Å. Para-amino benzoic acid, ortho-amino benzoic acid, and salicylates are examples of chemical sunscreens, and these are contained in most commercial preparations. They allow some erythema-producing rays to be transmitted so that tanning may occur. Second, the vehicle may also absorb some light. The third type includes sunshades or physical sunscreens, and they act by scattering light. Applied in heavy coats, they occlude all radiation. Examples of this type are zinc oxide or titanium oxide. A-Fil cream contains titanium

oxide and thus protects against the longer wave lengths. The sunshades must be used either alone or in combination with chemical sunscreens in the photo-dynamic group of eruptions and anywhere else when longer wave lengths precipitate the reaction. Desirable points to consider in the choice of topical preparations are as follows: they should absorb most but not all radiation below 2900Å; nevertheless, chloroquine seems to be genic, stable, and should not discolor. They should stay on for several hours, be cosmetically acceptable, and relatively cheap. Men will use the colored creams, but women prefer the alcoholic lotions. Antihistamines applied topically absorb the proper rays, but they are sensitizers and should be avoided. The preparation of choice is 15 per cent para-amino benzoic acid in a water-washable ointment base or in a lotion. There are several commercial preparations available which protect against 10 MED's of sun.

Certain internal factors deserve attention. It is important to eliminate underlying infections. Diet directed toward protecting the liver is indicated not only in porphyria but also in other photosensitive diseases. Abnormal liver function is often found in the latter. Lamb recommends hormonal therapy for severe cases of polymorphic light eruptions.⁸

Antihistamines taken orally have been shown to produce some increase in tolerance to the sun. They are of use in solar urticaria, as well as early in the season during the stage of gradual exposure. It is well to remember that they may act as photosensitizers in some persons.

Antimalarials are a relatively new addition to the pharmacologic armamentarium in these diseases. Chloroquine absorbs light waves of around 3400Å, and atabrine absorbs those of around 2900Å; nevertheless, chloroquine seems to be the drug of choice. In a recent study plaquenil sulfate appeared to be as effective as chloroquine, and there was a lower incidence of side effects.⁹ Liver damage is a contraindication to the use of these drugs. Experimentally, chloroquine does not decrease the erythemogenic response, but clinically it reduces the abnormal papular reaction in the polymorphic light eruptions.¹⁰ Epstein has quoted good results in solar urticaria.

Finally, mention must be made of the psoralen compounds. These drugs come from the fruit of the *Ammi majus* Linn plant. The most active

principle is 8-methoxy psoralen. It absorbs wave lengths between 2200Å and 3500Å. Taken orally, it is said to increase melanogenesis and to increase tolerance to ultraviolet rays. The latter is a moot point. Fitzpatrick believes that it increases all cutaneous responses. Topically, it decreases tolerance to the sun, and erythema and vesiculation occur if exposures are not gradual. It is relatively nontoxic, but it should not be used in the presence of liver damage. Fair results have been reported in patients with vitiligo who were maintained on the drug for at least four months.¹¹ It must be combined with exposure to ultraviolet rays, and the sun itself is apparently superior to any artificial source.

Summary

A discussion of the etiology and diagnosis of photosensitivity diseases is presented. A therapeutic approach is outlined which includes (1) topical applications and (2) internal measures with (a) antihistamines, (b) antimalarials, and (c) the psoralen compounds.

Treatment of Tuberculosis Today

EJVIND FENGER, M.D.

Oak Terrace, Minnesota

THE United States Public Health Service reports that there are currently about 400,000 active cases of tuberculosis in the United States at any one time, about one third of which are hospitalized, one third are known cases at home, and one third are undetected cases. The physician in general practice has a responsibility to each of these groups. It is to him that the patient often comes for diagnosis, and returns for post-sanatorium follow-up. For the patient who cannot or will not be hospitalized, he must prescribe and administer treatment, and he must be ever watchful for the undetected case, so that it too can be isolated and treated.

Unfortunately, tuberculosis remains a chronic, infectious disease in spite of our best efforts to combat it, but the past ten years have brought tremendous changes. Ten years ago, we discussed the type and duration of collapse therapy, and measured our success or failure by mortality rates. Now, we confer on the type and duration of drug therapy, the time and extent of resectional pulmonary surgery, and the spotlight has shifted to morbidity rates.

The number of deaths from tuberculosis has decreased between 15 and 20 per cent each year for the past few years; the latest figures for the United States are 9.4 per 100,000 in 1955, and for Minnesota 4.0. However, the number of new cases reported has decreased only about 3 per cent per year for the past five years.

Considering these rapid strides, what is accepted as adequate tuberculosis treatment today? First of all, bed rest is still basic. To get the patient to relax mentally and physically is a constant, time-consuming task. There are at least three theories to explain the effectiveness of bed rest, according to Mitchell:

1. Reduction in metabolism. Reduction in activity reduces the oxygen requirement and hence, the amount of breathing.

2. Alteration in pulmonary circulation. Because the systolic blood pressure in the right ventricle is only 20 per cent of that in the systemic circulation, it has been reasoned that the pulmonary circulation in the apices of the lungs in the vertical position is relatively reduced. The resultant increase in oxygen and decrease in carbon dioxide in the apical alveoli produces a medium favorable for the multiplication of tubercle bacilli.

3. Reduction in the lung volume. In the horizontal position, there is a reduction of lung volume from 10 to 40 per cent, producing a mild bilateral collapse caused by the rise in diaphragm. It goes without saying that bed rest is most effective in the acute and/or the progressive case. It is least effective in the chronic case.

The psychological effect of bed rest is important. It helps to make the patient and his family understand that he is ill and needs treatment. With hospitalized patients, it helps to keep them in the hospital. The patient always has a tendency to take more activity than is prescribed, and recalcitrant behavior more often occurs among ambulatory patients.

Most authorities agree that a period of hospital care is still necessary for the active adult case of tuberculosis. He will learn the physical facts about his disease; for instance, that it is a generalized disease with local manifestations, and that it takes a long time for the average case to become inactive. Contagious technique can be taught to both the patient and his family. He will learn how to cover his cough at all times, how to dispose of his sputum; he will learn the importance of systematic rest and the avoidance of worry and fatigue. The patient can be better followed as to the tolerance of drugs and the improvement in his disease. This is especially true in the matter of x-rays and bacteriology. The patient will also learn the tremendous importance of uninterrupted drug therapy. His physician will have a better opportunity to judge the proper time for surgery, if it is indicated.

In the hospital, the patient will also have the benefit of occupational therapy, schooling, re-

Presented at the Center for Continuation Study, University of Minnesota, April 13, 1957.

Dr. Fenger is Clinical Associate Professor of Medicine, University of Minnesota, and Assistant Medical Director, Glen Lake Sanatorium, Oak Terrace, Minnesota.

habilitation and the assistance of the medical social worker in solving the personal problems of a long-term illness.

It could be argued that in a few types of recently diagnosed tuberculous cases, the patient could be treated at home. The active, primary tuberculosis patient has done well at home. The pleural effusion patient, and the clinical, silent, minimal patient may be treated thus, if he is co-operative, and has a good emotional and mental make-up so that he can, and will, follow instructions as to the cure. Much depends on whether the home conditions are such that the patient can be isolated and allowed to rest.

With rest, anti-microbial drugs are given, and these are now known to be very effective. We have a number of such drugs. They are all bacteriostatic, and are given to all patients with active tuberculosis. With them, we obtain a favorable effect on the reversible component of the disease process. Thus, best results are obtained in treating those patients who have recently developed lesions. The principal drugs in use are:

1. *Streptomycin*.—This drug was the first to show potent effects as an anti-tuberculous drug. It is given intramuscularly, generally one gram twice a week. It does have toxic side effects, such as skin eruptions, fever, headaches. It may also have toxic effects on the vestibular portion of the 8th cranial nerve, resulting in dizziness.

2. *Isoniazid (INH)*.—This drug is given by mouth. It is well tolerated. The dose is 100 to 200 mg. twice daily. This drug may produce peripheral neuritis. In older people, the use of 25 mg. of Pyridoxine daily may prevent peripheral neuritis.

3. *Para-amino-salicylic acid (PAS)*.—This drug is usually given by mouth, the preferred dose being 12 grams daily. It is a bad tasting drug, not as effective as streptomycin or isoniazid, but is very useful combined with streptomycin or INH. Either of these combinations delays markedly the emergence of resistance of the tubercle bacilli to these drugs.

4. *Viomycin*.—This is given intramuscularly. Its anti-tuberculous action is much like streptomycin, and it is usually used as a substitute for streptomycin. The dose is 1 gram twice daily, twice a week.

5. *Pyrazinamide (PZA)*.—This drug is given by mouth, 1½ grams to 2½ grams daily. It is somewhat toxic to the liver, so that liver function tests must be performed routinely. This drug is very effective when given with isoniazid. It must be emphasized that these drugs should be used in combination, and there is no advantage in using more than two drugs at a time, except when treating miliary tuberculosis or tuberculous meningitis. For these types of tuberculosis, the preferred treatment is streptomycin grams 1 daily, PAS grams 12 daily, isoniazid 200 mg. twice daily, until the acute phase has subsided.

The tremendous value of the drugs in reducing the toxicity of the patient, in reversing the progressive nature of the disease, in eliminating the symptoms and signs of tuberculosis, and in speeding up the active healing of the lesion, has produced a tendency among tuberculosis workers to relax contagious technique. But it must be remembered that the drugs do not sterilize the lesion, and for the open positive case, it generally takes two to three months before they are really rendered negative.

Emergence of resistance to the drugs used will be found sooner or later in the open cavitory case where we cannot convert the sputum to negative. Drug resistance is suspected when the patient complains that he is not feeling as well as he has been, or that he is raising more sputum, or when the x-ray does not show the expected improvement. Testing of cultures for resistance should be carried out routinely. Complete resistance should lead to consideration of surgery to close the supposedly open cavity, and a change to another drug regimen is indicated.

Interruption in drug therapy hastens the emergence of resistance very much. Because of this, the patient must be impressed with the idea of taking the drug even if its taste is bad, or abdominal symptoms and complaints arise. The duration of drug therapy should be from eighteen to twenty-four months when streptomycin, PAS, isoniazid in any combination of two are used, and this applies where they have been effective in converting the patient to negative. Many patients are sent home while still on drug therapy, but continue its use while on limited activity or occasionally on full activity.

Resection surgery has replaced collapse surgery. It may mean taking out a small piece of lung tissue, or it may mean taking out as much as one

complete lung. The improvement in anesthesiology and in chest surgery has made these procedures very safe, and we believe, very effective in rendering the patient inactive, and in preventing relapse. The mortality figures depend on the type of case, but are quoted as 1.2 to 10 per cent. The complication rate is low when the patient is fully prepared for surgery, and has been well covered with effective drugs.

The timing of surgery is very important. The treatment of the average case is well defined, but differences of opinion may arise with a far advanced case with cavitation, and also with the minimal case which has some residual disease. Indication for the resection of the residual cavity or caseous nodules of 1 cm. in diameter or more is now widely accepted, and is also indicated for tuberculous bronchiectasis, atelectasis, and/or extensive damage of a segment, a lobe, or a complete lung, especially if the patient has positive sputum. This is especially true of the younger patient who has a good vital capacity, and who has much to look forward to, if he can become classified as inactive. The older patient, who has an impairment of the heart or vascular condition, or a lung condition such as emphysema, may be treated without surgery.

After surgery, the average patient continues the cure, because only the gross disease has been removed. There are still foci in the lung and glands that need treatment. The length of time in bed after surgery depends on the extent of the disease, the extent of the surgery, and the activity of the lesion removed by surgery. The average patient stays in bed four months after surgery and is then ambulated.

During the postoperative and ambulatory period rehabilitation plans are fully developed. At the time of discharge, the patient must be impressed with (1) the necessity of continuing with uninterrupted drug therapy; (2) the necessity of periodic check-ups, especially x-rays and blood studies every three months for the first year and every six months thereafter; (3) the need for starting schooling or work part-time, gradually increasing to full-time.

Since about half of the known patients with tuberculosis are being treated outside the hospital, the Public Health Service has shown particular concern for this group, and has made a detailed study recently. It shows that community facilities such as clinics, public health nursing and social

service are found in most urban areas, but almost half of the rural areas studied have no clinics, 10 per cent have no public health nursing service, and 80 per cent have no social services outside of the financial assistance provided by departments of public welfare. The study also emphasized that local health departments should be particularly concerned about the spread of tuberculosis, because of the presence of active cases in the community. With present-day treatment so clearly defined, the non-hospitalized patient should have the benefit of every facility offered to the hospitalized patient, though this is often harder to achieve on an individual basis and more expensive than where it is concentrated within the hospital.

The person who has an undetected case of tuberculosis is potentially the greatest menace, and constant vigilance in case finding is the only answer. It is now agreed that mass chest surveys alone will not lead to eradication of tuberculosis, but a continuing survey in the doctor's office will capture one third of the population, since that is the number who see their physicians in a year. The x-raying of hospital admitted patients has proved to be effective, since the number of cases found are two to four times as high in this group as in community surveys. The diagnostic studies and proper disposition of the case become the mutual responsibility of the attending physician and the local health department. The tact and understanding with which this initial situation is handled often determines the patient's future willingness to cooperate in the matter of isolation, hospitalization and treatment.

In conclusion, I would like to quote from the statement by the Committee on Therapy of the American Trudeau Society, which says:

"From the facts now available, there is no evidence to support a reduction in the amount of rest therapy from that of past practices, except as this may be justified by an earlier attainment of an inactive status of the disease . . . the total period of disability, although greatly shortened on the average with drug therapy must still be estimated at a minimum of one year. Every person with potential infectious tuberculosis should be in a hospital bed."

Counseling Parents of Gifted Children

RUTH STRANG, Ph.D.
New York, New York

TO COUNSEL gifted children, we must first find them. To identify them, we must know for what to look. After we know this, we must learn *how* to look for them—what methods and instruments of identification we can use. After we have identified them, we must know how to help them develop their potentialities. Counseling is only part of this process.

The counselor has four main functions: (1) To work with and through school teachers; (2) to counsel with individual students and parents; (3) to suggest changes in the school policies and environment in light of the needs of the gifted students; and (4) to discover and use community resources for the best development of the gifted. In the past, counselors have spent much of their time interviewing students and parents and have neglected these three other very important functions through which they can greatly extend their influence.

Counselors can help teachers identify gifted students. For example, in the Long Beach, California, school system counselors in each school systematically went through the pupil personnel records to identify students with IQs over 120 and others who showed some special talent. They called in these students, together with their parents when possible, for a conference. In this conference, they discussed the student's potentialities in relation to educational and vocational opportunities. After the conference, the counselor sent a memorandum to the student's teachers suggesting things they could do to enrich his program. The result of these conferences was to increase the student's sense of responsibility for his gifts and to alert parents and teachers to school and community opportunities for their development. Thus the counselors aid in the identification of gifted students; they help the gifted individual to understand himself and get the experiences he needs in the school and community. They help

the parent to avoid the extremes of exploiting their gifted children or of denying them the education and encouragement they need. And their concrete suggestions help teachers to meet the needs of gifted students in their classes.

There are three main ways of identifying gifted children: (1) Through their cumulative personnel records; (2) through the results of intelligence and achievement tests; and (3) through teachers' observation of them day by day.

The percentage of intellectually gifted will vary from school to school. In one school district 4 per cent of the students scored 125 IQ or higher on standardized intelligence tests; in another school district there were 29 per cent on this level.

The central task of counseling the gifted is to help them understand themselves and feel a sense of social responsibility for their lucky combination of heredity and early childhood experiences.

With young children, guidance in their daily activities is most effective; this is guidance while teaching. Adolescents welcome the opportunity to appraise themselves. They want the counselor to interpret the results of tests and to help them develop a realistic concept of the kind of person they can become. The counselor should help them to see that the world needs them; to think through what may be blocking them; to understand their parents—perceive them in a different light; to distinguish between conditions they can change and conditions that they have to accept at present.

It is very important for the counselor to try to see situations from the child's and the adolescent's viewpoint and to try to understand how they feel. In the panel discussion by gifted youngsters, we obtained a glimpse into their world. They gave us clues as to why some bright students fail in one or more subjects, the kind of teachers they would like to have—teachers who are interested in every student and take time to know them as individuals; who enrich the class work and give all a chance to participate; who know what each student can be expected to do, and provide a program geared to their talents. These

Talk and panel discussion at the University of Minnesota Center for Continuation Study, institute on "The Exceptional Child in Minnesota," Tuesday, October 2, 1956.

Dr. Strang is at Teachers College, Columbia University, New York City.

youngsters are usually eager to learn; they are bored and dissatisfied with dull books and poor teaching. But they also show sympathy for and understanding of the heavy load that counselors and teachers carry. Gifted young people speak with clarity, directness, and vividness. We should listen more to what they say. We can learn much from them.

In counseling parents, too, it is important to help them see things through their children's eyes. It is also important, through very skillful counseling, to help parents understand their own feelings and why they behave as they do toward their gifted children. Parents have many attitudes toward their gifted children:

1. *Parental Attitude of "Whatness" rather than "Whoness,"* as the late Dr. Plant expressed it, concerns primarily their child's achievement and that the child be a credit to them and increase their prestige. Some gifted children sense that they are not loved for themselves, and resent this, even to the extent of sometimes failing in school.

2. *Parental Attitude of Jealousy* toward the gifted child; as such, some parents "can't take" the child's superiority to them; it makes them feel inferior.

3. *Parental Attitude of Hostility.* Sometimes, just because the child reminds the parent of someone whom he hates, the original emotion is reintegrated.

4. *Parental Attitude of Indifference.* Parents are too busy, the child does not have a supporting relationship and may feel that what he accom-

plishes doesn't matter, because no one really cares what happens to him.

5. *Parental Attitude of Possessiveness.* Some parents take credit for their child's achievement and try to absorb the child and keep him dependent.

6. *Parental Attitude of Boasting.* Some parents embarrass the child by making him seem different from his friends.

7. *Parental Exploitation of the Child.* Some parents force him to practice long hours, exhibit him and forget that "though he is gifted, he is still a child."

In counseling parents, the counselor should help the parent to realize the importance of the first years of life and the security and freedom to explore that comes with being loved. Dorothy Barclay summed it up by saying, "Lead the good life and love that baby." Through preschool years, the parent can help the child most by providing a "lush environment"—material, equipment, affectionate relations—letting him take the initiative in using this environment, and giving encouragement and approval for his genuine successes.

In counseling both parents and children, it is most important "to inspire them to effort." Dr. Albert Schweitzer has expressed this as follows:

"Whatever you have received more than others in health, in talents, in ability, in success, in a pleasant childhood, in harmonious conditions of home life, all this you must not take to yourself as a matter of course. You must pay a price for it. You must render in return an unusually great sacrifice of your life for other life."

THE ADVANTAGES OF PRIVATE MEDICAL CARE

"May the love for my art actuate me at all times; may neither avarice, nor miserliness, nor thirst for glory, nor for a great reputation engage my mind; for the enemies of Truth and Philanthropy could easily deceive me and make me forgetful of my lofty aim of doing good to Thy children."—*Daily Prayer of a Physician* by MAIMONIDES

The art of medicine is the Great Art. Its practitioners are dedicated; its appreciators are fervent. Surely, it is the wish of all thinking, discerning men that members of the medical profession know an atmosphere which will enable them to maintain the high quality of health care that they are giving Americans at the present time. That atmosphere is one which is free from government control or intrusion. American medical men possess this freedom now, and they must continue to possess it.

A look at the advancements in the health standards of the American people will readily show us just what has been accomplished by doctors operating under this private practice system.

Since the founding of our nation, life expectancy has increased thirty-nine years. Contributing factors lie in all fields of medicine. Since 1900, the death rate has increased for eight diseases, while it has decreased for twenty-one diseases. The increase is due to the fact that, since that year, the population of America has doubled. For every 1,000 babies born in 1957, some 130 live who would have died fifty years ago. The number of people over sixty-five has quadrupled, and these people account for the marked rise in the death rates for cardiovascular diseases, cancer, and other diseases of old age. The decrease is due to the discovery and perfecting of antibiotics, improved surgical methods, quicker diagnosis and reporting, and to the work done in the field of preventive medicine.

This editorial was the prize-winning essay in the 1957 Essay Contest for High School Students sponsored by the Association of American Physicians and Surgeons Freedom Programs in cooperation with the Minnesota State Medical Association. The author was a Senior student in the Olivia, Minnesota, high school at the time of writing.

Such splendid achievements could not arise from a profession with low standards of quality. The medical profession requires of its prospective members ten years of advanced education in any of the nation's eighty-two approved medical schools and under intern and residency programs. Post-graduate courses are offered by schools, societies, hospitals, and other health agencies. Standards are elevated in auxiliary fields of medicine, such as laboratory technology and occupational therapy. Financial aid can be secured by deserving medical students. A record number—7,686—entered medical schools in the 1955-56 academic year. What may appear to be, in some areas, a shortage of doctors, in actuality is maldistribution. This is being remedied by placement programs which inform communities of doctors desiring locations and informing doctors of communities desiring medical care.

One of the arguments for socialization of medicine frequently used by uninformed people is this: "If the government takes control of medicine, we'll get free medical care." Medical care, like every other necessity, costs money. There is no reason why anyone should hesitate to go into debt to meet medical costs. There are three ways that a man can pay for medical care:

1. *Cash*.—It is cheaper to pay for home or office calls than to pay taxes to the government on the chance that one might need this kind of service.

2. *Savings, securities, loans*.—Should a man find it necessary to delve into his savings to pay a medical bill, he can do so. If this is not necessary, the savings will remain on hand to meet other types of expenses that may arise. If medical bills were met with federal taxes which, in this case, are compulsory savings, a man could not use these funds for any purpose other than to meet medical expenses.

3. *Commercial insurance*.—In exchange for premiums, one is paid for the costs of more serious illnesses and operations. The uncertainty of a large expenditure is replaced by the certainty of

small one. The advantage of voluntary health insurance over compulsory health insurance is this: The individual reserves the right to select his own doctor and hospital. At the present time, over 60 per cent of the estimated eligible population carries some type of voluntary hospital expense coverage, and approximately 50 per cent is protected against some of the insurable costs of surgery. The voluntary health insurance movement has already surpassed the goals originally charted by the pioneers in this field. It has been on a voluntary basis that all great progress in America has been achieved, and only on that basis can the nation be assured of progress in this field.

A look at the country of England will show some of the dire results of the socialization of medicine. Under the National Health Program, that country proposed to give the indigent, the poor, the average, and the wealthy the same quality and quantity of medical care, and maintain the quality and quantity that the wealthy were accustomed to under private practice. What happened? In London, wealthier districts have an average of one doctor for 1,261 patients, and poorer districts have twice as many patients per doctor. The farming and mining communities suffer even more from lack of medical services. In February of this year, the British Medical Association advised 21,000 English general practitioners seeking a pay raise to quit Britain's socialized system of medicine. The Association recommended the adoption of a pay-as-you-go plan.

From bitter experience, Britain has learned some of the inevitable results of government medicine. (1) Administrative costs of collecting the taxes and redistributing them as sicknesses occur make the entire program less than worthwhile. (2) The physician-patient relationship, always confidential, has been disturbed by this third party intruder, the government. (3) Physicians lose autonomy in diagnosis and treatment that they possess in private practice. (4) Political influences enter into the sphere of medicine. (5) Regimentation occurs in conditions of employment for doctors: the number of hours they must work, their income, and their location. (6) Standardizing the treatment of patients slows down research.

Should anyone feel that the indigent and the chronically ill are being neglected under America's present system of medicine, let us investigate these areas. The chronically ill, of course, are ex-

cluded from private medical plans because the risk is too great. However, in this country there are private institutions that give considerable amounts of aid to the aged, the sick, and the handicapped. Doctors often treat these people at reduced costs. Indigent people are those who can neither afford medical care nor the other necessities of life. They are supported by welfare programs, and are the only people who should receive government aid. If the government stepped in to furnish all of us with medical care, all private resources would dry up, and the taxpayer would have to shoulder the entire load. The government already takes one-third of our income, so why make it necessary for it to take more, when private medicine is less expensive and so much more efficient? Let us not forget that it is the intrinsic nature of bureaucracies to get bigger and bigger, more and more wasteful, costlier and costlier and, at the same time, to get further and further out of touch with the individual and his or her particular needs.

In 1939, in a small country town, a woman was stricken with simultaneous influenza and pneumonia. For several days, her life hung by a thread, and during these days her family doctor was unfailing in his efforts to strengthen that thread. It was a personal matter with him; a battle in which he pitted himself against death itself. In the late hours of the night and the small hours of the morning, he was available to administer stimulants when it seemed the thread could hold no longer. As a last resort, this country doctor sent to a larger city for a new drug that had just appeared on the medical scene and about which, through his constant studying, he had just learned. This forerunner of the "miracle" drugs—sulfanilamide—along with the doctor's dedicated care, saved the woman's life.

Picture this same case under socialized medicine. During the day, the doctor would have been too harrassed by petty rules and regulations of diagnosis and treatment to give his undivided attention to the saving of this life. After hours, when stimulants were needed immediately, the "night doctor" would have to be called. In all likelihood, there would have been no case-continuity nor any of the vitally important feeling for the patient on the part of the "night doctor" working his "shift." When the new drug was wanted, there would have been red tape to cut, and forms

and requisitions to fill out. By the time the drug would have arrived, the thread of life would have been completely and finally severed.

When I see this woman now, eighteen years after her illness, a gracious old lady bringing joy to all those around her, it seems to me that she is a living embodiment of the advantages of private medical care.

TAUTOLOGY OF FARROT

The tautology of Farrot is an old disease that has been with us for a long time. Various authors and writers have described this or that facet and phase of it, but no one has described its tenacious, stubborn tendency to recur intermittently among physicians. Farrot*, himself, first described it as a malady afflicting Continental politicians—and, in fact, it is indeed endemic among politicians, without apparent geographic restrictions.

Despite Farrot's probable priority in being the first to describe this condition, we can well afford to eliminate his proper name as an eponym for most of the subsequent discussion which follows. Perhaps the briefest and most succinct (and therefore to be eyed askance) definition of tautology is the dictionary's: "Needless repetition of meaning in other words . . . an instance of this . . . 'audible to the ear'." This disorder commonly takes subtler forms that are less obvious when it appears amongst physicians.

*Farrot, Muguet deC.: *La tautologie étouffante chez les politiciens malhonnêtes*. *Allgemeine Monatschrift generale de Philologie*, 10:vi-xii (Winter Issue) 1921-2.

In its average, run-of-the-mill form, tautology of Farrot in physicians might show itself as:

"Her temperature showed a brief, transient elevation."

"He first showed splenomegaly or enlargement of the spleen last year."

"Oftentimes the patient has no warning . . ."

The more flagrant, but still benign forms manifest such presenting symptoms as:

"He died of a fatal peritonitis."

"We found he had hepatic cirrhosis of the liver . . ."

"A contributory cause was arteriosclerosis of the vessels . . ."

As one can easily picture, the mature forms when the disease is fully developed, can be malignant (the clinical laboratory may adduce corroborative evidence in the form of a higher titer of verboojuice than of technical waffle). We wait with hair-bleaching expectancy for a report of full-blown tautology of Farrot in a physician who ends his talk at staff meeting with:

"We are confident that we should surely have foreseen in advance that we would retrogress backward . . ."

H.G.M.

DOCTOR MYERS RETIRES

After forty-two years of distinguished service to the University of Minnesota, Dr. J. Arthur Myers has reached the age of compulsory retirement from academic service and responsibilities. Few persons can point to so long a span of academic appointment and none can claim a more notable record of teaching and professional leadership.

As a teacher, Doctor Myers has been a true friend and inspiration to thousands of students and colleagues. From all corners of the globe, they have come to benefit from his counsel and to partake of the wisdom and experience that he has so generously shared with them. Visitors to the University have beaten a steady path to his door where a cordial welcome was always assured.

But it was not alone as a teacher that Doctor Myers has made his imprint on medicine and on Minnesota. As an independent investigator of the epidemiological aspects of tuberculosis, he has developed concepts which, though bitterly challenged at their inception, have become increasingly accepted as the tuberculosis death rate has declined. A leader in the tuberculosis control pro-

ram in Minnesota, no one has contributed more to the state's enviable record. As the editor of two medical journals and author of several books and of innumerable scientific papers, Doctor Myers has occupied an almost unique position in the field of medical writing and journalism. The light burning in his University office far into the night when other areas were in darkness has given mute testimony to his devotion to these tasks. More local is the praise of patients he has seen in his private office or as consultant to the Student Health Service at the University.

Although Doctor Myers is retiring from the University which he has served so long and so faithfully, he is fortunately not retiring from either academic or professional leadership. As professor emeritus, medical editor, investigator and clinician, his work and his influence will continue. Minnesota owes him a great debt of gratitude for the contributions he has made to its welfare and is fortunate that his academic retirement will only give him more time to devote to his many other medical interests.

CONFESSIONS OF A HOBBYIST

Botanizing

When I was in high school, some fifty years ago, I became interested in identifying wild-flowers, and was encouraged by one of my teachers. He was a very dull Latin teacher, but he had been a pupil of the great botanist, Asa Gray. He knew the plants and the trees, the grasses, sedges, mosses and lichens. When I last saw him, five years ago, he was 102, but as clear-headed as ever, and he presented me with two rare books on mosses. It was he who encouraged me to make an herbarium, and I must have done rather a good job, because, not long ago, the University of Minnesota was glad to get the collection, made in 1900.

Once one becomes conscious of plant growth, there is no boredom any where—even on a dump-heap. Interesting things grow everywhere. I am not a qualified botanist, but I have acquired some knowledge of the characteristics of the various families, and I have had infinite pleasure in seeking and identifying wild plants. For about thirty-five years, I did little active botanizing, and then I was at it again, here in Minnesota. I did some

collecting for the University in Cook County, and found there, among other things, an orchid, *Arethusa*, almost unknown in this state. But pressing and mounting specimens no longer appealed, and color photography gave me the idea of photographing flowers in their natural habitat. A very difficult kind of photography, as I soon discovered, but fascinating. The result has been about 1100 color slides, and from some of the best of these, color prints, of which more later, when I write of photography. Like most amateurs, I was particularly interested in the Orchidaceae, and my collection includes fine photographs of the six *Cypripedia* (Moccasin Flower) that grow in Minnesota. I soon discovered that most of the beautifully illustrated "wild flower books" list only things that are easily identified, and turned to the technicalities of Gray's Manual and Britton and Brown for identifications of less conspicuous plants.

Botanizing is, perhaps, the best hobby of all, because it combines so many things—exploration, photography, a bit of fishing on the side, and the best of outdoors. Mrs. Briggs, who has become as great an enthusiast as I am, and I have prowled all through the National Forest in northern Minnesota, by canoe and on foot. We've penetrated swamps, some of them dangerous, because a swamp may be a botanical treasure-trove. We know the flora of Minnesota and New England pretty well now. Our photographs have been taken in floating bogs in the north, in Minnesota river-bottoms, in the alley behind our house, and in all sorts of unexpected places.

JOHN DEQ. BRIGGS

CALENDAR HISTORY

After the demise of Franklin's almanac in 1757, others sprang up to furnish the early American businessmen and homes with calendars. These ventures continued on until the late 1880's, and some are still being published.

It was during the 19th century that advertising business calendars had their first feeble introduction to the American way of life. Early in the century, almanacs carried advertising, or at least the name of the publisher. In 1836, one published in New York carried an advertisement for pills, and others soon afterward put in a "plug" for vegetable powders and syrups. Vari-

ous New York publications prior to the Civil War added pages of advertising to their annual almanacs, and it looked as if business had at last gotten its foot in the door with calendar advertising, for medicines, cough cures and similar products.

In the 1850's and '60's, a single-sheet business calendar began to appear. These were put out carrying the name of printers, lithographers, engravers and newspaper publishers.

The birth of a calendar as a truly advertising medium for a businessman other than those in the printing or allied fields sprang from the necessity of a couple of broke but resourceful newspaper publishers.

Edmond B. Osborne and Thomas D. Murphy were college chums in the 1880's. Partners after graduation in operating a weekly paper at Red Oak, Iowa, the young men wanted to run a picture in their publication of a projected new courthouse. Unable to pay for a wood cut, since this would use up the entire week's revenue from their paper, Osborne hit on the idea of paying for the cut. He outlined to his partner a plan for printing a wall calendar, surrounding it with advertising of local merchants. About twenty-five businessmen went for the idea, and the young advertising calendar pioneers netted \$300 on the deal. They put out 1,000 calendars.

Their first salesman was Herbert Huse Bigelow, the man who founded the largest calendar house in the world. He teamed up with a printer, Hiram Brown, in 1896 to start the firm of Brown & Bigelow in Saint Paul. Brown left the firm shortly after its organization. Bigelow pumped life into the partnership through emphasis on quality, and after three years enlarged quarters were necessary.

In 1903, the first full-color calendar reproductions were offered customers in a subject called "Luscious Fruit." In 1904, the firm followed with the famous girl subject, "Cosette," which proved a fast-selling item for many years and gave an early forecast of the value of a pretty girl on any type of advertising.

Introduced in these early years were items such as horse covers, cloth caps, pancake turners, fly swatters, watch fobs and similar popular merchandise.

JOSEPH H. SUMMERS

Brown & Bigelow

THE SIZE AND MATERIAL OF BOOKPLATES

In the first article of this series, the antiquity of the bookplate was outlined; in the second, the customs of collecting and exhibiting; in the third, the famous depositories. As to the size of a bookplate, personal choices vary. Some are as small as a postage stamp, the average size being two by three inches. Some are of thin leather, stamped with gold leaf. These are often oval or round and small, from an inch to an inch and a quarter high.

The material of which bookplates are made may vary. It may be a non-curling white paper with a smooth surface and gummed back, or a Japanese vellum, or it may be almost any paper which takes the printing well and which interests the owner. If a gummed paper is used, be sure the quality is excellent. It is not possible to get the more unusual papers already gummed, and it is not satisfactory to have the printer try to gum them and allow them to dry. This curls the paper and often spoils the prints, if they are from a steel engraving, for example. A bookplate is a strong influence to endear to a child its own small library as nothing else can, and even a child can enter a bookplate printed on simple gummed paper. Just help him to get it in straight, for this is one of the rules. It is to go inside the stiff cover, always; at its center, or in one of the corners.

Various methods of making the plate are employed, sometimes lithography, excellent wood-cuts and even linoleum blocks. There are three processes which I am accustomed to use as a designer: zinc etchings, copper plates, and steel engravings. As soon as the metal plate is finished, almost any number of impressions can be taken, from any kind of plate.

The plate by the simplest of these three processes is a zinc etching. This is made from a black and white drawing in ink, black waterproof ink being used, the design being preferably three or four times the size it is to be in the finished plate. The cardboard with the best surface for the drawing is Doeskin. Ten dollars ought to cover the cost of a zinc etching, which is made by a photo-engraver in any city. This plate is mounted on wood. Any printer who uses type can print from this plate. His bill ought not to exceed five dollars

Fourth in a series of editorials on bookplates.

any quantity up to 200. To this, one must add the cost of the paper which will probably be from a dollar up, depending on the kind of paper chosen, perhaps hand made from Sweden, Holland, England, Italy or the Orient.

The second process is a thin copper plate. The engraver cuts directly on the metal with a graver, and a black and white drawing is reproduced on the copper by the photogravure process, known also as intaglio, which is handled only in certain parts of our country. In either event, the process of printing is the same. The material is dampened and allowed to lie between blotters over night. Then the prints are made separately by hand. If more than a few copies are to be made from this plate, it is necessary to have a steel coating floated on the surface. This does not fill in the lines which hold the ink, nor render the plate less effective. In a few cities, there are now specialists who print with paper dry, and by power press, from photogravure plates.

The cost of the plate, if cut by hand by the engraver, depends upon the charges usually asked by that person for his own etchings. If done by the photogravure process, the cost of the plate and its steel facing will be about \$75.00, as compared with the \$10.00 charge for the zinc etching. After the plate is made, the cost of prints is approximately \$15.00 a hundred, including stock, if they are two by three inches, even three by four inches, in size, and are printed from this intaglio or photogravure plate.

ELECTIVE INDUCTION OF LABOR

(Continued from Page 624)

same in both induced and spontaneous deliveries; however, we had only about one-fourth as many stillbirths in those patients induced as in those allowed to go into labor spontaneously.

8. Our stillborn rate and our neonatal death rate was about one-half of the average rates in the State of Minnesota. This might be due to lessening of cases of postmaturity, which is ranked second only to prematurity by some authors as a cause of fetal and neonatal mortality.

9. Though the series presented may be too small to be of great significance, in our experi-

ence induction of labor had no effect upon maternal morbidity.

Conclusions

If certain rigid criteria are fulfilled, in our experience, elective induction of labor shortens the labor and is a safe procedure for the mother and safer for the fetus. There are many other advantages. The patient and her family can prepare for the event. She is scheduled and admitted to the hospital at a time when it is most desirable from the standpoint of hospital administration. We believe elective induction of labor properly carried out, can no longer be classified as radical obstetrics.

OLD AGE PENSIONERS

Lone women apparently are able to fend for themselves much better than men, Dr. R. C. F. Smith concludes from a study of 1,000 old age pensioners in North-east England. There were 500 men and 500 women included in the study who varied in age from 62 to 97 years. Melancholia was almost exclusively a male finding and almost always due to the death of the partner.—*Foreign Letters, J.A.M.A.*, July 20, 1957.

President's Letter

THE AMERICAN MEDICAL EDUCATION FOUNDATION

In 1951, as one means of resisting pressures for government financial aid to medical schools, the American Medical Education Foundation was created. The function of this Foundation is to solicit and distribute funds to medical schools of the United States for teaching and research facilities. As a companion to this organization, there was created the National Fund for Medical Education. Physicians were accorded the privilege of contributing to the former. Funds for the latter came from many sources, primarily from industry and from other foundations.

In 1951, when the American Medical Education Foundation was created, it was felt that the funds of the Foundation would serve as a stimulus to additional contributions from all sources, and so the funds were disbursed through the National Fund for Medical Education. Until 1955, the funds from the American Medical Education Foundation totaled more than half of the amount donated to the schools by the National Fund for Medical Education. Now the funds accruing from other sources have gradually increased, so that the need for the stimulus provided by the Foundation funds no longer exists.

Hence, in 1956, a separate listing and mode of donation of moneys was devised and put into action; the objective was to stimulate physicians to contribute more funds to their own organizations than they might be inclined to do if the contributed funds continued to be received and disbursed by some other organization with which physicians had no intimate association or acquaintance. That is to say, better relationships can be established with contributions by alumni. The American Medical Education Foundation accepts contributions designated for a particular school; the National Fund for Medical Education does not.

The directors of the American Medical Education Foundation, ably led by Dr. Louis H. Bauer, feel that the present direct system of distributing funds will, in the long run, be of greater benefit to the medical schools, and that both the American Medical Education Foundation and the National Fund for Medical Education will be able to raise more money, than if some other system were used. The American Medical Association underwrites all the expenses of the American Medical Education Foundation, including the costs of campaigns for funds and the educational program. The expense for such purposes in 1956 approximated \$118,000. In addition to this, the American Medical Association donated \$343,000 to the American Medical Education Foundation.

On February 11 of this year the American Medical Educational Foundation disbursed its grants to the nation's 83 medical schools. This year's total funds were \$1,072,717. Approximately \$500,000 in designated money was given to the medical schools across the nation.

At the same time that the American Medical Education Foundation distributed its grants, the National Fund for Medical Education also mailed checks to the medical schools. This year the grants included matching moneys from the Ford Foundation, which was of great help. There is probably nothing more important to practicing physicians than the financial support of our medical schools, so that they may remain free. These schools, in turn, feel deeply indebted to the physicians who have generously supported the American Medical Education Foundation and to industry and individuals who have supported the unselfish efforts of the officers and directors of the National Funds for Medical Education. Both organizations must prosper, and we are confident that both will receive your very necessary support.

PRESIDENT'S LETTER

Each state has an outstanding and respected physician who is in charge of the campaign to solicit funds. In Minnesota this post is occupied by Dr. Charles E. Rea of St. Paul. Each county or district medical society has a chairman who solicits funds in your region. It seems hardly apropos to refer to this action as "soliciting," because you as physicians should search out this man in your community and make a generous donation for the betterment of your medical school.

AFL-CIO TO FIGHT MEDICAL SOCIETY ACTIONS

A firm stand against the actions of medical societies who fail to go along with union labor medical programs has been agreed upon by the AFL-CIO committee on social security according to the *Summer Newsletter* issued by the Association of Labor Health Administrators. The ALHA is a group of medical directors, lay administrators and other representatives of union health center plans.

The publication calls for action on opposing the "attack and harassment of component medical societies against union plans, particularly in the states of Pennsylvania, Illinois and Colorado."

It states that at a meeting in Washington in May "at the merged headquarters" the AFL-CIO executive committee approved funds to encourage and promote the work of the ALHA in providing "technical aid to the trade union groups in development of better health service programs for the benefit of workers and their families." The letter also stated that the Association will "stand ready to bring experienced technical and legal counsel on request to the defense of the victims of any efforts on the part of medical power groups to destroy programs which endeavor to improve the quality and scope of prepaid health services available to working people and their families." The work will be carried out in co-operation with AFL-CIO through its department of social security.

The *Newsletter* used terms such as "medical power group", "fee-minded physicians" and "monopolistic elements of organized medicine" in referring to the recent actions taken by medical societies in Pennsylvania, Illinois and Colorado.

FIRST CHECKS FOR THE DISABLED GO TO 100,000

The new type of social security payments to totally disabled people aged fifty to sixty-four has begun. First checks are going out to about 100,000, but the number gaining benefits and the costs are expected to rise rapidly. Already pressure is building up to expand these benefits and to make more workers eligible to receive them.

The first checks, sent out in August, averaged \$75 each. By the end of the government's present fiscal year, next June 30, the total number of awards is expected to reach 275,000 with benefits running between 175 million and 200 million dollars. By the year 1980, it is expected that at least a million people will be getting disability-insurance benefits and that costs will run close to a billion dollars a year—just on the basis of present requirements.

To get these benefits now, an individual must be totally and permanently disabled. He or she must be able to provide "medical proof" that he is unable to engage in "any substantial gainful activity." The disability may prevent him from continuing in his normal occupation, but he still may not qualify if he is able to do another kind of work, even though it pays less than the old job.

The individual has to be disabled for at least six months before applying for benefits and then there must be convincing evidence that the disability is permanent—that later he will not recover enough to return to work. He must have social security credits for five years of work in the ten years before he became disabled and for one and one-half years of work in the three years immediately prior to the disability.

If he qualified then, he can start drawing benefits equal to what his old-age pension would be at age sixty-five—from a minimum of \$30 a month up to \$108.50. He cannot get benefits for his dependents until he reaches 65 and switches to his old-age pension.

Pressure to ease the rules already is building up. There is now a bill before Congress to give benefits to dependents of disabled workers on the same basis as those going to dependents of workers on old-age pensions.

Some members of Congress predict flatly that the minimum age limit of fifty for disability benefits is sure to be removed so that any disabled worker, no matter how young, can get benefits if he has enough social security credits.

Young workers who are disabled argue that a person who is thirty-five—or forty-five—and cannot work needs help as much as someone who is

fty, and maybe more than a worker who is sixty-five but is still able to continue on the job.

It is estimated that, for every sixty disabled workers in the fifty-to-sixty-four age bracket, there are forty more who are under age fifty.

Demands are also being heard for some easing of the present rigid rules on how badly you have to be disabled to get a pension. For one thing, you may be disabled a year, two years, three years and still be refused disability benefits if there is no reasonable indication that later you will recover sufficiently to do some kind of work. Any easing of this rule would undoubtedly bring benefits to many thousands of people now suffering from prolonged illnesses. Carried far enough, it could mean a form of sick pay under social security.

Actual cases where benefits have been granted show that the great majority of people who are unable to work are disabled by chronic diseases rather than by crippling injuries. Among applications for benefits approved so far, for instance, nearly one-third were from workers disabled by heart ailments and diseases of the blood vessels. About one-fourth were disabled by diseases of the nervous system and impaired sight or hearing. One-eighth were suffering from mental disorders.

Most of the people who have been turned down were suffering from similar ailments but it was decided either that they were not disabled enough to prevent them from doing some type of work or that there were indications they would recover enough to return to work later.

GROUP HEALTH FEDERATION MEETS IN TWO HARBORS

The Group Health Federation of America—which recently changed its name from “Co-operative Health Federation”—representing more than a score of prepaid group medicine plans—held its annual meeting in Two Harbors in July.

This group was organized in Two Harbors in 1946. The persons making up the organization for the most part, are members of labor and consumer co-operative groups and social liberals who believe in organizing medical plans to pay groups of doctors to care for them at so much per month. Two of these plans, each started within the past ten years, now cover more than half a million persons apiece.

One is the Health Insurance Plan of Greater New York which operates through thirty-two individual medical groups. The other is the Kaiser-

Permanente Plans on the West Coast. This latter group does not belong to the Group Health Association because it is not consumer operated.

A new plan with similarly huge potential—the Community Health Association of Detroit, Michigan—is planning to go into operation, with the support of the United Auto Workers. President Walter Reuther is in charge of the plan.

The Community Health Center at Two Harbors is a smaller but similar plan. The group's five doctors work in a new clinic dedicated recently by Governor Orville Freeman. The doctors care for 3,400 members and dependents for \$5.00 per month for individuals and \$9.75 for a family of two and \$11.75 for three or more. This covers both medical care and basic hospitalization in another new Two Harbors institution, Lake View Memorial Hospital, next to the co-operative clinic.

Group Health of St. Paul, which dedicated its \$800,000 home office and medical center at 2500 Como Avenue in March, like Two Harbors, will sign up members for combined medical-hospital benefits. Individuals will pay \$7.50 a month; couples, \$14.50; families, \$20.75. For this sum, the members are to get: (1) medical and surgical care, including periodic checkups and necessary shots; (2) \$15 a day for 180 days for a hospital room plus other hospital benefits.

Plan members in Two Harbors get home calls for an extra \$2.00. The St. Paul plan will charge an extra \$3.00 between 7 a.m. and 7 p.m. and \$5.00 after 7 p.m.

The St. Paul plan permits its members to choose either care at its medical center or a cash-benefit policy to use in going to any physician. The big new Detroit plan is expected to have the same provision.

STATISTICS REVEALED ON COST OF PRESCRIPTIONS

According to a recent annual report of the Department of Commerce, per capita expenditures for drugs was \$10.12 as compared to \$55 for alcoholic beverages, \$32 for tobacco products and \$18 for the repair, maintenance and parking of automobiles. Out of the \$10.12 drug bill, \$6.43 went for prescriptions.

The Journal of the American Medical Association says that “the price index for prescriptions in 1954 was 115.8 as compared with an index of 114.8 for all consumer goods and services.”

And drug costs were lower than the 1.25 index embracing the sub-indexes which make up the cost of all medical care.

Quoting an audit of 200,000 prescriptions filled in 200 drug stores from coast to coast, the *Journal A.M.A.* reports an average prescription price of \$2.51. Another survey, conducted by a team from the Brooklyn College of Pharmacy, placed the average cost even lower, at \$2.36 with one-half costing \$1.41 or less and only 6 per cent more than \$5.00. The Medimetric Institute, Inc., says the current average price is \$2.27.

AMA ANNOUNCES ADMINISTRATIVE CHANGES; ORGANIZATION OF NEW COMMITTEE

The AMA recently announced two important changes in its administrative setup.

The Board of Trustees has elevated Dr. George F. Lull of Chicago, who has been secretary-general manager of the Association for eleven years, to the newly created position of assistant to the president of the AMA. He will continue serving as secretary.

At the same time, the Board announced the appointment of Dr. F. J. L. Blasingame of Wharton, Texas, to the position of general manager of the AMA. He will take over his new duties on January 1, 1958.

In his new job, Dr. Lull will relieve the president of the Association of many of the burdens of the office, which have become especially heavy in the last few years.

New Committee

A new committee on industrial nursing has been established by the AMA's Council on Industrial Health. The committee was created to provide a "medical-nursing forum" for the consideration of problems of mutual concern. The group will meet this month in New York City.

NATIONAL MEDICAL LIBRARY SELECTS ARCHITECTS

The National Library of Medicine has moved a step closer to realization. The long sought goal—a new structure to house its valuable collection of medical literature—may soon become a reality.

Architects have been elected to complete plans for this project. They are R. B. O'Connor and W. H. Kilhman, Jr., of New York City.

Library officials are hopeful of getting their first construction money next year and are talking in

terms of nine million dollars. Before construction is begun, however, the Presidential ban on new construction by federal agencies will have to be lifted or modified.

CHIROPODISTS BIDDING FOR GREATER RECOGNITION

The organized profession of chiropody is currently engaged in a two-front campaign for Federal recognition. The Ohio Chiropodists Association has lodged a protest with the Public Health Service because the national health survey currently under way makes no allowance for foot services performed by holders of D.S.C. degrees. And the National Association of Chiropodists, headquartered in Washington, is attempting to gain recognition for its members in connection with legislative salary increases for professional personnel in the medical department of the Veterans Administration.

In reply to the protest by the OCA, Dr. Charles E. Greiner, the PHS is expected to explain that chiropody services will be reckoned with in *special* studies to be conducted later as part of the national health survey authorized by Congress.

FTC TO QUESTION EIGHTEEN FIRMS ON ANTIBIOTICS PROFITS

The Federal Trade Commission will direct the nation's 18 manufacturers of antibiotics to answer a lengthy questionnaire and give detailed information on sales volume, costs, classification of employers, pricing policy and profits. FTC last year distributed a questionnaire among manufacturers to gather data on patients, discount schedules and certain other business angles. The new one, however, will probe more intimately and deeply into the companies' operation.

Openly expressed suspicion by a few members of Congress that too fat profits were being made by "miracle drug" producers resulted in this FTC investigation which has been dragging on for about two years.

"SICK PAY" MAKES LOST TIME ALMOST PROFITABLE

Thanks to a combination of company sick pay policies, medical insurance and the tax laws, an industrial worker may make more money nursing a broken leg than he would on the job.

If his employer, like many today, retains him on the regular payroll despite the absence, up to

(Continued on Page 664)

Editor's Annual Report

MINNESOTA MEDICINE, the scientific standard bearer of the physicians of Minnesota, was printed in nearly 50,000 copies during 1956. The 152 original scientific articles were written primarily by Minnesota's medical authorities. Aiding these authors in the professional and business aspects of advancing medical knowledge is a remarkably large number of individuals who contributed many hours of work and thought to the success of our journal. Among the latter are the members of the Board of Editors. This group expended most of its efforts in the fields of procurement and editing of manuscripts. At its bimonthly meetings a free and active interchange of ideas on all aspects of medical journalism was the order of business. Of greatest interest in this area of their accomplishments was the Reader-Interest Survey conducted at the annual meeting, and the development of a new cover page for the journal.

This report will contain (1) a few statistics and comments concerning the field of procurement and editing; (2) brief references to the Reader-Interest Survey; and (3) recommendations for future changes in the journal and its management.

Procurement and Editing

Of the 1,552 printed pages in the volume of 1956, there were 935 reading pages devoted to the science and business matters of medicine, and 617 pages devoted to advertising. The reading pages have been divided according to Table I and the gross variety of scientific articles is demonstrated in Table II.

The majority of the scientific manuscripts were obtained by a selection of subjects and later manuscripts presented at the medical meetings of special medical societies in the state of Minnesota. The growing co-operation and support of our state medical journal by the various medical societies, the University Medical School, the Mayo Clinic, and the physicians throughout the state has reached a new height during the year. One county society offered an additional \$50.00 honorarium to the speakers at their meetings whose manuscripts were published in MINNESOTA MEDICINE. Another contributed the scientific articles of an entire issue. This growing spirit of enthusiasm and pride in our journal points to an ever-increasing value of MINNESOTA MEDICINE to the physicians of the state. A review of the published titles

Reader-Interest Survey

A poll was conducted by the research division of the School of Journalism of the University of Minnesota under the direction of Dr. Ralph D. Casey and Mr. Jack B. Haskins at the time of the annual meeting in Rochester. It was paid for out of the funds of the Board of Editors. The results have been published previously in our journal. The reading frequency of MINNESOTA MEDICINE was greater than that of the *Journal of the American Medical Association* in spite of the greater availability of the latter journal. No other ethical scientific publication ranked with these two in the interest of Minnesota's physicians. The most popular sections of the journal are, in order: table of contents, regular scientific articles, editorials, general interest and reports, and announcements. Of great importance to the Board of Editors was the demand for articles with immediate clinical application, as opposed to articles of a more fundamental and scientific nature. More articles of a short, succinct, review-type nature—the shorter the better were in demand. A complete review of the results and interpretations of this survey is attached to this annual report.

Recommendations for the Future

A number of defects in our journal are apparent to the Editor. It is hoped that the future

will see the section, "Current Concepts," grow in size and importance. These brief clinically applicable educational reviews are what many physicians have requested. An organized approach to the basic principles of psychology and psychiatry should be developed under the section of "Current Concepts." At present there is a shortage of editorials on subjects of political and economic policy. This may reflect the present caution evidenced by the physicians of the state in these fields. Summaries of the accomplishments of certain important committees should be available in each issue in the section. "Committee Action."

The use of an editorial comment restricted to one or two sentences, and published in italics, would not only make an attractive style when placed in the headings of our scientific manuscripts, but would draw reader interest. The almost continuous late publication of each monthly issue through the year is unnecessarily injurious to the advertisers of pharmaceuticals, and to the readers of our publication. A more legible and psychologically pleasing style of print should be used by our publisher. In spite of the fact that Volume 39 (1956) was published with a profit to the Association, a more realistic monetary value should be placed on MINNESOTA MEDICINE. The present charge of \$3.00 per year has existed since the journal was first published.* A change in the financial bookkeeping without increasing costs to the Society would increase the apparent value to its potential readers.

One recommendation concerning the Publishing and Financing Committee of MINNESOTA MEDICINE has been deleted from this report by order of the House of Delegates, upon recommendation of the Reference Committee.

A. H. WELLS, M.D., *Editor*

*The subscription rate was increased to \$5.00 for non-members, effective January 1, 1957.

RESEARCH ATTACK ON SARCOIDOSIS

The first co-operative research attack on a mysterious tuberculosis-like disease called sarcoidosis is now being conducted by the Veterans Administration.

The five VA hospitals which began a study in May, 1957, to learn the cause and nature of sarcoidosis so steps can be taken to prevent and treat it, are located at Atlanta, Georgia; Dallas, Texas; Madison, Wisconsin; New York City, and Washington, D. C.

A doctor at each of the five hospitals volunteered to study patients with sarcoidosis, not only clinically but with equal emphasis on factors such as environment, occupation, eating habits, and self-medication, which may furnish a lead to solving the cause of the disease.

Sarcoidosis is a more severe and much more widespread disease than has been believed, a preliminary study made by a four-man medical team from VA central office in Washington, D. C., shows. It occurs most frequently in

persons between twenty and forty years of age and produces symptoms often confused with tuberculosis, fungus diseases, and cancer. The growths or nodules characteristic of sarcoidosis usually occur in the lungs but can occur in any organ of the body.

The VA central office research team is made up of Dr. M. M. Cummings, director of research service; Dr. Edward Dunner, secretary of the VA-armed forces committee on chemotherapy of tuberculosis; Dr. R. H. Schmidt, Jr., tuberculosis service; and J. H. Williams of research statistics.

The four have been investigating sarcoidosis since 1954. Their study indicates sarcoidosis sometimes becomes a severe disabling disease and causes death in a larger number of patients than heretofore suspected. They find sarcoidosis occurs in a wide area, especially the New England, North Central, and Southeastern States. They suggest a possible correlation between distribution of the disease and some aspect of the United States pine forest environment.

Their study involves 1,700 cases of sarcoidosis diagnosed in VA hospitals between 1949 and 1956. The age, race, sex, occupation, place of birth, and place of initial hospitalization were recorded for each case. The highest rates of hospitalization for white veterans are among those born in Connecticut, Rhode Island, Georgia, Arkansas, North Dakota, Minnesota, Massachusetts, Alabama, Maine, and Virginia. The highest rates of hospitalization for Negro veterans are among those born in the Southeastern States. However, more Negro veterans than white were victims of the disease for the period of the survey. The Negro veteran hospitalization rate was 40.1 per 100,000, contrasted with 3.3 per 100,000 for white veterans.

The VA medical team said another finding of their study is that nearly all cases came from the non-arid sections of the country and that the prevalence of sarcoidosis is much higher in rural communities than in cities.

"SICK PAY" MAKES LOST TIME ALMOST PROFITABLE

(Continued from Page 662)

\$100 weekly of his salary becomes tax-exempt after the first week. And if medical insurance—company or personal—is sufficient to pay physician and hospital bills, he may well end up with more take-home pay than his colleagues who never miss a day's work.

Most employers don't worry about long-term illness; it is the repeated one-shot absences, a day or so each in duration, that are a bigger headache.

Despite all the advantages that can accrue to a man sick in bed, however, many companies actually believe man-hour losses from illnesses are dropping. They give the credit for this fact to new and relatively firm policies of policing absences.

Meetings and Announcements

STATE

MINNESOTA STATE MEDICAL ASSOCIATION, 105th annual meeting, Minneapolis, May 22, 23 and 24, 1958. Business sessions and exhibits, Minneapolis Auditorium. Headquarters, Leamington Hotel.

NATIONAL

American College of Chest Physicians, Postgraduate Courses on Diseases of the Chest, Knickerbocker Hotel, Chicago, Illinois, October 21-25, 1957; Park-Sheraton Hotel, New York, New York, November 11-15, 1957; and Ambassador Hotel, Los Angeles, California, December 9-13, 1957. Tuition \$75. Executive Director, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

American College of Gastroenterology, 22nd annual convention, The Somerset, Boston, Massachusetts, October 21, 22, 23, 1957.

American College of Physicians, Midwest regional meeting, Urbana, Illinois, October 12, 1957.

American College of Surgeons, Forty-third Annual Clinical Congress, Atlantic City, New Jersey, October 14-18, 1957. American College of Surgeons, 40 East Erie Street, Chicago 11, Illinois.

American Gastroenterological Association, 59th annual meeting, Washington, D. C., May 30-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

Ninth Postgraduate Assembly in Endocrinology and Metabolism, Medical College of Georgia, October 21-25, 1957.

Symposium on Fluorides, Institute of Industrial Health, College of Medicine, University of Cincinnati, Cincinnati, Ohio, December 9-11, 1957. Secretary, Institute of Industrial Health, Kettering Laboratory, Eden and Bethesda Avenues, Cincinnati 19, Ohio.

INTERNATIONAL

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. Dejardin, 141 rue Belliard, Brussels, Belgium.

Fifth International Congress of Internal Medicine, Philadelphia, Pennsylvania, April 24-26, 1958. Edward R. Loveland, Secretary-General, 4200 Pine Street, Philadelphia 4, Pennsylvania.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22, 1957. Executive Director, Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

Pan American Congress of Endocrinology, Buenos Aires, Argentina, November 3-9, 1957. Secretaria-General, Sociedad Argentina de Endocrinología y Metabolismos, Sante Fe 1171, Buenos Aires, Argentina.

Pan-Pacific Surgical Association, Seventh Congress, Honolulu, Hawaii, November 14-22, 1957. Dr. F. J. Pinkerton, Director General, Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, T. H.

World Congress of Gastroenterology, Washington, D. C., May 25-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

ACADEMY OF PSYCHOSOMATIC MEDICINE

The fourth annual meeting of The Academy of Psychosomatic Medicine will be held October 17-19, 1957, at the Morrison Hotel in Chicago. The program will be devoted to "Psychosomatic Aspects of Obstetrics, Gynecology, Endocrinology and Diseases of Metabolism." Sessions will be open to all scientific disciplines, as well as psychologists, social workers and nurses. Information may be obtained from Dr. William S. Kroger, secretary, 104 South Michigan Avenue, Chicago 3, Ill.

AMERICAN MEDICAL ASSOCIATION

The American Medical Association has announced two important changes in its administrative setup.

The Board of Trustees has elevated Dr. George F. Lull, who has been secretary-general manager of the Association for eleven years, to the newly-created position of assistant to the president of the AMA. He will continue serving as secretary, which is an elective office.

At the same time, the Board announced the appointment of Dr. F. J. L. Blasingame of Wharton, Texas, to the position of general manager of the AMA. He will take over his new duties January 1, 1958.

Dr. Blasingame has been active in medical affairs, both at the state and national level for many years. He has been a member of the Board of Trustees since 1949 and has served as president of the Texas State Medical Association.

SYMPOSIUM ON RADIOISOTOPES

The Milwaukee Academy of Medicine will present a symposium on radioisotopes at Marquette University, Brooks Memorial Union, Saturday, December 7, 1957, from 9:00 a.m. to 4:00 p.m. Fundamental information with medical orientation will be presented, and all physicians are invited to attend. The program includes: "Basic Cellular and Histologic Changes Produced by Radiation Energy" by Dr. William Bloom, professor of anatomy, University of Chicago; "Radioisotope Chemistry" by Dr. Edward A. Doisy, Jr., associate professor of internal medicine, St. Louis University School of Medicine; "Basic Nuclear Physics and Instruments" by Titus C. Evans, Ph. D., professor of radiation research,

MEETINGS AND ANNOUNCEMENTS

State University of Iowa College of Medicine; "Radioisotope Pharmacology" by Dr. E. M. K. Geiling, professor of pharmacology, University of Chicago; "Basic Radiation Biology" by Harvey M. Patt, Ph. D., senior physiologist, Argonne National Laboratory; and "Radioisotope Physiology" by Dr. Joseph F. Ross, professor of medicine and associate dean, University of California School of Medicine. Dr. Austin M. Brues, director, biology division, Argonne National Laboratory, will serve as moderator.

Reservations may be made by writing the Milwaukee Academy of Medicine 561 N. 15th Street, Milwaukee 3, Wisconsin.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, include the following:

October	7- 9	Obstetrics for General Physicians
October	24-26	Symposium on Skin Cancer for Specialists
November	4- 9	Cardiovascular Radiology for Specialists
November	18-20	Physical Medicine for Specialists

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

MINNESOTA MEDICAL FOUNDATION DAY

Minnesota Medical Foundation Day will be Monday, September 30. Guest speaker will be Dr. Dana W. Atchley, Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons and Visiting Physician, Presbyterian Hospital, New York City, who for many years has combined a very active private practice with a career as a teacher and investigator. Dr. Atchley will speak at 11:00 a.m. in the Mayo Memorial Auditorium on the University of Minnesota Campus. All physicians are cordially invited to attend.

SYMPOSIUM ON RECENT DEVELOPMENT IN DIABETES MELLITUS

An all-day symposium on "Recent Developments in Diabetes Mellitus" (pathology diagnosis and therapy) will be sponsored by the Chicago Diabetes Association, November 20, 1957, at the Drake Hotel, Chicago. Registration is scheduled for 8:45 a.m. and lectures will begin at 9. An enrollment fee of \$25.00 will be charged.

Members of the Academy of General Practice who attend the conference may claim hour-for-hour Category II credit.

Henry T. Ricketts, M.D., Professor of Medicine, University of Chicago Clinics, will be Moderator, and the following program will be presented:

Pathology of Diabetes Mellitus in Man—Aaron Arkin, M.D., Chief of Medicine, Louis A. Weiss Memorial Hospital; Professor of Medicine, University of Illinois College of Medicine and Cook County Hospital Graduate School of Medicine, Chicago.

Metabolic Derangements in Diabetes Mellitus—Rach-

miel Levine, M.D., Chairman, Department of Medicine, Michael Reese Hospital, Chicago.

The Metabolism of I¹³¹ Labeled Insulin—Solomon A. Berson, M.D., and Rosalyn S. Yalow, M.D., Chief and Assistant Chief, Radioisotope Service, Veterans Administration Hospital, New York.

Insulin Resistance—Arthur R. Colwell, M.D., Professor of Medicine and Chairman, Department of Medicine, Northwestern University Medical School, Chicago.

Oral Hypoglycemic Agents in the Treatment of Diabetes—Alexander Marble, M.D., Joslin Clinic, Professor of Medicine, Harvard Medical School, Boston.

Current Concepts of the Pathogenesis of Diabetic Retinopathy—David A. Rosen, M.D., Department of Ophthalmology, Kingston General Hospital, Kingston, Ontario.

Diabetic Nephropathy—Robert M. Kark, M.D., Professor of Medicine, University of Illinois College of Medicine, Chicago.

Juvenile Diabetes—Howard S. Traisman, M.D., Children's Memorial Hospital; Associate in Pediatrics, Northwestern University Medical School.

MINNESOTA HEART ASSOCIATION

Dr. Milton M. Hurwitz, St. Paul cardiologist, was elected president of the Minnesota Heart Association, at the annual meeting in St. Paul in July. Dr. Karl W. Anderson, Minneapolis, was named first vice president, and Dr. Robert A. Good, University of Minnesota, was elected secretary.

The Association approved \$201,000 in local research awards for 1957-58. Grants from the American Heart Association to Minnesota scientists will bring total Heart Fund research spending in Minnesota to \$317,732 during the next twelve months. Sixty-three men will share the awards.

The Minnesota Heart Association this year noted its tenth Anniversary. Since 1947, it has distributed over \$1.1 million in research awards, allocated from Heart Fund contributions of \$2.2 million.

TWO FELLOWSHIPS TO RECRUIT WORKERS IN AUDIOLOGY AND SPEECH

Establishment of two fellowships in Audiology and Speech at Northwestern University is announced by the American Hearing Society, its member agency, the St. Paul Hearing Society, and the university. The new training program will be geared to preparing qualified persons for work in local hearing societies.

The fellowships, made possible by a bequest from the Myers Foundation of Saint Paul, Minnesota, are to be known as The Reine Humbird Myers Fellowships. Each fellowship will pay \$3,000 a year for two years.

Applicants may write to Crayton Walker, executive director, American Hearing Society, 1800 H St., N.W., Washington 6, D. C., or to Dr. Raymond Carhart, School of Speech, Northwestern University, Evanston, Illinois.

Woman's Auxiliary

AMA AUXILIARY PRESIDENT, AND DOCTOR ALVAREZ TO ADDRESS SCHOOL OF INSTRUCTION

The annual School of Instruction for all state and county officers of the Woman's Auxiliary to the Minnesota State Medical Association will be held at the Hotel Leamington in Minneapolis, Tuesday, October 8.

Following the program will be Mrs. Paul C. Craig of Wyomissing, Pennsylvania, president of the Woman's Auxiliary to the American Medical Association, and Dr. Walter Alvarez, nationally-known newspaper columnist and editor-in-chief of *Modern Medicine*.

An attendance of approximately 100 is expected at the day-long session and luncheon. Reservation blanks will be sent to all state officers, state committee chairmen and county presidents, but any Auxiliary member is cordially invited to attend. Reservations for the luncheon may be obtained by contacting Mrs. Edward T. Evans, 5308 Blake Road, Minneapolis, 24, Minnesota.

An outstanding program of instruction has been planned, with the county officer particularly in mind. Mrs. Craig will be in attendance at the sessions in addition to speaking before the group.

Mrs. Craig is a graduate of West Virginia University, took post-graduate work at Columbia University, and had a dietetic internship at Presbyterian Hospital in New York before her marriage to a Reading, Pennsylvania, ophthalmologist. In addition to her medical auxiliary work, she has served on the boards of the YWCA, the PTA, the Historical Society of Berks County, the Council of Social Agencies and has been president of the Reading Branch of the American Association of

INTRODUCING THE NEW STATE PRESIDENT-ELECT

Mrs. Reuben Erickson, president-elect of the Woman's Auxiliary to the Minnesota State Medical Association, comes into her work in the medical field naturally because of the zest of her husband, whose record of public leadership has been well shown in the many offices he has held, both medically and politically.

Better known as "Hazel" Erickson, the new president-elect, is a native of Minneapolis. She graduated from the University of Minnesota and taught at Roosevelt High School in Minneapolis both before and after her marriage, while her husband finished his medical education and set up his practice.

Hazel has held just about every office in the Hennepin County Medical Auxiliary, covering a period of about twenty-eight years. She has been on the state board, on and off, for the last sixteen years.

Both of her children are following the line of medicine; her daughter, Patty, is in her senior year at the University of Minnesota in occupational therapy and her son, Hartley, is in his third year of premedicine at the University.

Mrs. Erickson's special interests and activities center around Mount Olivet Lutheran Church in Minneapolis and the Minneapolis Church Council. This past summer, she has been busy helping to entertain the overseas guests attending the Lutheran World Federation which met in Minneapolis.

Another pet project has been her work with senior citizens. She helped to organize the first hobby show for senior citizens in Minneapolis and later became chairman of the show. She is now a member of the board of the Council House for Senior Citizens. Last year, this energetic worker suggested that the Hennepin County Medical Auxiliary help the Council House by sponsoring a sale of articles made through the handicraft of senior citizens. Under her direction, the sale was held at Donaldson's in Minneapolis and was very successful. The Hennepin Auxiliary will sponsor a similar sale this coming year.

Hazel Erickson's love of people and her desire to promote good feeling among people will be a sure asset towards a very fine public relationship between the physicians and lay groups—the aim of every auxiliary unit in Minnesota.

MEMORIAL SERVICES CONDUCTED FOR DECEASED MEMBERS

A portion of both the state auxiliary meeting in St. Paul in May and the national auxiliary meeting in New York in June was devoted to memorial services for Auxiliary members who have died during the past year. A particularly lovely service was given by Mrs. Charles Waas, In Memoriam chairman, at the state meeting in St. Paul. The following Minnesota members were honored at both services.

Mrs. E. J. Wohlrabe, Springfield
Mrs. Magnus Westby, Madison
Mrs. John R. Peterson, Minneapolis
Mrs. Edwin N. Nelson, Minneapolis
Mrs. Nathan K. Jensen, Minneapolis
Mrs. George Eitel, Minneapolis
Mrs. A. Carlyle Tingdale, Hibbing
Mrs. Alvin Westerman, Montgomery
Mrs. Ludwig L. Sogge, Windom
Mrs. George Badeaux, Brainerd
Mrs. Haddow M. Keith, Rochester

SPORTS DURING PREGNANCY

Women during uncomplicated pregnancy may participate safely in any common sports in which they are proficient. An experienced swimmer may safely swim while pregnant, an expert horsewoman may ride (but not jump), a good skater may skate. If a woman plays tennis, she should play doubles, and if she bowls, she should play only a few games at a time. Practically all women may dance but "preferably not the dances which demand frequent sudden gyrations."—Queries and Minor Notes, *J.A.M.A.*, July 13, 1957.

In Memoriam

PAUL E. BARRINGER

Dr. Paul E. Barringer, practicing physician in St. Cloud, Madison Lake, and St. Paul for many years, died June 30, 1957, in Brooklyn, New York. He was seventy-one years old.

A graduate of the Minneapolis College of Physicians and Surgeons, Dr. Barringer took postgraduate work in Europe and practiced in St. Paul from 1908 to 1926. He moved to Madison Lake in 1926 and stayed there until he settled in St. Cloud in 1936. He had lived in Long Island, New York, until his retirement in 1949. He served in the merchant marine during World War II.

Dr. Barringer had belonged to the Ramsey County Medical Society, the Stearns-Benton County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by a son, Paul, Minneapolis; a daughter, Mrs. Shirley Hamburg, Long Island, and five grandchildren.

MANDRED W. COMFORT

Dr. M. W. Comfort, a member of the Mayo Clinic staff since 1928, died August 7, 1957. He was sixty-two years old.

Dr. Comfort was born in Hillsboro, Texas, attended Austin College, Sherman, Texas, and received his medical education at the University of Texas in Galveston. He was adjunct professor of anatomy at the University of Texas and later took postgraduate work in neurology at the Mayo Foundation in Rochester.

Dr. Comfort specialized in diseases of the stomach and intestines.

He was a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association, the American Medical Association, the American College of Physicians, the Southern Minnesota Medical Association, the Central Society for Clinical Research, the American Gastro-enterological Association, the Alumni Association of the Mayo Foundation, and an honorary member of the Hill County (Texas) Medical Society. He also held membership in Alpha Kappa Kappa, Alpha Omega Alpha and Sigma Xi fraternities.

JOHN M. CULLIGAN

Dr. John M. Culligan, St. Paul surgeon for thirty-two years, died August 7, 1957. He was sixty-two years old.

At the time of his death, he was chief of the surgical staff at Ancker Hospital, St. Paul, and consulting physician for the Little Sisters of the Poor.

Dr. Culligan was born in Yankton, South Dakota, attended St. Thomas Academy and College, St. Paul, Notre Dame University and the University of Minnesota Medical School, from which he graduated in 1920. After winning a fellowship from the Mayo Foundation to complete his Master of Science work, he entered private practice in St. Paul in 1925.

He was a member of the American College of Sur-

geons, the Minnesota State Medical Association, the American Medical Association, the American Urological Association and the Minnesota Academy of Medicine. Dr. Culligan was also a past president of the Ramsey County Medical Society and the St. Paul Surgical Society.

Other memberships included the Advisory Board of the Association of Residents and Ex-Residents of the Mayo Clinic and the Board of Athletics at Notre Dame University. He was also a former chief of staff at St. Joseph's Hospital, St. Paul.

Surviving are his wife, Margaret; four sons, Dr. John A., Robert E., David E., and F. Joseph Culligan, all of St. Paul; two daughters, Mrs. Molly Olin, Minneapolis, and Margaret Culligan, St. Paul; five grandchildren; two brothers, Emmett J. Culligan, San Bernardino, California, and Dr. Leo C. Culligan, Minneapolis, and a sister, Anne V. Culligan, Minneapolis.

HOWARD L. EDER

Dr. Howard L. Eder, a former Minneapolis physician, died in July, 1957, in Santa Barbara, California. He was sixty years old.

Dr. Eder was born in Blue Earth, Minnesota and graduated from the University of Minnesota Medical School in 1922. After completing his internship, he studied pediatrics in Berlin and Vienna. He practiced medicine in Minneapolis until 1929 when he moved to Santa Barbara.

He was a member of the Minneapolis Athletic Club and the Gyro Club of Minneapolis. He also was a charter member of both the American Academy of Pediatrics and the American Board of Pediatrics.

Survivors include his wife, Margaret; two daughters: Patricia, Santa Barbara, and Mrs. Wynne C. Smallwood, Berkeley, California; three brothers: Walter, Blue Earth; Edward, Excelsior, Minn., and William, North Branch, Minn.; two sisters: Mrs. Arlo Sillman, Everett, Washington, and Mrs. John Rogers, Minneapolis; his step-mother, Mrs. August Eder, Santa Barbara, and a step-sister, Mrs. Robert Path, Santa Barbara.

OLE J. GRUNDSET

Dr. Ole J. Grundset died June 30, 1957. He had been located in Montrose, Minnesota, since 1932. He was seventy years old.

Dr. Grundset was born near Barnesville, Minnesota, and attended Maplewood Academy at Hutchinson, Minnesota, Union College, Lincoln, Nebraska, and received his medical education at the College of Medical Evangelists, Los Angeles, California.

After his internship at White Memorial Hospital in Los Angeles, he practiced in Imperial County, California, and in Excelsior, Minnesota, before moving to Montrose. He and his wife also spent eight years in

RELIEVES THE GNAWING ACHE

Pro-Banthine® provides rapid control of pain in peptic ulcer

In a two-year study¹ by Lichstein and co-workers, documented by intensive personal observation and by follow-up studies, Pro-Banthine (brand of propantheline bromide) often brought immediate relief of ulcer pain. Patients (11 per cent) who did not respond satisfactorily to Pro-Banthine therapy had "anxiety manifestations of psychoneurotic proportions."

In addition to frequent immediate symptomatic relief, Pro-Banthine reduces gastrointestinal motility and diminishes the secretion and acidity of gastric juice, all-important factors in the generation and aggravation of peptic ulcer.

These actions of Pro-Banthine and its demonstrated effectiveness in accelerating ul-

cer healing²⁻⁵ mark the drug as a most valuable adjunct in the treatment of peptic ulcer.

The suggested initial dosage is one 15-mg. tablet with meals and two tablets at bedtime. An increased dosage may be necessary for severe manifestations and then two or more tablets four times a day may be prescribed.

V¹⁰ protein

is a
COMPLETE PROTEIN

*Complete protein
is essential to
the maintenance
of body cells*

Constant daily replacement of protein forming the cells of blood, skin, muscle, nerve, bone, and even teeth, is necessary to maintain health and vigor. In order that this process be maintained, the diet must contain adequate quantities of "complete protein" with all of the essential amino acids for simultaneous ingestion.

The Wisconsin Alumni Research Foundation has licensed the production of such a complete protein in the form of V¹⁰ Protein Concentrate. V¹⁰ Protein is composed entirely of grains, yet results of laboratory tests by the Foundation show that it has a protein efficiency value equal to casein, the high quality protein standard commonly used in protein evaluation work.*

Now V¹⁰ Protein is available in Minnesota in V¹⁰ Protein Bread. This light, delicious bread adds variety to the daily dietary requirement for protein. V¹⁰ Protein Bread will greatly aid in the planning of meals and will help promote health and vigor for all age groups.

Manchuria in mission service. Mrs. Grundset preceded the doctor in death in 1950.

A member of the Wright County Medical Society, Dr. Grundset also belonged to the Minnesota State Medical Association.

He is survived by two daughters: Ruby Grundset Drahosh, Pine City, and Pearl, Montrose; three sisters: Mrs. Ina Hendrickson, Estacada, Oregon; Mrs. Oscar Shulstad, Barnesville, Minnesota, and Mrs. Oscar Vixie, Milton-Freewater, Oregon; two brothers: Anol, Loma Linda, California, and Henry. Arpin, Wisconsin, and several nieces and nephews.

OSCAR C. HEYERDALE

Dr. Oscar C. Heyerdale, retired assistant superintendent of the Rochester State Hospital, died July 20, 1957. He was eighty-four years old.

Dr. Heyerdale was born in La Crosse, Wisconsin, and received his medical education at Northwestern University. He was assistant physician at the Rochester State Hospital from 1899 to 1912, when he became assistant medical superintendent, a position he held for thirty-eight years until his retirement in 1937.

The oldest past master of the Rochester Masonic Lodge, he was also a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by six grandchildren. His wife, a son and a daughter all preceded him in death.

HOBART C. JOHNSON

Dr. Hobart C. Johnson, nationally-known Mankato eye specialist, died July 23, 1957, in Duluth, Minnesota. He was sixty years old.

Dr. Johnson, who had practiced in North Mankato for twenty years, was known throughout the United States for his work in the treatment of diseases of the eye and eye surgery.

A native of Olfburg, Kansas, he graduated from Gustavus Adolphus College, St. Peter, Minnesota, and received his medical education at the University of Minnesota. He later served on the board of trustees at Gustavus and was honored at the graduation exercises of the college last year with the "Greater Gustavus" award, which is given annually to an individual who has done outstanding work for the college.

He took postgraduate work at the New York Postgraduate Hospital and School in New York City. Before moving to Mankato, he served as a medical missionary in Africa from 1928 to 1938. In preparation for this assignment, he took work in tropical medicine in England and became a member of the Royal Society of Tropical Medicine.

Dr. Johnson was a staff member of both Immanuel and St. Joseph's Hospitals in Mankato, a deacon of the Grace Lutheran church, and a member of the Nicollet-Le Sueur Medical Society, the Minnesota State Medical

Association and the American Medical Association. He served as secretary-treasurer of the county society for three years. He was also a member of the Minnesota Academy of Ophthalmology.

He is survived by his wife, Ruth; two daughters, Mrs. Russell Knutson, Fort Smith, Arkansas, and Dorothy, Mankato; one son, Wendell, Duluth; his mother, Mrs. A. G. Johnson, Mankato, and two grandchildren.

JOHN E. OSBORN

Dr. John E. Osborn, Rochester, Mayo Clinic staff member, died July 30, 1957. He was thirty-eight years old.

Dr. Osborn was born in Wolcott, New York, attended the University of Notre Dame and Syracuse University and received his medical education at the University of Buffalo. He interned at Rochester General Hospital, Rochester, New York, and moved to Rochester in 1944 as a fellow in anesthesiology. He served with the Army Medical Corps from 1946 to 1948 and on January 1, 1949, was appointed to the staff of the Mayo Clinic. The same year he was certified as a specialist in anesthesiology by the American Board of Anesthesiology, Inc. In 1956, he was appointed an instructor in anesthesiology in the Mayo Foundation.

A member of the Zumbro Valley Medical Society, Dr.

Osborn also belonged to the Minnesota State Medical Association and the American Medical Association. His other memberships included the American Society of Anesthesiologists, the International Anesthesia Research Society, the Alumni Association of the Mayo Foundation, the American College of Anesthesiologists and the International College of Anesthetists. He also belonged to the Minnesota Society of Anesthesiologists, Alpha Chi Sigma, professional chemical fraternity, and Nu Sigma Nu, professional medical fraternity. He was an honorary member of the Cuban Society of Anesthesiologists.

Survivors include his wife, Agnes; four children, Michael, twelve; Stephen, nine; Mary, six and Julianne, five weeks; his parents, Mr. and Mrs. Homer S. Osborn, Wolcott, New York, and a brother, Stewart, Shreveport, Louisiana.

GEORGE E. SHERWOOD

Dr. George E. Sherwood, who practiced medicine in Kimball, Minnesota, for nearly sixty years, died in St. Cloud, July 5, 1957. He was eighty-five years of age and was known as "Minnesota's oldest practicing physician."

A graduate of the University of Minnesota Medical School, Dr. Sherwood was recently honored by St. Joseph's Hospital in St. Paul as the only physician of that institution's first intern class. He was there from 1893 to 1894 and in October, 1894, opened an office at

GEORGE E. SHERWOOD

(Continued from Page A-48)

Dassel where he practiced until 1900 when he moved to Kimball.

Dr. Sherwood established the first hospital in Meeker County, served as president of the village council of Kimball at one time and was an active Guernsey cattle enthusiast. In 1928 he attended the International Dairy Congress in London on an appointment by President Coolidge. He traveled to Vienna in 1930 for post-graduate work, in 1949 toured South America and in 1955 spent the summer in Europe.

A member of the Minnesota State Medical Association, which honored him for fifty years of practice in 1944, Dr. Sherwood also belonged to the American Medical Association, the American Academy of General Practice, the Northern Minnesota Medical Association, which he served as president, the Stearns-Benton County Medical Society, which he also served as president, the Crow River Medical Society, of which he was a charter member, and the American Medical Association of Vienna. He was an active member of the medical staffs of the St. Cloud and Litchfield Hospitals and a member of the Minnesota Historical Society.

His other memberships included the Church of Christ in Kimball, the Masonic Lodge, the St. Cloud Kiwanis Club, and the State Bank of Kimball which he helped organize in 1901 and which he served as vice president and director.

Dr. Sherwood's wife, Mary, preceded him in death in 1955. He is survived by three daughters: Mrs. Edward Lax, Spokane, Washington; Mrs. Kenneth Lewis, Detroit, Michigan, and Mrs. Orville Nelson, St. Petersburg, Florida, and four grandchildren.

HOMER R. SMITH

Dr. Homer R. Smith, Minneapolis resident for over sixty-three years, died August 11, 1957. He was seventy-four years old.

Dr. Smith was born in Littleton, New Hampshire, and received his medical education at the University of Minnesota. He interned at Ancker Hospital, St. Paul, and later had his office in the Medical Arts Building in Minneapolis.

A member of the Hennepin County Medical Society, Dr. Smith was also a member of the '50 Club' of the Minnesota State Medical Association. His other memberships included the American Medical Association, Ark Lodge 176 of the Masons, the Scottish Rite Temple and the Optimist Club. He belonged to Grace Presbyterian Church, Minneapolis.

Survivors include his wife, Marian Latta; a daughter, Mrs. Fred C. Jones, South St. Paul, and a brother, Harlan, Minneapolis.

True progress in law, in medicine—in almost any area of vital human concern—will come from the discovery and cultivation of common interests by people who share a common purpose, unadulterated by special political objectives or ideological differences.—Editorial, *World Medical Journal*, May, 1956.

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

General Interest

Guest speaker at the July 14 dinner and rededication ceremonies of the expanded Iron Range Rehabilitation Center at Virginia, Minnesota, was **Dr. Frank H. Krusen**, head of the section on physical medicine at the Mayo Clinic and Mayo Foundation. Dr. Krusen is especially interested in community work in rehabilitation of the handicapped, and works with a number of groups throughout the state.

* * *

Dr. B. J. Cronwell, Austin, was recently elected to the board of directors of the Minnesota Heart Association.

* * *

The Group Health Federation of America at its annual meeting in July elected **Dr. William Kosiak**, medical director of the Community Health Center at Two Harbors, as secretary-treasurer of the federation.

* * *

The Minnesota State Board of Health has announced that **Dr. Sidney Finkelstein** will succeed **Dr. Mary C. Ghostley** as director of Health District 1 at Bemidji. Dr. Finkelstein, who has been serving as a sub-area director in the division of Indian Health of the U.S. Public Health Service at Bemidji, received his medical education at the Royal College of Surgeons, Edinburgh, Scotland, and has been taking advanced work in public health at the University of Minnesota.

"WHERE'S MINE? I'D LIKE TO DEFEND MYSELF."

Four Minnesota doctors included an African safari as part of their vacation schedule. **Dr. P. W. Harrison**, Worthington, and **Drs. Joseph Friberg**, Conrad Karleen, and **Joseph Resch**, Minneapolis, left in mid-July for a five-week trip to Nairobi, Kenya, British East Africa, for a combined hunting expedition and visit to medical missions in Africa. Dr. Friberg is a former medical missionary in Africa.

* * *

Dr. R. A. Belcher, specialist in internal medicine, commenced medical practice at the Little Falls Clinic in July. He was formerly associated with the clinic at Graceville, Minnesota.

* * *

At the annual meeting of the medical staff of the Pine County Memorial Hospital at Sandstone, July 16, the following officers were elected for the coming year: **Dr. H. W. Henry**, Hinckley, president; **Dr. E. G. Hubin**, Sandstone, vice president; **Dr. M. S. Munson**, Barnum and Willow River, secretary-treasurer. **Dr. G. Albin Mattson**, executive secretary of the Minneapolis War Memorial Blood Bank, was guest speaker at this meeting.

* * *

Construction of a modern medical center at Chaska, Minnesota, was begun in mid-July, according to **Dr. G. T. Schimelpfenig**, who has practiced in that community for the past twenty-five years.

* * *

Dr. Robert N. Barr, secretary and executive officer of the Minnesota State Board of Health, has been reappointed to a four-year term on the United States surgeon-general's advisory committee on Indian health.

* * *

St. Joseph, Minnesota, is the new location of **Dr. William Davidson**, a graduate of Duke University. In addition to medical practice in St. Joseph, Dr. Davidson will teach psychology at St. John's university and care for patients at the infirmaries at St. John's and the College of St. Benedict, located at St. Joseph.

* * *

Dr. George C. Kimmell has left his medical practice with the Interstate Clinic at Red Wing to become associated with **Dr. Henry P. Staub**, Minneapolis, in a pediatric practice.

* * *

Dr. Stanley B. Lindley, former superintendent of the Willmar State Hospital and presently director of professional services at the Veterans Administration Hospital at Knoxville, Iowa, has recently been appointed as manager of the Veterans Hospital at St. Cloud.

* * *

Dr. John A. Seaberg, manager of the Veterans Hospital, Minneapolis, since 1950, retired August 31. He has

Physicians & Hospitals
Supply Company
MINNEAPOLIS 3, MINNESOTA

MINNESOTA BLUE SHIELD-BLUE CROSS

Payments to physicians by Minnesota Blue Shield during the first half of 1957, exceeded by more than \$880,000 the amount paid for physicians' services to participant subscribers during the first half of 1956. From January 1, through June 30, 1957, Blue Shield paid \$4,218,673 for medical, surgical, obstetrical and related services rendered participant subscribers compared with \$3,337,492 paid for these services during the first six months of 1956. Blue Shield payments for physicians' services to participant subscribers during the first half of 1957 show average monthly payments of more than \$703,000. During no other six month period in Minnesota Blue Shield's history have total payments equaled the amount paid during the first half of 1957.

During the first six months of 1957, Blue Shield provided benefits for 149,359 doctors' services to subscribers. During the same period of 1956, Blue Shield paid physicians for 116,716 services rendered participant subscribers. The number of physicians' services for which Blue Shield benefits were provided during the first half of 1957 also exceeds the number of services provided Blue Shield benefits during any other similar period since Minnesota Blue Shield began operations in 1947.

If Blue Shield benefits for physicians' services to subscribers during the last half of 1957 equal or exceed the amount paid for them during the first half of 1957, Blue Shield payments to doctors during 1957 will exceed \$8,000,000 which is more than one million dollars

more than has been paid for physicians' services during any previous year.

Minnesota Blue Cross payments to hospitals totaled \$14,122,259.73 during the first six months of 1957, compared to \$11,630,990.84 for the same period in 1956. This amounted to an increase of approximately \$2,500,000.

The increase in hospital payments is attributable in varying degrees to four factors:

1. Increased enrollment. Blue Cross contracts increased from 397,518 as of June 30, 1956 to 424,873 in effect as of June 30, 1957 . . . an increase of approximately 6.9 per cent. Participant subscriber increased from 1,052,272 as of June 30, 1956 to 1,120,413 as of June 30, 1957.

2. Continued trend of popularity of Blue Cross higher benefit level contracts.

3. Increased usage. The 101,666 cases paid during the first six months of 1957 represent 488 cases paid per year per 1,000 contracts in effect, or an increase of 3.6 per cent over the incidence rate of 471 cases paid per 1,000 contracts protected during the same period in 1956. (Accident and maternity cases accounted for approximately one-half of the number of cases paid in this category, while over-all surgical care accounted for the remainder.)

4. Increased hospital costs. Ancillary costs for the first six months of 1957 (operating room, approved drugs, biologicals, etc.) were 5.9 per cent over costs for the same period in 1956.

PHYSICIANS URGED TO STUDY WORK POTENTIAL OF CONGESTIVE HEART PATIENTS

Employment horizons for cardiac patients with congestive failure are beginning to widen and their occupational potentialities merit further investigation, according to two specialists.

Dr. Leonard J. Goldwater, of the Columbia University School of Public Health and Administrative Medicine, and Dr. John M. Evans, of the George Washington University Hospital, state that refinements in diagnostic procedures and important improvements in drug therapy such as recently developed oral organomercurial diuretics have affected changing attitudes of the medical profession. They write in the journal *Industrial Medicine and Surgery* (26:182, 1957).

"The idea that persons having heart disease are able to work, and that they can be employed in a variety of jobs, is by no means new," they begin. Yet, "In spite of a rather voluminous literature, there rarely has been any mention of the employment of individuals having congestive heart failure." They do refer to several publications of recent years.

Physicians have been less restrictive in their advice, and the general public has become less apprehensive about the dangers of heart disease, it is stated. "The major efforts in public education, particularly those connected with fund raising, have shifted their emphasis from the 'scare' technique to that of pointing out the positive and hopeful aspects."

Thus far, somewhat limited study indicates that no diverse effects occur when persons with heart disease are intelligently placed at work and remain under competent medical supervision, the authors add.

"The physician now has at his command an array of therapeutic agents which singly or in combination assist the ailing heart to carry on. Where congestive failure has occurred, it is usually necessary to employ a digitalis preparation and one or more diuretic agents.

"Recently developed oral mercurial diuretics appear to be an important addition to the physician's therapeutic armamentarium since, among other things, they reduce the necessity for frequent diuretic therapy."

The authors include a few illustrative case histories of people who have carried on active occupational lives despite congestive failure. One is a mechanic at an airport, "frequently working overtime with no difficulty." Another is a social worker with considerable travel. Therapy in these and other cases is said to include the oral organomercurial Neohydrin, low salt diet and digitalis.

RECOMMENDED: A GOOD CRY

Men might live longer if, like women, they could have a good cry now and then, or some male equivalent, suggests Dr. James O. Bond of the Florida State Board of Health. Perhaps men "need to learn more from women either how to avoid emotional tension or deal with it in less damaging ways than development of coronary artery disease," he said. Greater stress, or less relief from it, is only one possible explanation why men do not live as long as women. Women are more ready to acknowledge illness early and seek treatment for it, he added.—American Chemical Society, Miami.

Replies to advertisements with key numbers should be mailed in care of MINNESOTA MEDICINE, 2642 University Avenue, Saint Paul 14, Minnesota.

WANTED—Board or board-eligible OTOLARYNGOLOGIST, qualified in endoscopy, to join clinic of five men, with expectation of becoming full partner in group. Practice limited to Eye, Ear, Nose, Throat. Write: Morsman Clinic, Hibbing, Minnesota.

OTOLARYNGOLOGIST WANTED—BOARD OR BOARD ELIGIBLE to join Clinic group of nineteen. Attractive salary leading to partnership. Unlimited potential. Completely modern EENT Department. Lake Michigan city of 45,000. Write Box 487, Sheboygan, Wisconsin.

WANTED—General practitioner or surgeon to take over practice of doctors removing, for reasons of health, from west central Minnesota town of 2,600, with new modern hospital, and with available clinic building and equipment, and surrounding 20-mile radius area. Address E-572, care MINNESOTA MEDICINE.

WANTED—General practitioner to join busy general practitioner in Northeastern Minnesota. Terms open. Excellent office and hospital facilities available. Address E-589, care MINNESOTA MEDICINE.

GENERAL PRACTITIONERS—Two capable generalists needed for complete practice—expanding group serving three communities. New clinic facilities, new accredited hospitals. Specialist consultant available in group and expert radiologists and pathologists. Full hospital privileges immediately. Progressive area, finest schools and churches. Good recreational area, hunting and fishing. Salary open. Partnership possible within three years. Contact Mr. James Streitz, Manager, Mesaba Clinic, Hibbing, Minnesota.

ASSISTANT WANTED—Very active general practice in Central Minnesota. New, excellent hospital in town. New clinic building. Good hunting and fishing. Address E-594, care MINNESOTA MEDICINE.

WANTED—General Practitioner in Minnesota town of 750 in fine farming territory. Excellent office facilities. Now no other doctor in town. Address Belgrade Commercial Club, George Borgerding, President, Belgrade, Minnesota.

WANTED—Minnesota-licensed practitioner; unopposed; prosperous rural village, central Minnesota; completely equipped clinic; residence combination; open hospitals nearby; for sale or low rental with option to purchase; will introduce; leaving, postgraduate study; give personal data. Address E-600, care MINNESOTA MEDICINE.

PHYSICIANS WANTED—If you are looking for opportunity, the 1200-bed state mental hospital, miles from the Twin Cities at Anoka, Minnesota, accepting applications for staff physicians and psychiatrists. A new salary plan, liberal vacation and sick leave benefits, a pleasant and "heads-up" staff and superintendent, plus plans for a new 500-bed addition up to a *real opportunity*. If money as such does not mean EVERYTHING to you, give us a call. Direct replies to: Dr. Donald B. Peterson, Superintendent, Anoka State Hospital, Box 511, Anoka, Minnesota.

EXCELLENT OPPORTUNITY—For recent graduate in five-man Clinic in active community adjacent to Twin Cities. All modern clinical facilities and new up-to-date hospital available. Good opportunity for permanent attachment to suitable man. Must qualify for license in Minnesota and Wisconsin. Detailed information available. Address E-603, care MINNESOTA MEDICINE.

GENERAL PRACTITIONER—Opportunity to establish excellent practice in attractive Southern Minnesota area needing M.D. Progressive community assured bright future for right man. Can gross \$20,000 first year. Contact Saint Clair Medical & Dental Building Corporation, Saint Clair, Minnesota.

WANTED—Junior Staff Physician interested in internal medicine and chest diseases for work in a well-equipped and well-staffed county tuberculosis sanatorium near Duluth. Salary and housing plus full maintenance. Immediate opening. Write R. W. Backlund, M.D., Nopeming Sanatorium, Nopeming, Minnesota.

WANTED—General Practitioner for Lamberton, population 1,200, Redwood County, southwestern Minnesota. Practice unopposed; nothing to buy; free use of community-owned general and diagnostic equipment; eight-room, first-floor office; also patients charts and records of large active practice for nine years. Nearest hospital (new) 15 miles; nearest M.D. 10 miles. Leaving to specialize; will continue practice until replaced. Large modern rambler home available. Contact Dr. Morton Roan or T. E. Kuehl, Lamberton, Minnesota.

WANTED—General Practitioner to take over suburban office in Twin Cities, either as independent or associate. Excellent practice established. Nothing to buy. Write E-601, care MINNESOTA MEDICINE.

ASSISTANT WANTED—Very active general practice in Southern Minnesota. Partnership after one year. Address E-602, care MINNESOTA MEDICINE.

WANTED—General Practitioner. Salary \$15,000 annually. Prefer married physician who has complete military obligations. No investment required. Partnership after three years. No office overhead. Salary is net. Must have car and pay for its upkeep, as well as own living expenses. Must have Minnesota license. Address E-598, care MINNESOTA MEDICINE.

FOR SALE—100 M.A. Keleket X-ray. Used very little. In the best of condition. Address E-604, care MINNESOTA MEDICINE.

Rational Therapy with Tranquilizing Drugs

A Psychiatrist's Views

ROBERT L. FAUCETT, M.D.
Rochester, Minnesota

THE age of tranquility is indeed upon us. The advent of a whole new class of drugs in the past five years has created a great surge of interest in the chemical control of the symptoms of mental illness, and of the disrupting effects of anxiety and tension. Mankind long has sought such an elixir and has tried alcohol, hashish, the poppy seed and, more recently, bromides and barbiturates as the answer to these disagreeable sensations. None of these agents have sufficed. They may change man's awareness of the harsh and unpalatable realities of his past and present, but they have been of no help alone in dealing with these facts realistically and indeed often have compounded the problem. The tranquilizers represent a new addition to the physician's therapeutic assets but, as with any other therapy, they must be used with rationality and perspicacity.

The drugs were first tried on patients in state hospitals and the dramatic effects on violent, assaultive, out-of-contact, overactive, psychotic patients have led to such florid predictions in the public press as follows from the *New York Times Magazine*:

"The dramatic, even miraculous, results of treating insanity with the so-called 'tranquilizing' drugs in recent years have confirmed the poet's intuitive understanding of the dark curtain which so often shuts human minds away from reality. This is the story of a promise of a new age when most cases of insanity can be controlled by combinations of drugs, as diabetes, for example, is now controlled by insulin."

Such outbursts of unfounded optimism, supported by uncritical clinical trials and sustained by tons of commercial advertising, the extravagant claims

Dr. Faucett is in the Section of Psychiatry, Mayo Clinic and Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

of a few vocal proponents and pharmaceutical advocates, and the wistful hopes of the practitioner for something to help the clamoring neurotics whose symptoms he does not understand and often does not wish to hear, have catapulted these drugs into fourth place in dollar volume in medical practice today, even threatening the old favorite, the laxatives, with an estimated expenditure in 1957 of \$125,000,000. Even with the plethora of preparations presently available, there are estimated to be about forty such drugs now in clinical trial that have not been released to an uncritical public.

While these drugs do have remarkable effects in certain circumstances, the above facts require a sober second look and a consideration of the possibility that such agents frequently are prescribed to preserve the tranquility of the physician instead of the patient. The continued uncritical use of a class of drugs frequently brings about a reaction of overgeneralized pessimism that obscures their real value.

Current Concepts of Mental Disease as Related to Tranquilizers

Man is a symbolizing, remembering animal, biologically and socially dependent on the protectiveness of his environment for a long time after birth. During this period, he develops personality techniques and operations to deal with the forces in this environment that threaten his well-being. These techniques, by operation of the general principle of economy of energy, tend to become automatic or unconscious but always are directed toward minimizing the intolerable effects of anxiety. Because these personality techniques or defense systems become automatic, a misperception of current reality distorted by past experience often occurs; when the system is inadequate to allow a person to face present problems, regression to more

primitive and infantile modes of behavior may occur. These maneuvers, because they occur automatically and unconsciously, are frequently not a good adjustive technique and anxiety or aberrant behavior occurs, usually in proportion to the emotional trauma or deprivations of early life.

The stress that brings about abnormal anxiety or aberrant behavior or somatic manifestations may be quantitative, as was seen in combat neuroses in which it was learned that every man has his breaking point, or it may be qualitative, in that the stress objectively does not look overwhelming but, because it is specifically reminiscent of past traumatic events, causes overdetermined reactions. Such stresses bring about the decompensation of previously adequate defense systems and the appearance of anxiety or other manifestations. On the other hand, the defenses against anxiety may be of borderline effectiveness throughout life, and consequent constriction of the personality may be seen. This constriction of personality minimizes the flexibility and resiliency of the person to meet the ordinary stresses of living and so he lives in a constant state of fearful apprehension. Any treatment that presumes to deal with anxiety or neurotic or psychotic manifestations without taking these facts into account is irrational, whether successful or not.

This concept of mental illness also makes it apparent that drugs alone will not likely "cure" or even manage the symptoms of mental illness. It does point a way, however, in which drugs can be an invaluable part of an over-all plan of management.

Zeller and associates¹ have commented as follows:

"Because of the rather specific action that these drugs have upon certain areas of the brain, they seem to produce an effect similar to that seen in patients with lobotomy. Some have described this effect as a peculiar insulation of the patient against incoming stressful stimuli from the environment. From the psychodynamic standpoint, such an insulating effect is important. Stressful stimuli arising from within or from without the individual usually evoke anxiety, and each individual handles his anxieties according to previously learned ideational and behavioral responses. If the emotionally upset patient can be guarded against incoming stressful stimuli that potentially can further upset the homeostasis of his internal environment, he will be better able to mobilize his previously learned defenses and coping mechanisms in order to handle more efficiently the anxiety or affect evoked by the forces that threaten him from within and from without."

Usefulness of Tranquilizers

The cogent description just quoted points the way toward the usefulness of these drugs but indicates that they only provide time for the patient to mobilize his assets, time for the stressful situation to subside or time for the physician to provide psychotherapeutic help, whether it be supportive, re-educative, manipulative, uncovering or reconstructive, as in psychoanalysis.

Drugs alone are not the answer to the management of anxiety or emotional illness, but management should be directed simultaneously toward several aspects of the total situation. A major factor in this is the performance of the physician. The physician who fails to undertake to understand the totality of the situation cannot distinguish between the assets and liabilities inherent in it; he will find it necessary to administer drugs and, because he offers nothing else, he tends to make the use of drugs essential to his patient. On the other hand, the wise physician will administer drugs as a specific part of the physician-patient relationship and not as a substitute for it. The need for this interpersonal contact is even becoming apparent as these drugs make their effect felt in state-hospital populations; as they make patients accessible to interpersonal relations, the patients are able to participate in their treatment. This challenges the hospital personnel to provide opportunities to exploit this participation in order to hasten and solidify improvement. Many physicians consider that this is the most important therapeutic effect of the drugs.

Rational use of drugs thus requires a rational plan of management. This means that data must be accumulated and a history taken. The physician must determine whether events leading to the incapacity are quantitative or qualitative, and he must judge how long the noxious events will be operative and whether they can be manipulated. He cannot expect drugs to make the patient better adjusted than he was before the symptoms commenced. He must determine whether the situation is one that will be temporary by its nature and must judge the acuteness of its onset.

Three groups of situations typify those in which drugs will be a most valuable adjunct. The first group includes acute situations in which the sudden interposition of stress is clearly apparent and temporary in nature, especially as a result of illness or medical or surgical intervention. This is seen most sharply in postoperative psychosis or in

disrupting metabolic disease. In these situations, tranquilizers are at their brilliant best, although even here they do not replace intelligent and humane nursing care. These drugs are also valuable adjuncts when narcotics must be resorted to for the management of pain; their use will avoid to some extent the dangers of development of tolerance or addiction.

The second group includes situations in which clearly apparent changes are present in the interpersonal situation that have acutely precipitated the patient's anxiety but that are temporary in nature, such as financial catastrophes, family disruption or accidents, or in which events that specifically challenge previously adequate defense systems have occurred and in which time (not more than four to six weeks) may be necessary for integration and readjustment to occur.

Finally, there are situations in which the anxiety has reached such high levels as to disrupt or threaten to paralyze the patient's adaptive responses. This is frequently the situation in ambulatory psychotic patients who have threatening panic reactions or all-pervading pananxiety.

It has been my experience and that of my associates that these drugs are usually of minimal value when symptoms other than tension and anxiety have appeared, such as conversion hysteria, somatic delusions or other somatized anxiety, or when the anxiety has continued long enough to lead to organized neurotic symptoms such as phobias, obsessions and paranoid ideas. They are useless in depressions, often actually making the patient worse. There are certain kinds of tense, dependent, rôle-playing persons whose adjustive technique is solely in placating their environment. To do this, they depend on cues received from those around them. Since tranquilizers blur organized perceptual cues somewhat, these drugs may actually make such patients worse and precipitate more insomnia and anxiety or even depressive reactions. Many hypochondriacal patients

will incorporate the side effects of the drugs into their symptomatology, thus making the situation even more complicated.

Mention should be made of the side reactions of drowsiness, with its consequent dangerous effects on the ability to drive automobiles, cutaneous rashes, jaundice, parkinsonism and the precipitation of depression. As already indicated, the factor of cost also must be considered.

Conclusions

A number of principles must be kept in mind when the so-called tranquilizers are being prescribed. These factors include the following admonitions:

1. Collect the data that offer leads to the cause of the anxiety.
2. Devise a rational plan of management that attacks several aspects of the situation simultaneously.
3. Do not prescribe tranquilizers for your own peace of mind.
4. Consider doing nothing.
5. Ask psychiatric consultation.
6. Remember that these drugs are costly and not entirely harmless, and that living continuously in a chemical strait jacket does not constitute a desirable way of life.
7. Keep in mind that administration of drugs cannot remedy the defects of human personality that plague people most, such as dependency, irresponsibility, meanness and lack of respect for the rights of others.

When asked his opinion of the "don't give a damn" drugs, Dr. Karl Menninger said, "Society would be better off if someone invented a 'do give a damn' drug."

TRANQUILIZERS VS. ARCHITECTURE

Tranquilizers have "struck a provocative blow at institutional architecture," reports *Architectural Forum* magazine. The California legislature, the magazine said, has recommended that "major expenditures on mental hospitals be postponed" until the full effect of the new drugs on design is evaluated. California lawmakers have

been advised by a special committee that tranquilizing drugs have started a new trend "away from the maximum security type of facility and toward the 'normal' hospital facility."—*South Dakota Journal of Medicine*, August, 1957.

Use of Induced Cardiac Arrest in Open Heart Surgery

Results in Seventy Patients

PETER ALLEN, M.D.
C. WALTON LILLEHEI, M.D.
Minneapolis, Minnesota

WITH the advent of extracorporeal circulation, a new era in cardiac surgery began, and for the first time it became possible to open the diseased heart without fear of ventricular fibrillation and without being harassed by limitation of operating time. However, while extracorporeal circulation solved these obstacles and has made curative surgery possible for the first time for ventricular septal defects, atrioventricularis communis tetralogy of Fallot and a variety of other cardiac malformations,^{1,2} at the same time other problems became evident.

When the interior of the by-passed heart is exposed by cardiotomy, the continued activity of the myocardium sometimes makes accurate repair of the defect difficult. Furthermore, the operative field may be obscured by blood from the coronary sinus passing into the right ventricle, by bronchial collateral circulation either passing retrograde from the pulmonary artery or flowing into the left heart via the pulmonary veins and across a ventricular or auricular septal defect. Lastly, blood may obscure the field by spilling across the aortic valve which, even though normal, often exhibits varying degrees of incompetency during total body perfusion.

To reduce in quantity blood obscuring the intracardiac field during surgery, a Rumel tourniquet often has been used to constrict the ascending aorta just distal to the coronary ostia.² Thus, by intermittent aortic occlusion, inflow of blood from the coronary sinus and reflux through the aortic valve was prevented. This method has proved valuable and is still utilized frequently for the simpler intracardiac procedures, but the persistent myocardial activity may make accurate surgical repair of some less accessible septal defects difficult and occasionally incomplete.

In 1955, Melrose³ described chemically induced cardiac arrest as an adjunct to open heart surgery. The heart could be stilled, its metabolism lowered, the surgical field dried and danger of air embolism greatly reduced. Several arresting drugs have been used experimentally but only two, to date, acetylcholine and potassium citrate, have seemed to fulfill the properties of an effective cardioplegic agent for human use; namely, the rapid induction of complete cardiac standstill, rapid restoration of sinus rhythm with reperfusion of the coronary arteries and, thirdly the absence of systemic toxicity to the drug. Lam,⁴ has favored the use of acetylcholine, and Effler and associates⁵ potassium citrate to induce cardiac arrest. At the University of Minnesota Hospitals both potassium citrate and acetylcholine have been employed.

Sidney Ringer,¹⁰ in 1883, first recorded depression of the myocardium when potassium chloride was added to the perfusing fluid of an isolated heart, but at the same time he was unaware of the mechanism involved.

If one takes a single resting cell as the example, the outside of the cell membrane contains positive charges and the inside, negative charges which result in the cell having a negative electrical potential of about 90 millivolts. When the cell is stimulated to contraction, sodium passes into the cell and potassium is passed outward into the extracellular compartment. If the extracellular potassium concentration is increased by the injection of potassium citrate, then potassium within the cell is no longer able to pass outward against the high concentration. The citrate ion by combining with calcium further augments this effect because of the reciprocal relationship between calcium and potassium ions. The result is increased positive charges within the cell from the retained intracellular potassium, the negative electrical potential of the cell is thus

Dr. Allen is a McLaughlin Fellow in Cardiac Surgery (Canada).

rapidly reduced toward zero potential and is unable to respond to further stimulation until the extracellular potassium concentration is reduced. It is then possible for positively charged potassium ions to pass out of the cell and restore the negative intracellular potential. However, while the cell is thus functionally inactive, its metabolism continues and, indeed, Rohde⁶ has shown that the oxygen consumption of the potassium arrested heart is reduced by only 50 per cent over the beating, non-working heart.

Cardiac arrest induced by acetylcholine, in contrast to potassium asystole, does not act by reducing the negative electrical potential of the myocardial cells but blocks neural impulses at the myoneural junction and prevents cardiac contraction. Normally, the response to stimulation of cells of the myocardium is due to the release of acetylcholine at the myoneural end plate. This chemical substance bridges a synapse between nerve and muscle fiber and allows the neural impulse to produce a muscular contraction. Subsequently, cholinesterase rapidly hydrolyses acetylcholine to choline and acetic acid; as a result, the synaptic membrane is repolarized and able to respond to successive neural impulses. When the coronary arteries are perfused with acetylcholine, the myoneural end plate becomes rapidly depolarized and, as there is insufficient cholinesterase to hydralize or break down the greatly increased concentration of acetylcholine, the end plate cannot transmit further impulses. Consequently, succeeding nerve impulses to the myocardium produce no response until the heart is reperfused with oxygenated blood, excessive acetylcholine is washed out, and the myoneural junction is once again repolarized.⁷

Cardioplegic drugs are administered by rapid injection into the ascending aorta just proximal to a clamp placed distal to the ostia of the coronary arteries (Fig. 1). Action of the myocardium ceases quickly; it remains dormant until the aortic clamp is removed and oxygenated blood, perfusing the coronary arteries, washes out the paralyzing drug.

Acetylcholine, diluted in normal saline and injected at a concentration of 10 mgm. per kilogram of body weight, produces cardiac arrest, but a single contraction will occur each time the myocardium is touched. In using potassium asystole, it was found that the higher the concentration of potassium used or the greater the

duration of arrest, the longer it took to resuscitate the heart once coronary perfusion was restarted. At present, a 2.5 per cent solution (25 mgm./cc.) is used and is prepared by expanding a 25 per

Fig. 1. Method for inducing complete cardiac arrest to facilitate reparative surgical procedures during total cardiopulmonary bypass utilizing the pump-oxygenator.

cent solution of potassium citrate with the patient's own blood.³ The upper limit of safety has not been established, but a solution of less than 1 milligram per cc. (0.1 per cent solution) will not produce cardiac arrest.

Results

The average amount of 2.5 per cent potassium citrate solution needed to produce asystole in our cases was 33 cc., most of the pediatric patients requiring only 10 to 25 cc. The greatest volume used was 100 cc. in an adult with aortic insufficiency. The average duration of cardiac arrest utilizing potassium has been eighteen minutes, the longest being thirty-five minutes (successful)* With acetylcholine, the average duration of asystole has been seven minutes and the longest was thirteen minutes. Contrary to the policy of some, we have not induced cardiac arrest routinely in cases undergoing intracardiac surgery, but rather have reserved its use for patients where myo-

*An additional patient, not included in this series because no cardioplegic agent was utilized, had an uncomplicated recovery from an anoxic arrest period of thirty-three minutes during which a ventricular septal defect was closed and the transected aorta was reanastomosed just above the coronaries. Upon resumption of the coronary flow in this patient the deeply cyanotic myocardium fibrillated, but resumed a spontaneous sinus-rhythm before an electrical shock could be given.

cardial activity or excessive blood in the field obscured vision and increased the possibility of an incomplete repair. This decision is made after the heart has been opened and the pathol-

patients are progressing well several months after surgery in spite of persisting complete A-V dissociation. Five patients have died, all from the adverse effects of heart block.

TABLE I. POTASSIUM CITRATE INDUCED ASYSTOLE AS AN ADJUNCT TO OPEN CARDIOTOMY WITH THE PUMP OXYGENATOR

Lesion	No. Patients	Deaths (All Causes)	Complete Heart Block				Unable to Restart Heart
			No.	Died of Block	Reverted to Sinus Rhythm	Permanent	
Ventricular septal defect	31	7	7	3*	2	2	0
Tetralogy of fallot	23	6	7	2	5	0	0
Ruptured aneurysm of sinus of valsalva	2	0	0				
Aortic regurgitation†	2	2					2
Single ventricle	1	0	1		1		
Totals	59	15	15	5	8	2	2

*One of these deaths was late (three months postoperatively) in a patient whose defect was completely closed.
†One patient had a small ventricular defect also.

TABLE II. ACETYLCHOLINE ASYSTOLE AS AN ADJUNCT TO OPEN CARDIOTOMY WITH THE PUMP OXYGENATOR

	No. Patients	Deaths	Complete Heart Block
Ventricular septal defects	5	0	0
Aortic stenosis	6	1*	0
Total	11	1	0

*Calcific aortic stenosis

ogy assessed, thus further reducing the duration of asystole needed. At the University Hospitals in Minneapolis, induced asystole has been used in this manner in seventy patients to facilitate difficult exposures and to expedite the repair of isolated ventricular septal defects or those seen in tetralogy of Fallot. These seventy cases include patients with a variety of congenital and acquired cardiac lesions (Tables I, II).

In this center, the increased incidence of persisting complete atrioventricular dissociation following completion of potassium arrest has been a deterrent to its use in every case of intracardiac surgery where asystole might be convenient. Moreover, in two patients both with aortic valvular disease it was impossible to restart their hearts after only brief intervals of potassium arrest of four and eleven minutes, respectively.

In our series (Table I), there were fifteen cases (25 per cent) of persisting complete heart block (complete atrioventricular dissociation) following potassium arrest in surgery. Eight have reverted to sinus rhythm usually within seven days. Two

In the first 165 patients undergoing operative repair of a ventricular septal defect (includes tetralogy of Fallot and atrioventricularis communis patients) before induced cardiac arrest techniques were available, nineteen (11.5 per cent) developed complete heart block which persisted following surgery. Fourteen died as a direct result of heart block, four reverted to sinus rhythm, and one is alive eighteen months later with complete heart block and an apex rate of forty-five to fifty beats per minute.

Discussion

To date, at the University of Minnesota Heart Hospitals, 360 patients have had total cardiopulmonary bypass for intracardiac surgery utilizing extracorporeal circulation. Two hundred and twenty-five of these patients were operated upon before induced cardiac asystole was available, and the remaining 135 since. Upon the basis of this experience it is clear to us that the use of cardioplegic agents has been a great help in allowing improved exposure of less accessible ventricular septal defects and facilitating a complete, durable repair. However, the increased incidence of immediate complete heart block in these patients cannot be disregarded. When septal defects are repaired in an actively beating heart, occasionally (six cases in 165) the offending suture responsible for heart block is observed and its removal may restore normal rhythm. However, when the heart is arrested, it is impossible to observe the offending suture, and complete A-V

dissociation may be observed only after the heart beat is restored.

To some extent this undesirable sequel of arrest techniques has been offset by vastly improved treatment of surgical heart block. The drug Isuprel[†], which increases ventricular rate by direct action on the myocardium⁸, has decreased the mortality of this complication from almost 100 per cent to about 50 per cent.

More recently, when operative heart block persists, a fine silver-plated copper wire sutured into the myocardium of the right ventricle, brought out on the chest through a minute stab wound and connected to an electrical cardiac pacemaker, has been used to maintain a ventricular rate of 100-120/minute during the critical postoperative period the voltages required are low (2 to 5 volts), the control of the heart rate is complete, and the patient is unaware of any unpleasant shocks as occur with the external pacemaker. We have usually continued to use Isuprel in conjunction with the electrical pacemaker in cases of persisting heart block following surgery, so that in the early postoperative period, if the pacemaker for some reason should fail, Isuprel may maintain a satisfactory apex beat. Conversely, as the Isuprel gradually becomes less effective, the electrical pacemaker continues to maintain a satisfactory ventricular contraction. As a rule, if sinus rhythm has not occurred within a week to ten days, spontaneous idioventricular contractions begin to interfere with the action of the electrical pacemaker, ventricular action becomes irregular, and the electrical stimulator is best terminated. In such cases, Isuprel usually continues to have some effect on the heart beat, but gradually the apex rate slows to 50 to 70 beats per minute, the reduced rate being compensated by an increased stroke volume. By this form of therapy the acute mortality of complete block has fallen to virtually zero.

Although it has been difficult to quantitate because of the multitude of factors involved, the "arrested" patients appear to have had a greater incidence of tachycardia in the immediate postoperative interval. For most, but not all, of the patients this arrhythmia appears to have been a non-fatal complication.

The reader may be tempted to compare the results (Tables I, II) of the use of potassium citrate and acetylcholine. However, these two series are

not comparable at all neither from the standpoint of the number of cases involved nor from the types of cases in which these agents have been used. For, it is our conclusion based upon this experience, that these two cardioplegics are not competitors. Each, it appears, has a role of value with perhaps some, but relatively little overlapping.

Potassium citrate injection produces immediately a completely flaccid heart totally unresponsive to any mechanical stimulus and thus has been of most value in difficult anatomical problems where complete relaxation is desirable often for a relatively long period. The successful single ventricle repair in this series would not have been possible without arrest and would, in our opinion, have been very difficult in the more responsive acetylcholine arrested heart. Moreover, hearts arrested with potassium show a slower return to their contracting state. Possibly this is a result of the profound nature of the arrest and the time necessary for the potassium to move out of the cells. However, the persistence for some hours of a hyperpotassemia pattern in the electrocardiograms of some of these patients suggests that the effects are not immediately and completely reversible.

Thus, in the present state of our knowledge, we believe it better to avoid using potassium arrest, if possible, in patients with extensive myocardial damage from any cause, those with a relative coronary insufficiency such as exists in far advanced lesions of the aortic valve with extensive left ventricle hypertrophy, or in patients with appreciable coronary arteriosclerosis present. Intracardiac procedures requiring cross clamping of the aorta in such patients may be better managed by retrograde perfusion of the coronary sinus with or without a cardioplegic agent added⁹.

Acetylcholine, on the other hand, produces a less profound degree of arrest. The heart after receiving the agent into the coronary circulation often continues to beat for a minute or two at a slower rate before complete asystole occurs. This fact has suggested that in part the arrest may be anoxic, but this is conjectural at present. These acetylcholine arrested hearts, so to speak, are "straining at the bit." They will respond to each mechanical stimulus of the myocardium by a contraction. Moreover, acetylcholine is unstable and its effects are more quickly reversed by the restoration of coronary perfusion. In addition, atropine, a potent antidote, is available if needed. These characteristics of acetylcholine arrest have

[†]Available from Winthrop-Stearns Company.

made it particularly valuable in patients with advanced aortic valvular disease where the left ventricular hypertrophy has exceeded the available coronary artery blood supply and a significant degree of coronary insufficiency exists.

Moreover, acetylcholine has been of value also in relatively simple ventricular defects where a few minutes of asystole was deemed very helpful and convenient, but in which the profound degree of arrest characteristic of potassium was not necessary.

In conclusion, the use of cardioplegics to stop temporarily the beat of the heart with concomitant clamping of the coronary arterial flow allows full realization of one of the major goals of open heart surgery; namely, an operative field which is both dry and motionless. Although these agents have a measurable morbidity and mortality related to their use, recognition of these limitations together with their use in selected patients where vital to complete repair has contributed along with a number of other factors to a further significant lowering of the risk of open heart surgery. Thus, in the last forty consecutive open heart operations carried out by the authors utilizing total cardiopulmonary bypass with the pump-oxygenator and for a variety of cardiac lesions such as listed in Tables I and II, there has been only one death (2.5 per cent). Seventeen of these forty patients had potassium arrest with six complete heart blocks occurring (all reverting later). The one death occurred in this potassium arrested group, but was not related to the arrest in this patient. Eight of these forty patients were arrested with acetylcholine with no blocks or deaths. The re-

maining fifteen patients had no arrest measures used during reparative surgery with two complete blocks occurring (reverting later) and no deaths.

HELP IN TREATING PLANTAR WARTS GAINED FROM X-RAYS

The incidence of plantar warts has increased in recent years, possibly due to more participation in sports by recreation-minded Americans, and treatment by x-rays of these growths has produced gratifying results.

This is the report of a physician associated with the Duke University Medical School in Durham, North Carolina. He is Dr. Robert J. Reeves, and his report on plantar warts, which apparently are caused by a virus infection and occur most often on the ball of the foot, appeared in the November, 1956, issue of *The American Journal of Roentgenology, Radium Therapy and Nuclear Medicine*.

"The incidence of plantar warts has appeared to increase in recent years, possibly due to increasing popularity of sports and the frequent use of public shower baths and locker rooms—and this may also account for

the increasing frequency in persons of high school and college age," Dr. Reeves pointed out.

Other conclusions by the North Carolina radiologist:

Gratifying results from the use of x-rays have led to general acceptance of this method, which is painless in application and usually produces little discomfort.

In one series of 208 patients reported, there were excellent results in 98 per cent.

If the radiation treatment should fail, Dr. Reeves advised against retreating the area with irradiation.

The symptoms of plantar warts vary from the sensation of a pebble in the shoe to marked disability, and treatment has often been delayed because of failure to recognize the condition or because of the indiscriminate use of such corrective measures as acids, frequent parings and callus file.

Pitfalls in Electrocardiographic Interpretation

RAYMOND D. PRUITT, M.D.
Rochester, Minnesota

DEFINING the pitfalls of electrocardiography constitutes an undertaking readily extended into every phase of electrocardiographic interpretation. If one is to avoid exhaustion, this discussion must be of a disciplined and selective sort that leads but a short way into what is hoped may prove to be a few of many rewarding byways. In order to lend some form and continuity to matters naturally incohesive, I have arranged this presentation under six headings.

The Human Comedy

*"When we are born, we cry that we are come
To this great stage of fools."†*

Technical errors can be a source of confusion in electrocardiographic interpretation. The modern electrocardiograph is remarkably foolproof, but necessity still demands the attachment of a specific lead wire to a designated extremity. In Figure 1 are reproduced a series of electrocardiograms from a forty-eight-year-old man. The record of April 30, 1950, was made at the time he consulted his physician because of symptoms related to nervous tension. A week later, the patient experienced an episode of pain in his thorax lasting half an hour. Although this pain was not of a character affording convincing evidence of coronary insufficiency, the possibility of posterior myocardial infarction was entertained seriously if only transiently after review of the electrocardiogram dated May 7. In the record dated May 18, all complexes were within the limits of normal. The peculiarities in form of the deflections on May 7 are such that, as compared with the record of May 18, lead I = — lead III, lead II = — lead II and lead III = — lead I. This relationship would result if, in recording the tracing of May 7, the proper attachments of the electrodes to the right arm and the left leg were

reversed. No other single interchange of extremity electrodes matches this one as a means of producing a topsy-turvy electrocardiogram.

Calling such errors "technical" is not intended to convey that all such mistakes are made by lab-

Fig. 1. In the electrocardiogram dated 5-7-50, the proper attachments of the electrodes to the right arm and the left leg were reversed. The resulting deformities in the ventricular complexes simulate those of posterior myocardial infarction. The other two tracings in this figure were made with the electrodes properly attached.

oratory technicians. The incidence of such errors is negligible among experienced technicians; however, when the physician turns in to lend a helping hand, the results may become novel and unpredictable.

Origins Are Important

*Establish first the source and
nature of ventricular excitation.*

Electrocardiographic identification of ventricular hypertrophy and localized myocardial injury

From the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is part of the Graduate School of the University of Minnesota.

†King Lear: Act IV, Scene VI.

rests on analysis and interpretation of the form of the ventricular complexes. Essential to such analysis and interpretation are movement of the excitation process into the ventricles from a source

the duration of that complex. This peculiarity is believed to result from anomalous excitation of the ventricular myocardium as a consequence either of unusually rapid spread of excitation

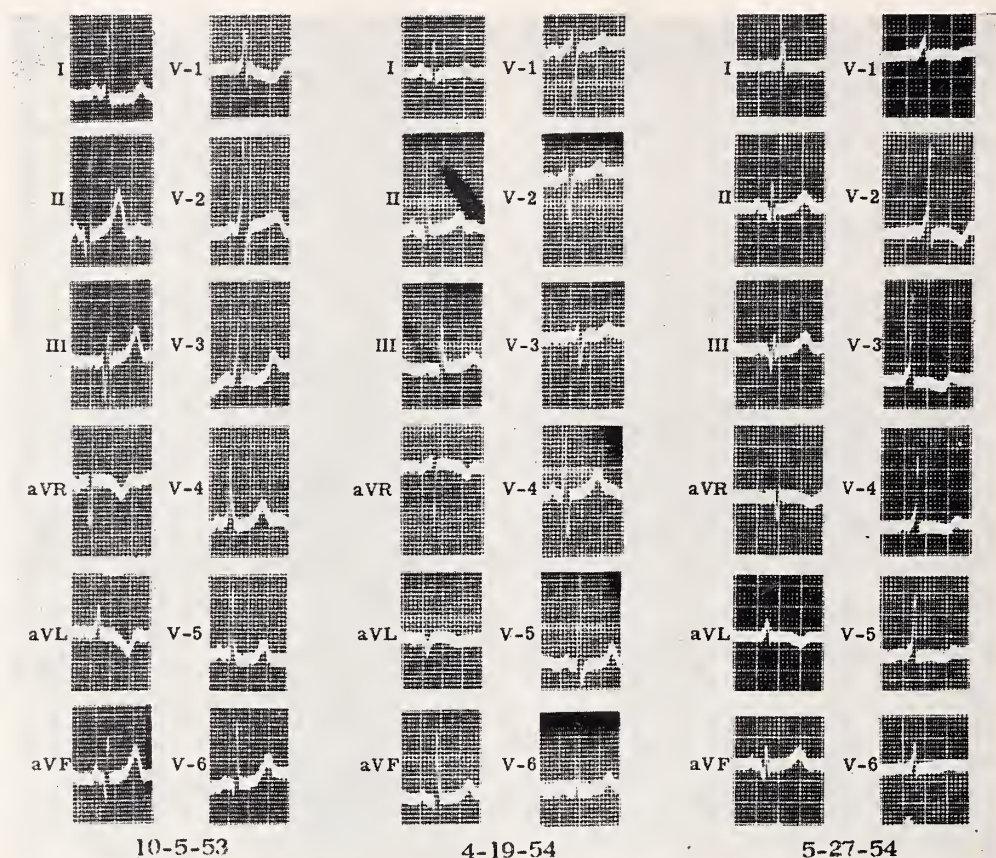

Fig. 2. Electrocardiograms recorded from a patient having the Wolff-Parkinson-White syndrome. When anomalous atrioventricular conduction occurred, as in the records of 10-5-53 and 5-27-54, QRS deformities suggestive of posterolateral infarction were present. These changes disappeared when normal atrioventricular conduction was present (4-19-54).

above the bifurcation of the atrioventricular bundle and spread of excitation through the ventricles over normally functioning bundle branches and subendocardial pathways. For example, distortion of the ventricular complexes attending idioventricular rhythms or left bundle-branch block may obscure the alterations produced by hypertrophy or destruction of myocardial fibers.

In illustration of this category of pitfalls, a series of electrocardiograms have been selected that were recorded from a twenty-eight-year-old woman who had the Wolff-Parkinson-White syndrome (Fig. 2). She was subject to paroxysms of tachycardia. Her electrocardiogram dated October 5, 1953, disclosed an unusually short P-R interval, the final portion of the P wave merging with the initial component of the QRS complex to prolong

through the usual atrioventricular pathway or rapid spread over an aberrant pathway (bundle of Kent). In this patient, anomalous excitation of the ventricles resulted in the presence of Q deflections in leads II, III and aVF, suggestive of posterior myocardial infarction. These changes, combined with a sense of precordial oppression noted by the patient during episodes of tachycardia, led to consideration of a diagnosis of posterior myocardial infarction by the attending physician. Furthermore, the form of the QRS complexes in lead V-1 might have been considered to be suggestive of right ventricular hypertrophy. That neither localized myocardial injury nor ventricular hypertrophy existed was supported by the form of deflections in a subsequent electrocardiogram dated April 19, 1954. The P-R interval had

reverted to normal, ventricular excitation occurred over the usual pathways and the ventricular complexes assumed a normal form. Recurrence of a short P-R interval in the record taken on May 27, 1954, was attended by reappearance of the peculiarities related to anomalous ventricular excitation.

The Fallacy of Half Truth

An ignorant genius may be no match for a well-informed fool.

A sound and time-honored dictum in teaching electrocardiography is the importance of taking sequential tracings during the acute phase of suspected myocardial injury. Once unequivocal electrocardiographic evidence of injury has been identified, the securing of additional records becomes a matter of lesser consequence. Judgment regarding clinical improvement and prognosis rests on evidence other than electrocardiographic.

The commonly emphasized necessity of securing adequate data at the time of suspected myocardial injury has a counterpart equally and obviously desirable but sometimes more difficult of accomplishment. When a patient presents an account suggestive of myocardial injury some months prior to initial examination by the physician currently in charge, when the currently recorded electrocardiograms are not diagnostic of injury, when the establishment of a diagnosis is important to patient and physician and when electrocardiograms taken at the time of occurrence of the suspected infarct are known to exist, these earlier tracings should be secured if possible. To do so may require patience, understanding and cooperation on the part of all concerned, but especially of the physician under whose supervision the earlier electrocardiograms were taken.

In Figure 3 are reproduced tracings illustrating the help to be had from review of records made during the acute phase of myocardial infarction. The patient was a forty-one-year-old man who did not have diabetes or hypertension.* He was subject to much anxiety, which led the clinician to reserve judgment regarding the presence of coronary sclerosis, although the patient's account was suggestive of angina pectoris. In the electrocardiogram dated September 17, 1956, tiny Q waves were present in leads II, III and aVF;

the T waves in leads V-4, V-5 and V-6 were inverted slightly in their terminal portion. This record does not afford evidence diagnostic of myocardial injury. However, on request, the physi-

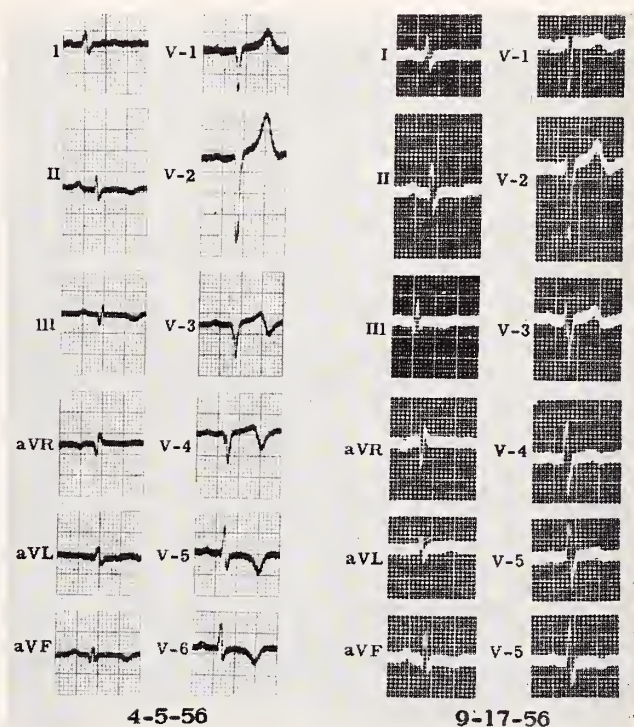

Fig. 3. The electrocardiogram of 4-5-56 affords diagnostic evidence of anteroapical myocardial injury. These changes no longer are evident in the record of 9-17-56.

cian who had attended the patient on April 5, 1956, was kind enough to send electrocardiograms of that date. These records provided diagnostic evidence of myocardial injury as manifested by absence of the R deflections in leads V-2, V-3 and V-4 and by deep inversion of the T waves in leads V-3, V-4, V-5 and V-6.

The Fallacy of Undiscerning Generalization

Like this; therefore the same as this.

The clinical applications of electrocardiography commonly rest on the proposition that complexes of a configuration known to bear consistent correlation with a specific myocardial lesion may be held indicative of the presence of that lesion. Errors in diagnosis occur in the event of (1) a faulty assumption of an unjustified correlation or (2) a rare exception to a usually valid correlation. Errors of the former type occur with decreasing frequency as data from experimental and pathologic laboratories accumulate to establish a sound foundation for clinical electrocardiography

*I am indebted to my colleague, Dr. T. W. Parkin, for supplying the electrocardiograms in this case.

and as clinicians become increasingly proficient in application of that knowledge. The chance of error consequent to the occurrence of a rare exception to a usually valid correlation remains to plague us.

cardiographic correlation was upheld, with that in the case represented by the tracings in figure 4b.* These records also were obtained from a young man, but he was free of symptoms of disease, cardiac or otherwise, and clinical exam-

Fig. 4. *a*. Tracings disclosing segmental and T-wave changes typical of acute pericarditis. *b*. Tracings from a patient without cardiac disease in which pronounced segmental elevation persisted unchanged in leads V-1, V-2, V-3 and V-4 for 9 months. See text for discussion.

Three pairs of electrocardiograms are reproduced in Figures 4, 5 and 6. In each instance, the tracings from one patient resemble closely those from the other patient in each pair, yet the myocardial lesions producing these similar electrocardiographic abnormalities were remarkably different in the individual members of each pair.

The tracings in Figure 4a were recorded from a twenty-seven-year-old man who had symptoms and findings characteristic of acute nonspecific pericarditis. The electrocardiogram dated December 24, 1950, showed segmental deviations typical of the acute phase of pericarditis. In the tracings dated three days later, sharply inverted T waves appeared in leads I, II, III, V-4, V-5 and V-6. This evolution of changes is usual in acute pericarditis, although the degree of inversion of the T waves is uncommonly great. Contrast this situation, in which a well-established clinicoelectro-

cardiographic correlation was upheld, with that in the case represented by the tracings in figure 4b.* These records also were obtained from a young man, but he was free of symptoms of disease, cardiac or otherwise, and clinical exam-

Figure 5 presents a second pair of cases with similar electrocardiographic findings. The tracings

*I am indebted to Dr. Monti Belot, 800 Massachusetts St., Lawrence, Kansas, for supplying me with the clinical data and electrocardiograms in this case.

in Figure 5a were recorded from a sixty-year-old man who had experienced symptoms typical of myocardial infarction two years prior to the date of the first set of electrocardiograms. The complexes in this set are of interest in that they

This fifty-six-year-old man had experienced pain in the lower anterior portion of the left side of the thorax and in the left upper quadrant of the abdomen two days after bilateral herniorrhaphy. The onset of this pain was attended by

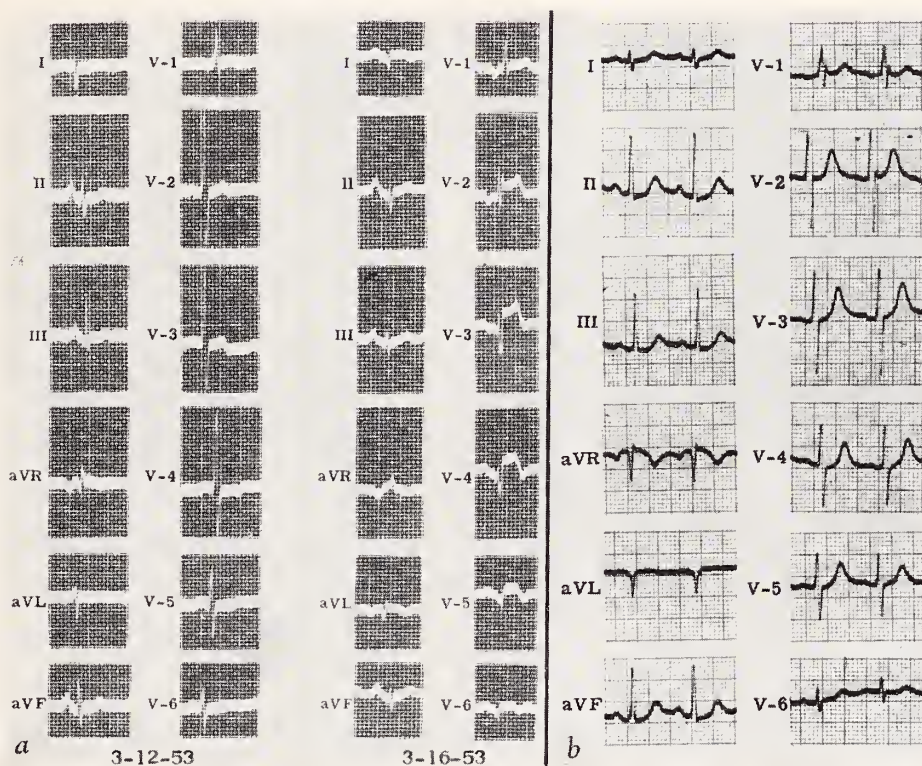

Fig. 5. *a*. The changes in the tracing of 3-12-53 were ascribed to the effects of an old transmural infarct of the posterolateral wall of the left ventricle. In the electrocardiogram of 3-16-53, changes have appeared related to an acute anteroapical infarct. *b*. Deformities of the ventricular complexes in this record were a consequence of partial right bundle-branch block.

suggest the presence of right ventricular hypertrophy. However, at necropsy after a second episode of myocardial infarction on March 16, 1953, an old transmural infarct of the posterolateral wall was found, together with an acute anteroapical infarct. That infarction of the lateral or posterolateral wall may be attended by the development of increased height of the R waves in leads from the right side of the precordium is an accepted fact. Such may have been the case in this instance, although a record made prior to the first infarct was not available to permit absolute judgment on this point. That an electrocardiogram of this form should not be regarded as affording conclusive evidence of infarction of the lateral wall in a patient whose clinical findings are of confusing character but raise justifiable suspicion of myocardial infarction is illustrated by the patient from whom the tracings in Figure 5b were recorded.

circulatory collapse that responded promptly to treatment. The patient's progress during the following week was satisfactory. However, on the ninth postoperative day, he had recurrence of pain and shock, and he died thirty hours later. Necropsy disclosed a postnecrotic ruptured aneurysm of the pancreatic artery, with intra-abdominal hemorrhage. No evidence of myocardial infarction, old or recent, or of pulmonary embolism was found. The peculiarities of the electrocardiogram presumably were related to partial right bundle-branch block.

The third set of confusing similarities is represented by the records in Figure 6. The tracings in Figure 6a contain the internal inconsistency of right axis deviation in the standard limb leads associated with evidence of left ventricular hypertrophy in the precordial electrocardiogram, an inconsistency dispelled by application of the concept

of the electrocardiographic disposition of the heart. One of my colleagues, Dr. H. B. Burchell, had predicted that rigid application of this concept might lead some day to discounting of changes related to myocardial infarction by ascribing them

Fig. 6. *a*. A tracing illustrating the effect of left ventricular hypertrophy with electrocardiographically vertical disposition of the heart. *b*. A tracing resembling that in *a*. The QRS changes in this case resulted from transmural infarction of the lateral wall of the left ventricle.

to an electrocardiographically vertical disposition of the heart. Although the error was avoided in this instance by reliance on other substantial clinical evidences of old myocardial infarction, such misinterpretation would have been understandable on the basis of isolated electrocardiographic evidence in the patient from whom the tracings in figure 6*b* were obtained. This sixty-three-year-old man was admitted to the hospital because of severe pulmonary edema. Treatment was of no avail and he died within a few hours. Necropsy disclosed a transmural infarct of the lateral wall of the left ventricle. Loss of myocardial mass, rather than an electrocardiographically vertical disposition of the heart, almost certainly contributed to the production of a QS deflection in lead aVL and the slight right axis deviation in the standard limb leads.

Illustrations of the pitfall of undiscerning generalization could be multiplied many times. Attraction to this pitfall is derived from the well-recognized temptation to overextend the interpretation of laboratory data in relation to clinical problems. Avoidance of error can be promoted if

the electrocardiographic interpretation is made in the light of other pertinent clinical facts. Segmental elevation, even though of unusual degree, will not be ascribed improperly to myocardial injury if the clinician is aware that the tracing was made

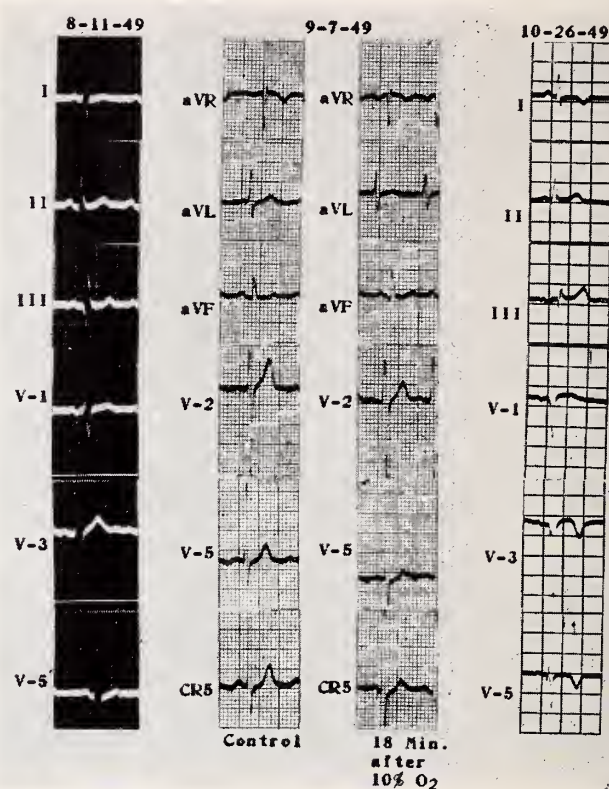

Fig. 7. The electrocardiograms on 8-11-49 and 9-7-49 were essentially normal despite clinical evidence of rather severe coronary insufficiency. Electrocardiographic evidence of myocardial infarction finally appeared in the tracing dated 10-26-49. See text for details.

on a young student in excellent state of health. A tall R wave in V-1 will be ascribed appropriately to right ventricular hypertrophy or, as the case may be, to infarction of the lateral wall of the left ventricle if consideration is given to other clinical data pertinent to rendering a discriminating decision. Likewise, careful appraisal of significant clinical findings will render unlikely the rigid or overly enthusiastic application of such a helpful concept as is represented in the influence of electrocardiographic position on the forms of the ventricular complexes in standard limb leads.

The Blind Faith That Makes Small Mountains

The electrocardiogram was normal, but the patient died.

One of the most treacherous of electrocardiographic pitfalls is related to the absence of change

in tracings taken from certain patients suffering from severe coronary insufficiency. Illustrative of this circumstance are the records reproduced in Figure 7. They were obtained from a thirty-nine-year-old man who had been experiencing during a period of five weeks episodes of severe pain extending over the front of the thorax and into both sides of the neck. These attacks had occurred both day and night, and their incidence was unrelated to physical activity. They commonly lasted thirty minutes or more unless nitroglycerin was taken, whereupon relief occurred within a minute or so. In spite of atypical features, strong suspicion existed that this patient's pain was an expression of coronary insufficiency. The electrocardiogram dated August 11, 1949, was considered to be within the range of normal. The Q deflection in lead III was unattended by a Q wave in lead II. A hypoxia test was done on September 7, during which the patient breathed 10 per cent oxygen for eighteen minutes. During this time, pain did not develop and his electrocardiogram remained unchanged. Because of increasing frequency and severity of the attacks of pain, the patient was admitted to the hospital on September 15. He was given a single, intravenously administered injection of aminophylline, grains $7\frac{1}{2}$, dissolved in 250 ml. of a 10 per cent solution of glucose. No more episodes of pain occurred from this day on, and dismissal from the hospital was permitted ten days later. After a month, the patient returned to report having had only two brief episodes of pain during the interim. The electrocardiogram at this time (October 26, 1949) showed changes diagnostic of antero-septal myocardial infarction, with inversion of the T waves in leads I, V-3 and V-5, loss of the R wave in V-3 and a qr deflection in V-5. In retrospect, the conclusion appeared well supported that the patient had experienced myocardial infarction during the hours immediately preceding his admission to the hospital on September 15. Because an electrocardiogram was not recorded at

this time, definition of the acute changes was not secured.

Significant is the fact that, even though careful electrocardiographic studies, including a hypoxia test, were carried out at a time when this patient was having severe and frequently recurring attacks of angina pectoris at rest, abnormalities of the ventricular complex were not recorded. Moreover, the patient did not experience an attack of pain when he breathed an atmosphere containing only 10 per cent oxygen for eighteen minutes.

An electrocardiogram, regardless of whether it is recorded in routine fashion, however elaborate this may be, or under conditions imposing stress on the heart, does not constitute a test whose negative results permit exclusion from further consideration of a diagnosis of coronary arterial disease.

Final Text

*"Because strait is the gate,
and narrow is the way . . .
and few there be that find it."*

In recalling this familiar Biblical admonition as an introduction to a final type of pitfall in electrocardiographic interpretation, my intent is not to discourage those who might aspire to mastery of this diagnostic technique; rather, I would encourage to new efforts some who failed in earlier attempts by reminding them that few among the many who try can master even the knowledge of their own day and hour. Advances in understanding, like the work of the world, are accomplished by those who can accept in good grace the mistakes and failures that beset their best and well-intended efforts. Therefore, the most treacherous of all pitfalls in electrocardiographic interpretation is the faint-hearted abandonment of efforts to make any interpretation at all, leaving that function to the remote and isolated expert, who may lack the clinical data essential to sound diagnosis.

HEARING IN CHILDREN

Different standards of hearing acuity are needed for the evaluation of different age groups below the adult level, Helen Kennedy, Ph.D., of Pasadena, California, reports from a study of children aged six through fifteen. A significant difference was found between the six and eight-year-old groups, and to a somewhat lesser extent between the eight and the fifteen-year-olds. The

"drop" in hearing acuity was found to occur most frequently at the twelve-year level.

"This would seem to indicate that the upper elementary grades may be a period of particular concern with regard to potential loss of hearing," the investigator said.

—*The Laryngoscope* (August) 1957

Prostatectomy in a Patient with Tetralogy of Fallot

J. S. ANSELL, M.D.
M. P. REISER, M.D.
Minneapolis, Minnesota

SEVEN cases of tetralogy of Fallot are reported, in which the patient lived beyond the third decade of life.¹⁻⁷ One patient had a laparotomy for gallstone ileus after the age of fifty. He expired on the seventh postoperative day with a wound dehiscence.⁷

Because of recent progress in surgical treatment of congenital cardiac disease, it is likely that many more such individuals will live longer and some may subsequently develop prostatic obstruction. It is our purpose to discuss the clinical course and special precautions observed prior to, during, and following prostatectomy in an individual with tetralogy of Fallot who survived to the remarkable age of fifty-six years.

Case Report

The patient, a white male accountant, was first admitted to the Urology Service of the University of Minnesota Hospitals on December 14, 1954, at fifty-four years of age. Three years previously, an episode of chills, fever, and dysuria had been successfully treated with antibiotics. Two months prior to admission, he noticed the onset of hesitancy, diminished force and size of the urinary stream, dysuria, postmicturitional dribbling, low back pain, pyuria and gross total hematuria. His symptoms were relieved by catheterization but not by antibiotics. He had noted mild exertional dyspnea all of his life. At the age of nineteen years he had an appendectomy and tonsillectomy without complications. Twenty-two years ago, he had been treated as an outpatient at the University of Minnesota Hospitals for acute dacryocystitis. At that time cyanosis and clubbing of the fingers and toes, a palpable thrill over the left second interspace lateral to the sternum, and a harsh systolic murmur, loudest in the pulmonic valve area but transmitted over the entire precordium, were noted. His blood pressure was 94/72; electrocardiogram was read as "arborization block and right ventricular preponderance." The hemoglobin was 105 per cent. He did well until the onset of his present illness.

The present admission examination revealed a short asthenic white man in no apparent distress; he weighed 132 pounds. The blood pressure was 110/80, the pulse

72. There was a peculiar inner ring of red pigment in both irises. The clinical examination of the lungs was normal. The heart was not enlarged; a thrill was palpated in the fourth left interspace close to the sternal border. The aortic second sound was slightly louder than the second pulmonic sound. A Grade IV systolic murmur heard over the precordium, loudest at the sternal border in the fourth left interspace. No abnormal abdominal organs nor masses were palpated; there was a right lower quadrant scar and no costo-vertebral angle tenderness. The fingers and toes were moderately clubbed and cyanotic. Neurologic examination was normal. The prostate gland was one plus enlarged, benign, and its profuse secretions contained numerous white blood cells. The residual urines varied from 85 to 180 milliliters.

Laboratory Studies.—Urine analysis: specific gravity, 1.020; pH, 6; sugar, negative; albumin, trace; sediment, 3+ wbc. The hemoglobin was 18.6 grams per cent, the white blood count was 5,150 with a differential count of 55 per cent neutrophils, 40 per cent lymphocytes, 1 per cent monocytes, 3 per cent eosinophils, and 1 per cent basophils. The blood urea nitrogen was 16 milligrams per cent. The urine culture contained *Bacillus proteus*. Cardiac fluoroscopy and pulmonary roentgenograms revealed a normal heart shadow and a normal pulmonary vascular pattern. The electrocardiogram disclosed a right bundle branch block. The excretory urogram was normal.

On July 13, 1954, following administration of 2,000,000 units of depot penicillin, a cardiac catheterization was done. The following data were obtained:

Sample	Pressure	O ₂	O ₂	
		Content	Capacities	
Right pulmon-ary artery	10.3/3.3	16.65	22.26	74.80
Left pulmon-ary artery	10.7/3.6	16.43	22.26	73.81
Pulmonary artery mean	6.0			
Right ventri-ple low	83.6/2.7	15.02		67.48
Right ventri-ple mean	23.4			
Right auricle mean	4.4	12.92		
Femoral artery		19.61		86.75
Superior vena cava		13.41		60.24

From Department of Surgery, Division of Urology, University of Minnesota Hospitals, Minneapolis, Minnesota.

Oxygen consumption plus 12.	188.91.	Basal metabolic rate	
		188.91	
Estimated systemic flow	10 (19.61—13.41)	=	
		3 liters / min.	
Estimated pulmonic flow	10 (19.61—16.53)	=	
		6.1 liters / min.	
Estimated shunt left to right	3.1 liters / min.		

Summary of Cardiac Catheterization.—Anatomic tetrad with evidence of both right to left and left to right shunts, being predominantly left to right shunt at rest. Actual shunts cannot be calculated because of mixing and simultaneous shunt in both directions. The ventricular sample was taken at ventricular apex and therefore is not representative of blood in the outflow tract.

Clinical Course.—Cystourethrogram revealed a Grade I enlargement of the prostate gland and an atonic bladder; subsequent cystoscopy utilizing intraurethral cocaine anesthesia confirmed this diagnosis. Prostatic massages and antibiotic therapy with tetracyclines afforded slight temporary relief of his symptoms.

On February 8, 1955, a trocar cystostomy was done. He received 500 mg. of tetracycline the evening before and again on the morning of the procedure, and 250 mg. of tetracycline four times a day for the next two weeks. Despite four months of cystostomy drainage and a course of prostatic massage, when the cystostomy tube was clamped, the residual urine varied between 120 to 240 milliliters. It was felt that a prostatectomy was indicated. For two days preoperatively, he received penicillin 500,000 units every six hours and tetracycline 500 mg. twice a day.

On February 22, 1955, under spinal anesthesia, eleven and one half grams of prostatic tissue were excised transurethally with a blood loss of 136 milliliters. The pathologist reported benign prostatic hypertrophy. Postoperatively his temperature remained normal except for a rise to 100.4 degrees a few hours after the operation. Penicillin 500,000 units four times a day and tetracycline 250 milligrams four times a day were continued postoperatively. On the third postoperative day, the urethral catheter was removed and the cystostomy tube was clamped. The residual urine which at first was low, progressively increased despite the use of cholinergic

drugs. On June 17, 1955, four grams of prostatic tissue and a wedge of the trigone were excised transurethally with a blood loss of 72 milliliters. On the first postoperative day, his temperature was 100.6 but subsequently remained normal. The urethral catheter was removed on the third postoperative day and the suprapubic tube clamped the following day. He voided satisfactorily with residual urines of 0 to 15 cubic centimeters. The postoperative blood and urine cultures were sterile, but he was receiving antibiotics. His hospital convalescence was essentially uneventful except for a slight hemorrhage on the twelfth postoperative day. The cystostomy tube was removed on July 12. The vesical neck has been periodically dilated in the outpatient clinic. As a precautionary measure he receives 500 milligrams of tetracycline the night before and the morning of dilation. He has gained weight and has continued to work up to the present time.

Summary

A fifty-six-year-old white man with a diagnosis of tetralogy of Fallot made by clinical examination and cardiac catheterization has had three operations for prostatic obstruction. This is the first reported case of a patient with tetralogy surviving a surgical procedure in the sixth decade of life.

AGE AND ABSENTEEISM

An analysis of absenteeism among 619 workers in a Greater Boston food processing plant showed that both frequency and disability rates decreased with age, according to a study by the Gerontology and Chronic Disease Unit, Department of Public Health Practice, Harvard School of Public Health.

"The statistical record clearly supports a positive find-

ing that the absence experience of workers forty-five and over does not compare unfavorably with that of workers under forty-five," the investigators concluded.—H. R. Kahne, C. M. Ryder, L. S. Snegireff, and G. Wyshak: Age and absenteeism, *A.M.A. Archives of Industrial Health*, 15:134 (Feb.) 1957.

Preoperative Roentgen Diagnosis of Abdominal Tumors in Children

ALEXANDER R. MARGULIS, M.D.
CHARLES M. NICE, JR., M.D., Ph.D.
LEO G. RIGLER, M.D.
Minneapolis, Minnesota

IT IS still the policy of many physicians to adopt an attitude of surrender when faced with the preoperative diagnosis of abdominal masses in infants and children. Many of these physicians still believe that it is wasteful to lose time and spend the patient's family's money on roentgen studies and would rather leave the task of diagnosis to the surgeon and pathologist.

Such reasoning is fraught with rather obvious dangers and pitfalls. Physical diagnosis and history alone usually can only establish the presence of a space-occupying lesion. If left to such methods alone, one can only conclude that the mass is in the abdomen. Its extent, its location, and its nature cannot be made out. A correct preoperative diagnosis has many advantages. If it is concluded that a lesion is within the kidney, the case may be handled better by a urologist than a general surgeon. A retroperitoneal mass will require a different surgical approach than an intraperitoneal tumor. Some masses should have biopsies done only to confirm the roentgen diagnosis, and then irradiated rather than surgically removed. If correctly localized and diagnosed, some space-occupying lesions will be best treated if no operation is undertaken. It has been our experience occasionally that a correct preoperative diagnosis will not only guide the surgeon in his search for the tumor, but will also give him the necessary stimulus and assurance to persist at time of operation in the search for an elusive lesion in a region of difficult access. It is rather paradoxical that there should be such general emphasis on accuracy in diagnosis while an approach of defeatism is adopted in such a wide field; that there should even exist an argument whether one should attempt to exactly localize and identify a mass in a child's abdomen.

It is the purpose of this writing to present a roentgen method which is based on simple, rather

routine procedures commonly done in all hospitals and even offices. By using this roentgen approach and evaluating the findings in the light of history, physical findings, and the patient's age, sex, and laboratory information, a correct preoperative diagnosis based on statistical probability can be made in a high percentage of cases.

A systematic approach to the roentgen diagnosis of abdominal masses in general lagged somewhat behind the progress in other fields. While the opacification of the gastrointestinal tract followed the discovery of x-rays only by a relatively short time, it was not until 1923 that a method for discovery of masses by their displacement of the opacified gastrointestinal structures was described.¹ Brown emphasized the importance of the lateral view in 1928.² Rigler in 1933³ devised a classification based on location, using routine gastrointestinal contrast studies as well as pycelography. He also emphasized the use of lateral views. Rose⁴ and later McCullough and Sutherland⁵ wrote on intra-abdominal calcification and its significance. An extensive elaborate monograph exists in Spanish⁶ dealing with the topographic study in the diagnosis of abdominal tumors in adults. Nice et al.,⁷ produced a monograph dealing more fully with the method described in this presentation.

We believe that the first step in the roentgen diagnosis of an intra-abdominal mass should be its exact location. Is the mass within the peritoneal cavity or is it extraperitoneal? Is it located within an organ or is it in the supporting tissues? In order to answer these questions, advantage is taken of several easily identifiable landmarks.

In the course of the development of the intestinal mesentery and the gastrointestinal tube, the dorsal mesentery of the duodenum and the mesentery of the ascending and descending colon become attached to the posterior abdominal wall and become obliterated. As a result of this, the second portion of the duodenum as well as in most instances its third portion, the descending colon, the ascending colon and the rectum have no mesentery. The upper rectum as well as the other

Fig. 1. Primary hepatoma in a five-month-old male infant. (a) A soft tissue mass inseparable from the liver (black arrows) but clearly defined from the right kidney (white arrows) is seen in the right upper abdomen. (b) The right kidney is depressed slightly but normal. (c) The mass displaces the stomach anteriorly. The second portion of the duodenum (black arrows) and the duodenojejunal junction (white arrow) are in normal position indicating that the mass is intraperitoneal.

structures described are covered in front and on the sides by the parietal peritoneum and lie against the posterior abdominal wall. The pancreas, too, assumes a retroperitoneal position as does the distal part of the common duct. Usually a duodenojejunal junction can be identified easily, especially on contrast studies, and is attached to the posterior abdominal wall by means of the ligament of Treitz, a fixed structure. The bladder has a peritoneal covering over its dome, but is an extraperitoneal structure. The kidneys and ureters, also structures readily recognized, are retroperitoneal. The liver, spleen, and stomach are enveloped by the visceral peritoneum, except for minor areas of their surface. The small bowel except for the duodenum, and the transverse colon and sigmoid, are suspended on their mesentery along which the parietal peritoneum reflects to cover the mesentery and the bowel wall, thus forming the visceral peritoneum. Occasionally, variations of this typical arrangement occur, but these are easily understood as phases of arrest in the rotation of the bowel and obliteration of the mesentery, and, once identified, can also be used in localization.

Using the structures described, and their rather fixed location, a series of landmarks is established. By outlining the duodenum and the duodenojejunal junction with barium and studying them in frontal and lateral projections, it can be readily recognized that a retroperitoneal mass in the region of the head of the pancreas, or behind it,

will widen the duodenal loop in frontal projection and displace the second portion of the duodenum forward in the lateral projection. The duodenojejunal junction will be unaffected. A cystic dilatation of the common duct, a choledochal cyst, if small, will cause an impression on the second portion of the duodenum, and, if large, will also displace it forward in lateral view without widening the duodenal loop in frontal projection. It usually will displace it medially. Similarly, a right upper quadrant intraperitoneal mass, such as hepatoma of the right lobe of the liver⁸, while located in the same general area in frontal projection, will displace the landmarks that are fixed immediately behind the parietal peritoneum posteriorly.

A retroperitoneal mass in the central upper abdomen, such as a cyst of the pancreas or a tumor of sympathetic nervous origin, will displace the duodenojejunal junction forward, and usually downward, while separating the stomach from the transverse colon. The stomach will be pushed forward in the lateral view. Intraperitoneal masses in this region, a hepatoma of the left lobe of the liver, for instance, will displace the stomach to the left, and forward or posteriorly, but the duodenojejunal junction will not be displaced anteriorly. The ascending or descending colon will also be displaced forward by a retroperitoneal mass that arises laterally while they will be impressed on their anterior surface by intraperitoneal masses. One should remember, however, that, if there is

partial malrotation of the colon with preservation of a mesentery of the ascending colon, this structure may be displaced forward by an intra-

Lateral displacements near the kidney are a sign of extraperitoneal location of the lesion. Anterior displacement of the ureters, as seen in lateral

Fig. 2. Wilms' tumor of the right kidney in a six-year-old girl. (a) A large soft tissue mass is present in the right abdomen displacing the small bowel including the duodenum. It is inseparable from the right kidney. (b) Excretory pyelogram. There is distortion of the calyces and the right renal pelvis. The uretero-pelvic junction and the entire upper ureter are displaced medially.

peritoneal mass, as, for instance, a mesenteric cyst.

The rectosigmoid junction has a constant position near the sacrum. It is from there that the mesosigmoid arises, and the sigmoid itself has a variable course according to its length. In lateral projection, an intraperitoneal lesion will be seen either not to affect the junction at all, or it may impress it downward and on its anterior surface, or occasionally even displace it posteriorly, according to its size. A retroperitoneal tumor will displace the rectosigmoid junction anteriorly, away from the sacrum.

The transverse colon is suspended on its mesentery and, therefore, is quite movable. Intraperitoneal masses may displace it anteriorly or posteriorly according to their location. We have encountered a case of hepatoma in which the transverse colon could be seen wrapped around the tumor. An omental cyst will usually be seen to displace the transverse colon posteriorly, a mesenteric cyst anteriorly.

The ureters can be displaced laterally, as seen in frontal projection, by either an intraperitoneal or extraperitoneal mass, depending on its size. This is especially true in their lower two-thirds.

projection, is usually due to a retroperitoneal lesion. Conversely, a posterior displacement usually is caused by an intraperitoneal mass.

A neuroblastoma or other adrenal mass will displace the kidney downward and quite frequently laterally. Anterior displacement also is not rare. Posterior displacement of the kidneys, often combined with downward displacement and compression, is commonly caused by tumors of intraperitoneal location such as mesenteric cysts or hepatomas. This is not an absolute sign, however, as choledochal cysts which are retroperitoneal can produce the displacement.

The ureteropelvic junction is an important landmark; when displaced medially in frontal projection, it usually signifies that the mass is within the kidney. Large masses almost anywhere within the kidney will produce this appearance, with the exception of a lesion that is limited to the medial aspect of the upper pole. A central retroperitoneal mass will displace the kidney to the side and will move the ureteropelvic junction laterally.

The bladder has to be outlined by opaque medium before one can make positive statements as to a displacement upward from the pelvic floor. In cases following trauma and pelvic fracture,

this displacement is most frequently due to a hematoma. Without such history, in the male the cause is usually a tumor of the prostate, and

peritoneal location in a child with known neuroblastoma is usually an indication of metastatic spread. Certain types of calcification and the

Fig. 3. Neuroblastoma with multiple bony metastases in a four-year-old boy. (a) There is extensive calcification in the region of a suprarenal mass on the left. (b) Excretory pyelogram. The left kidney is depressed and displaced laterally. The ureteropelvic junction is displaced laterally.

sarcomas of the prostate are more common in childhood. Ovarian or dermoid cysts will usually cause an impression on the bladder dome.

While displacements of landmarks will be of great importance in determining the location of the tumor, of equal importance is the attempt to outline the limits of the mass and establish whether it is single or multiple. One should also use frontal as well as lateral and, if necessary, oblique projections to determine whether the mass lies within the limits of an organ, such as the liver, spleen, or kidney. The outline whether regular, round, or undulating, indicating nodularity, often distinguishes between a cystic structure and a solid malignant tumor.

Calcification and its pattern is frequently of great importance. Often calcification will indicate the presence of a mass that otherwise would be obscure. We have had cases of adrenal cortical tumors and small neuroblastomas in which the presence of calcification was the only localizing sign. A stippled irregular area of calcification in a growing mass in the liver is usually seen in hepatoma. New areas of calcification in retro-

appearance of formed structures are seen only in teratoid masses. They may be intraperitoneal, if of ovarian origin, as many dermoid cysts are, or retroperitoneal. Some of the retroperitoneal teratomas may be highly differentiated and even present the appearance of fetus *in situ*. Calcifications within cysts can also be demonstrated to move around with change in position. Advantage can also be taken of the layering property of the fatty content of a dermoid cyst, if the film is taken in upright position.

In examining a mass, information can be gathered also from areas distant from the tumor. Advanced maturation as determined by early appearance of epiphyses can be a sign of an adrenal cortical tumor. The greater and lesser trochanters can be helpful as they are frequently included in films of the abdomen. Similarly, evidence of mediastinal and hilar adenopathy or presence of bone destruction may give valuable identifying information.

The method described is based on the use of plain films of the abdomen with frontal and lateral projections believed to be essential. The

upright position is frequently valuable. The upper and lower gastrointestinal examination with barium with the use of lateral projections is neces-

statistical probability, taking the patient's age and sex into account, one's diligence will usually be rewarded.

Fig. 4. A teratoma with neuroblastoma in a two-day-old female infant. (a) A large soft tissue mass displaces the rectum to the right and the small bowel out of the pelvis. The arrow points toward a bony density in the mass, a tooth identifying the tumor as a teratoma. (b) The rectum (with the tube) is displaced forward indicating that the mass which extends below the coccyx has a retroperitoneal extension. The whole intestine is pushed forward. Arrows point toward calcifications in the mass.

sary for precise identification of many of the landmarks discussed. Urography, excretory and, if necessary, retrograde, should be obtained for localizing purposes also in masses that are outside the urinary tract. Cholangiography and cholecystography are rarely needed, but in certain isolated cases may be of value. It is unfortunate that these procedures do not give visualization of structures when most needed, as in the cases of choledochal cysts.

It is interesting to note that these rather commonplace studies are usually all that is needed in the radiographic work-up. The use of more elaborate procedures, such as planigraphy and presacral gas injection, are refinements that are unnecessary in the great majority of instances. If all the information from the roentgenograms as to location, size, outline, content, is correlated with data from the history, physical examination and other laboratory examinations, and all of these facts are evaluated in the light of available

The Patient's Use of Gestures in the Diagnosis of Coronary Insufficiency Disease

WILLIAM B. MARTIN, M.D.
Duluth, Minnesota

PAIN in the chest is one of the most frequent complaints the doctor hears. The difficulty in determining the cause of this pain is attested to by the number of articles on the subject, and by the great number of consultations requested on this diagnostic problem. The difficulty is further emphasized by the recent description of the carotid sinus pressure maneuver which may promptly relieve the pain of acute coronary insufficiency and permit its rapid identification. It is significant that a cardiologist of great experience would find this new test useful.¹

The diagnosis of coronary disease is best understood by a division into three syndromes. Each has its distinctive symptomatology, pathologic connotations and therapeutic program.

The easiest to understand, since pathologic material illustrating it is so plentiful, is acute myocardial infarction usually occasioned by coronary thrombosis. Generally speaking, in this disease the pain is severe; it is associated with impressive systemic manifestations and sooner or later with diagnostic electrocardiographic changes in at least 80 per cent of cases.

The second form of coronary artery disease that concerns us is angina pectoris. Angina usually gives rise to a pain or discomfort that is transient, episodic and recurrent; usually, it is not associated with constitutional symptoms, and it is not accompanied by diagnostic electrocardiographic findings. If an abnormal electrocardiogram is found, it is not pertinent to the diagnosis of angina, but does counsel restraint in dismissing the pain as not coronary engendered.

Coronary insufficiency, or so-called "coronary failure," or "the intermediate coronary syndrome," is a diagnostic term describing a condition myocardial in origin, in which the pains are longer in duration and more severe than in angina. In this condition, clinical, hematological, enzymatic, and electrocardiographic criteria of myocardial infarction do not develop. Its pathological physiology is usually stated to be an ischemia or ne-

crosis of the myocardium and, in particular, of the subendocardial muscle layers. Coronary insufficiency can be secondary to some other condition; for example, anemia due to a primary blood condition or to hemorrhage, most often from the gastro-intestinal tract. Coronary insufficiency is an important diagnosis because it may be a premonitory symptom of myocardial infarction.

These three syndromes are in most instances due to coronary atherosclerosis. Valvular heart disease, aortic stenosis or regurgitation, and luetic aortitis often first announce themselves with chest pain, but are numerically much less important causes.

While the nomenclature may be confusing, it is simpler to call the pain originating from each of these three conditions "coronary insufficiency pain" and include under it myocardial infarction, angina pectoris, and, what is generally termed in the literature, coronary insufficiency.

This classification is based on present concepts and is simple and workable. The simplicity vanishes when the physician encounters the patient who does not have classic symptoms or findings.

Prior to discovering what will be related herein, I leaned, as have others, on a verbal interpretation of the pain. As in other fields, the analysis of the pain, when present, is the keystone of the diagnostic arch. The patient relates his story, suitable questions are asked, and specific points are checked. In angina, the physical examination and the laboratory tests are not helpful. The same paucity of physical and laboratory findings may exist in the first two to twenty-four hours of myocardial infarction. This is an important point not frequently emphasized. The history in this early period may be of crucial importance.

There are other problems in the diagnosis of chest pain in the ambulatory patient. The patient with chest pain is often unable to be as helpful as we wish. He may be a poor observer or he may not be capable of explicit answers. He may

have two kinds of chest pains coexistent which he has never separated in his own mind. Other shortcomings of the verbal method of examination are language difficulties and verbosity. Cer-

Fig. 1. This illustrates gestures Number 1 and Number 2. Number 1 involves the transverse sweep of the flat of the hand across the upper chest. Number 2 is the static placement of the hand over the sternum.

tainly, it is true that sensations of the body often outstrip vocabularies. The practitioner, mindful of the number of conditions that cause chest pain and that mimic angina in part, may terminate the interview by ordering an electrocardiogram and the diagnosis becomes more clouded.

Awareness of Gestures

About two years ago, it appeared to me that patients suffering from "coronary insufficiency pain" frequently used their hands to indicate the location and severity of their discomfort. I developed the habit of taking a few minutes more with them after the diagnosis seemed secure and of having them re-enact their pain description. Certain similarities became apparent. In talking with patients having chest pain related to other conditions, it appeared that the gestures used by the cardiac patient were not frequently used by noncardiac patients. In certain instances, the gestures used by cardiac patients were so spontaneous and so identical to those seen in others that I began to feel they might have diagnostic significance or, at the very least, provide a clue to alert the observer and to induce him to pursue a certain line of questioning or investigation.

A review of the texts, monographs and current articles on the diagnosis of coronary artery dis-

ease showed slight regard for gestures used by patients to describe their sensations. There were two exceptions to this. White² stated that patients with angina often lay the flat of the hand on the

Fig. 2. This illustrates gestures Number 3 and Number 4. See text for details.

mid-sternum to indicate their pain. Levine³ mentioned the half-closed hand placed on the mid-sternum and moved by the patient upward to the throat, or bilaterally to the jaws, as a nearly diagnostic gesture of coronary disease pain.

It is my contention that there are certain mannerisms and gestures commonly used by those suffering from coronary insufficiency pain, used in the sense defined above, that, when seen, can alert the physician at once to the likelihood that a discomfort complained of is of serious import. I call this concept the "nonverbal diagnosis of coronary insufficiency pain."

To describe any gesture thoroughly one should include several features. For example: a gesture involves placing the hand or fingers in a certain position on the body, it includes the position of the hand in relationship to the fingers and, finally, any motion that the hand might describe.

In coronary insufficiency pain, six gestures or portions of gestures are used with sufficient frequency and similarity to constitute an aid to diagnosis.

Description of the Gestures

1. *The Flat Sweep* (Fig. 1).—The flat of the hand, usually with the fingers not widely separated, is placed on the mid-line of the body on the sternum at the level of the first intercostal space or down to the fourth rib line. The hand is then lightly swept across the chest from far left to far right, or vice versa, usually with an

quidistant swing bilaterally in a strictly horizontal plane. The fingers are not pressed into the chest, nor is the hand stopped at any point in the sweep.

Fig. 3. Gestures Number 5 and Number 6 commonly seen in ischemic heart disease are depicted.

2. *The Flat Placement (of White)* (Fig. 1).—

The flat of the hand is laid on the chest in the mid-portion of the body anywhere between the first intercostal space and the fourth rib line, but there is no movement of the hand when so placed. This is the gesture described by White.

3. *The Two-Handed Press* (Fig. 2).—

The pads of the fingers are laid at the midpoint of the chest on the sternum somewhere between the first intercostal space and the fourth rib line, and then separated in a horizontally sweeping motion, completely or partially across the front of the chest again in an equidistant manner bilaterally, both hands being used.

4. *The Two-Handed Squeeze* (Fig. 2).—

A variant of the third gesture is the placing of the hands at about the anterior axillary line bilaterally and moving medially so that they meet in the midline, again the hands moving in a horizontal plane.

5. *The Reverse Necktie* (Fig. 3).—

The fingers of one hand or the other are flexed in a semi-clutched position, a sort of half-fist appearance, and the hand is then placed on the midsternum, again, anywhere from the first intercostal space level to the fourth rib level. This placement of the hand is then followed by a gesture often accompanied by a tighter squeezing of the fingers to a full fist appearance and by a vertical motion

TABLE I. GESTURES USED BY PATIENTS WITH CORONARY DISEASE

	No. Cases	Gestures Used						Total Gestures	Per Cent
		1	2	3	4	5	6		
Myocardial Infarct	14	7		2		3		12	83
Coronary Insufficiency	28	4	3	2	2	4	2	17	61
Angina	40	4	9	2		3	2	22	55

Note: Table I summarizes the frequency of the gestures used in different types of ischemic heart disease.

up towards the throat or to the lower jaw. At other times, the hand opens as it ascends to include both sides of the throat or both lower jaws.

6. *The Midline Clutch* (Fig. 3).—This is the same as above without the addition of the motion of the hand. It refers to the placement of the hand in a semi-clutched position, in the midline in the areas described.

Cases Observed

The group of cases that I have considered in respect to the gestures are summarized in Table I.

The series on myocardial infarction is small, perhaps because the diagnosis is usually quite evident on other grounds, and the details about the pain description were not recorded. At any rate, of the fourteen cases, seven of them used gesture Number 1 and twelve of the fourteen 83 per cent, used one or the other of the gestures which have been described. In coronary insufficiency I feel that the gestures are often seen in their most typical form, in particular, those which have been occasioned by hemorrhage. The group includes twenty-eight patients, seventeen of whom used one or the other of the gestures. Forty patients diagnosed as having angina have been interviewed with the idea in mind of identifying the location of the pain and gestures used. Approximately one half (55 per cent) have used the gestures in the forms described. All of these patients were seen by me personally.

Initially, patients with angina would frequently refuse to indicate by a gesture where their pain was. However, when asked specifically to indicate the pain, they all did, in some way, attempt a gesture. I think that when the patient does attempt a gesture after prompting in this way, the diagnostic significance is less than when he uses a gesture which is a spontaneous concomitant of the sense of his idea. In myocardial infarction, spontaneous typical gestures are often used by

the patient in preference to talking about his pain. In angina, on the contrary, the patient must often be asked pointedly to demonstrate his pain. It is as though the anguish of severe pain causes people to revert to the more primitive method of communication by gestures. Indeed, not uncommonly in infarction, the severity of the pain may be gauged by the repetition of certain of the gestures. One fatal case repeated gesture Number 1 six times before speaking a dozen words about his condition.

I wish to emphasize that the absence of a typical gesture by no means establishes that the patient does not have coronary disease. Obviously, other features of the history are of importance and, in infarction, electrocardiographic and other laboratory aids are of benefit. However, these gestures are used with considerable frequency, perhaps 50 per cent of the time, by persons who are suffering from one of these three conditions. If the gestures are seen in their pure form and spontaneously used by the patient, I think they are a diagnostic clue of considerable importance.

As I became more interested in this I related my feeling about it to some other physicians and three interesting stories were later told to me. One physician was called to the home to see an older lady because of chest pain. The lady minimized the discomfort and thought her relatives were unduly apprehensive. My physician friend examined her and found nothing striking on the physical examination. There was no change in a previously known moderate hypertension, no change in heart tones, no gallop rhythm, and no evidence of congestive failure. He was inclined to leave her, as she had been in bed, and not be particularly concerned about her episode of chest pain. However, he waited a moment longer and asked her, "where does it hurt?" She promptly performed, in its classic form, gesture Number 1. The physician then insisted on hospitalization and an electrocardiogram that evening showed an unmistakable myocardial infarction pattern.

Another instance I am not certain I wish to emphasize happened this way: I had described the gestures which I have portrayed to a practitioner acquaintance. He had a patient under his care who had been indicating his pain as epigastric in location and predominantly abdominal in type. However, this man was known to have heart disease, in particular, an old infarction. This new pain, while other criteria were

lacking, was felt by his physician to indicate an acute coronary disease process. Because the gesture which the patient was using was in marked contrast to the gestures which I had been describing for coronary artery pain, the physician was induced to investigate the matter further and discovered a peptic ulceration and penetration, for which suitable treatment produced relief of the man's persistent complaint.

A third instance of the use of the gestures has been related to me. A patient was brought to the emergency room of a local hospital with a history of having swallowed a fish bone, and with chief complaint of the fish bone lodged in the esophagus. He indicated his pain as in the midline, and in fact, used gesture Number 5. He was initially referred to an endoscopist with the intent of removing the foreign body. The endoscopist, however, aware of the gesture description from a recent discussion of them, was greatly impressed with the classic form of the gesture being used. As a result, an internist's consultation was obtained and electrocardiographic studies ordered with the eventual diagnosis of an acute myocardial infarction. The fish bone was felt to be an incidental occurrence and it actually passed spontaneously without instrumentation. In this instance, even the presence of a foreign body in the esophagus did not prevent the classic gesture from appearing and the alertness of the endoscopist to lead to the correct diagnosis.

False Positives

Of importance is the possible use of these gestures by people who do not have coronary disease.

In two instances, people with acute cholecystitis used gesture Number 3. In fact, they used the gesture in such a recognizable form that I was initially suspicious that they had coronary disease. However, eventual evaluation led me to feel their difficulties arose in the gall bladder. Of course, the question as to the origin of chest pain in cholecystic disease has been debated in the past. There is one interpretation that it is entirely a referred pain; the other theory is that the cholecystic disease sets up a coronary spasm which does induce coronary insufficiency pain. The close similarity of the gestures used in these two patients with cholecystitis would tend to favor the theory that actual coronary constriction was occurring and that these people did in actuality have cor-

nary insufficiency. They have not been included in that category in the table.

Whether or not people with other types of

Fig. 4. This is a common gesture in non-cardiac pain, namely the costochondral syndrome.

chest pain will mimic these gestures I am not prepared to say with finality. It seems to me that they do not. The chest is not a particularly large area, and the hands, relatively speaking, are fairly large so that in a person who is given to a good deal of gesticulation certain positions might be momentarily assumed which are similar to those described. The significant gestures are more of a distinct movement on the part of the patient, frequently a repeated movement, not associated with other motions about the chest. Of course, the gestures are meaningful only when used to depict pain or discomfort.

In nervous people, particularly females who indicate their pain in various ways and who are accustomed to moving their hands about a good deal to indicate how they feel, I have some times seen portions of the described gestures. Another feature about these individuals in their use of gestures is the frequency of diagonal positions. They do not usually lay one hand or both hands across the chest transversely or sweep the hands in a strictly horizontal plane, as do patients with coronary disease.

Gestures in Non-Cardiac Chest Pain

There are other gestures used by people without cardiac disease, which are quite distinctive. A very frequent complaint is pain of the chest wall. Frequently this is in the intercostal areas and in the areas of the costochondral junctions. These people with chest wall pains, or the costochondral syndrome, will usually indicate the pain with the tips

of the fingers, generally held at a right angle to the chest, in the area of the left sternal border or laterally in the area of the costochondral junction.

Fig. 5. The hand is often placed in this manner when the patient is describing the sensation of pain originating from the colon.

tions. They frequently dig the fingers into the chest in their attempts to portray the sensation, (Fig. 4), a rather distinct contrast to the type of gestures which have been described for coronary disease pain.

Another very frequent cause of pain in the chest appears to originate in the colon with radiation into the chest. When this is primarily in the left upper quadrant it is often referred to as the splenic flexure syndrome. People with this condition often indicate their pain far on the lateral margin of the chest near the costal margin and often radiating up toward the axilla or toward the middle of the chest. They often use the entire hand in a grasping motion or put the hand in the form of a cone and direct it upward from the colonic area (Fig. 5), in contrast to the gestures described earlier in this paper.

Individuals who have palpitation often indicate their discomfort in the left lower lateral chest area about the fifth, sixth, and seventh rib level extending from the midclavicular line to the mid-axillary line. They often use the entire palm in a grasping motion in this area, frequently at the same time saying, "This is where it hurts, right over my heart."

The observation of gestures in other types of chest pain is useful in the discussion with the patient and in explaining to him that something other than the heart is causing his pain. The

The Establishment of a Blood Vessel Bank

Sterilization of Vascular Homografts Using Beta-Propriolactone

THOMAS O. MURPHY, M.I.
Tacoma, Washington

JERRY ROSENBERG, M.I.

RICHARD L. VARCO, M.I.
Minneapolis, Minnesota

CONSIDERABLE progress in vascular surgery has been made during the past decade, particularly in the treatment of aneurysms and segmental arterial occlusions. These newly developed procedures have often required blood vessel substitutes from vein autografts,¹ vascular prostheses² or arterial homografts. However, many community hospitals have not been able to maintain an adequate supply of the latter because of difficulties encountered in obtaining and preserving sterile homografts. Currently, techniques are available which should make it possible for hospitals to establish and maintain a blood vessel bank.³ It is the purpose of this paper to outline the methods used in the procurement, sterilization and preservation of blood vessels for arterial homografts using beta-propiolactone. In our experience, this method seems well suited for hospitals even in a smaller community.

Rationale of Technique

The drawbacks to obtaining homografts under sterile conditions are obvious. To overcome these handicaps, physical and chemical sterilizing procedures have been worked out which permit materials to be collected during a routine autopsy and then subsequently be sterilized and utilized as a vascular substitute. The use of beta-propiolactone*, a sterilizing agent, as developed for this purpose by a group of workers at the Henry Ford Hospital in Detroit,⁴⁻⁸ serves admirably in this regard. It is an internal ester of beta-hydroxy propionic acid and is extremely active due to the tendency of the ring to open.⁹ It is very toxic and caustic, acting as a sterilizing agent by combining with hydroxy, amino, carboxyl, sulfhydryl

and phenolic groups of protein molecules. Its potent bactericidal, virucidal, fungicidal and sporicidal effects have been well demonstrated.⁹ The products of hydrolysis, which must occur for the beta-propiolactone to exert this effect, result in compounds which have been shown to be non-toxic but of a low pH. The effect of this agent on the elasticity and tensile strength of the graft is not significant if the acidity of the sterilizing solution is kept near a pH of 7.4. In aqueous solutions the half-life of beta-propiolactone at 37° C. is thirty to forty-five minutes (Fig. 1). However, when stored in the pure concentrated form in a refrigerator at 4° C., it is stable for ten months.

Method

The graft to be sterilized should be obtained as soon after death as possible. An interval of less than six hours is considered quite safe, although if adequate refrigeration has been used, the vessels can be successfully transplanted up to twelve hours after death. Preferably, the donor material is obtained from a patient under the age of forty-five but the degree of vascular degeneration in each instance must be individually evaluated. Certainly, patients dying of atherosclerotic processes or collagen diseases should not be used. In obtaining the graft, excessive contamination should be avoided, particularly from gastrointestinal contents, and in this regard it is wisest to procure the blood vessels at the start of the post mortem. They are rinsed in saline, trimmed of fat and extraneous tissue, leaving the adventitia intact, and then sterilized as outlined below after a minimum of delay.

A long forceps and the empty pyrex jars to be used to sterilize, rinse and store the grafts are thoroughly cleaned and then sterilized by autoclaving. Satisfactory jars are those in which suture material comes (Fig. 2). Strict technique, in-

cluding the wearing of a surgical mask and the use of only sterile solutions, such as that used in the operating room or bacteriologic laboratory, is necessary throughout.

Half-life of beta-propiolactone in water at different temperatures.⁹

Fig. 1. The half life of beta-propiolactone in water at different temperatures.⁹

The following basic solution is prepared:

0.9% (physiologic) Saline.....	500 cc.
Sodium bicarbonate.....	8.4 gms.
Phenosulfonphthalein (Phenol red)	12 mgm.

Since a bicarbonate solution cannot be autoclaved for sterilization, a solution of sterile bicarbonate containing 3.75 gms. NaHCO_3 in 50 cc. of distilled water, sealed in glass ampules as is readily available from commercial drug houses,* is used. Approximately 400 cc. of sterile saline are poured into the sterile jar and two 50 cc. ampoules of bicarbonate and six ampoules of phenol red indicator are added.

To this solution are added 4.4 cc. of beta-propiolactone, measured with a syringe. The graft

to be sterilized is immediately placed in this mixture and that stirred so the entire flask is coated with the solution. This solution now contains one per cent beta-propiolactone by weight, the con-

Fig. 2. A sterile arterial homograft as prepared for storage.

centration found to be most effective in sterilizing grafts. The jar is then placed in a water bath at 37°C . for two hours. At thirty minute intervals, the pH of the solution is checked by noting the color of the phenol red indicator. The indicator is orange in an acid media and red in the desired range, (pH of 7.4). Sterile 0.1 molar NaOH is added in sufficient quantities to keep the reaction basic. At times this may require the addition of approximately two to three hundred cc. We add 0.9 cc. of beta-propiolactone for each 100 cc. of the 0.1 molar NaOH added to maintain the one per cent solution of the sterilizing agent during the entire procedure.

At the end of a two-hour period of sterilization, the graft is transferred to a 0.2 molar phosphate buffer-solution (pH 7.4) and rinsed. Either this sterile saline-bicarbonate solution (outlined above) or a balanced salt solution, such as Ringer's solution,* can be used. After rinsing, the graft is placed in either fresh Ringer's solution,* Hank's solution,** or the saline-bicarbonate-phenol red solution (as above) and refrigerated at $1^\circ\text{--}4^\circ\text{C}$. After twenty-four hours, a sample of the fluid and a piece of the graft are taken for culture and

*Abbott Laboratories, North Chicago, Illinois.

1,000,000 units of penicillin and one gram of streptomycin are then added. If the results of the culture are sterile, the graft may safely be used.

Grafts so stored should be used within sixty days.

Fig. 3. An arterial homograft used to replace an aneurysm of the lumbar aorta.

If it is desired to keep them longer, up to a year, they should be preserved by quick freezing. Place the sterilized graft in a sterile empty pyrex tube of suitable size. Seal it with a tight-fitting rubber stopper and cover with sealing wax. Immerse it in a mixture of equal parts dry ice and absolute alcohol (or acetone), with the temperature -72° to -76° C. An "insulated ice bucket" of the home type is an excellent container for this ice-alcohol preparation. One should guard the hands against frost-bite when working with such agents.

While the contents of the sealed tube are freezing, the dry ice-alcohol mixture will "boil" for five to ten minutes. After fifteen minutes the tube can be removed and placed in a standard deep freezer at -10° C. for storage until the time of utilization. In this fashion, grafts may be stored for periods up to one year.

The grafts may be thawed for use by placing the sealed tube in warm water (37° C.) for ten to fifteen minutes and then aseptically removed from the container and placed in 500 cc. of saline with penicillin, streptomycin, and 50 mgm. of heparin. A graft should not be thawed more than once and should be used as soon as possible after thawing.

TABLE I. ARTERIAL HOMOGRAFTS

Femoral vein	Trauma	1		1	
Totals		41	32	2	7

Results

To date, forty-one arterial homografts sterilized in this manner have been placed in patients (Table I). The grafts are uniformly soft and pliable after this kind of preparation and aside from a red stain imparted by the indicator, are difficult to differentiate from a fresh vessel. These patients have been observed from three months to three years. There has been no late rupture in this series and but two late occlusions. In addition, an arterial homograft replacing a common femoral vein which had been destroyed by a gun shot wound functioned for ten days. This was as long as expected and an adequate interval for the development of sufficient collaterals to protect the extremity (Fig. 3).

Discussion

Until further studies in fat metabolism and its transport lead to better prevention for arteriosclerosis, vascular replacements are certain to be required for the more seriously diseased areas. Too, the increasing incidence of automobile accidents in which there is a serious loss of arterial structure creates additional need for suitable vascular substitutes.

The techniques herein presented for homograft sterilization and preservation are both simple and satisfactory. No special and expensive apparatus is necessary. The estimated cost per graft is less than one dollar. Although large homograft banks responsible for service to many hospitals must have a method of easy transportation of sterile grafts over large areas and will continue to utilize the freeze-dry techniques of arterial preservation, the smaller community will find these techniques we have described suitable for their more limited use.

Iatrogenic Atherosclerosis

WINSTON R. MILLER, M.D.
Red Wing, Minnesota

IT IS NOW virtually an accepted fact that high fat diets in large population groups over a period of many years predispose to consistently high serum cholesterol levels and a high incidence of atherosclerosis.¹⁻⁴ The idea of iatrogenic atherosclerosis came by following reports of these recent studies while simultaneously prescribing therapeutic diets for diabetic and ulcer patients. We Americans eat more fat than any other people,¹ and American physicians are prescribing diabetic, ulcer and even some reducing diets which contain more fat than the average population consumes. Furthermore, we have been prescribing these same diets for the past ten to twenty years. The average fat intake of the American people ten to twenty years ago was 10 per cent to 20 per cent less than it is today.¹ Diabetic and ulcer patients as a group have an incidence of atherosclerosis roughly twice that of the general population.^{5,6} Is it not likely that we have contributed to this astounding mortality rate by our diet prescriptions?

There is no question that there are anatomical, hormonal, familial and perhaps racial factors in the pathogenesis of atherosclerosis.⁶ However, the evidence now points toward the concept that these are minor factors, while the major factors lie in fat metabolism.⁷⁻¹⁰ Populations with a high percentage of total caloric intake in the form of fat have high serum cholesterol and a high incidence of atherosclerosis and vice versa.^{4,11,12} The exact roles of the unsaturated fats versus the saturated fats, total serum lipids versus serum cholesterol and total lipoprotein versus Sf 10-20, or Beta lipoproteins, are still controversial.

Patients with diabetes, chronic peptic ulcer, myxedema, nephrosis, lipoid dystrophies, obesity and hypertension have higher incidence of atherosclerosis than the general population. In the last forty-five years the American population has increased its fat consumption from 32 per cent of the total calories to 42 per cent.¹ During this same time the incidence of coronary atherosclerosis has

increased two to three-fold. There is also a definite tendency for atherosclerosis to develop at a younger age.^{1,13} Physicians in general, and internists in particular, therefore have an obligation to prescribe diets which tend to delay the development of atherosclerosis.

An analysis of three general diets as served in one of our hospitals is presented in Table I-a. The percentage of calories derived from fat is above the national average of 42 per cent. Table I-b shows a modification of these three general diets and a special low fat general diet. In the three general diets, fried foods, fatty meats, gravies, cream and cream products, and rich desserts were omitted, and the amount of butter was kept at a minimum. The reduction in fat is modest, but it is reduced to the level consumed in America in 1910 when the incidence of atherosclerosis was much lower than now.

For people to follow a reasonable low fat diet, it is necessary that the diet be palatable and practical. Therefore, with the co-operation of my wife, I attempted to follow the general principles and still live normally. A new recipe book written by the wives of Dr. Eugene Stead and Dr. James Warren entitled "Low Fat Cookery"¹⁴ was used at home. Food eaten at restaurants and dinners away from home was selected within the limits of practicality and good manners. The special general diet shown in Table I-b represents the averages of one week of menus of this diet. The week included

Presented at the meeting of the Minnesota Society of Internal Medicine, Red Wing, Minnesota, May 25, 1957.

#3	115	307	119	2760	39

six lunches and one dinner eaten away from home. Occasionally meals away from home were unavoidably high in fat, but these were balanced by several very low fat meals. I was quite surprised at the degree of reduction, the relative ease of success, and the general acceptability of the diet. This diet represents the result of eliminating all possible sources of fat in a person who wants moderately large servings of meat. It does not contain much added unsaturated fats. Corn oil was used in small amounts only. If one wanted to maintain the same percentage of fat calories and add more unsaturated fats, a reduction in the quantities of meat would be required. Substitution of fish for several meals each week might be done as a compromise.

Table II-a shows an analysis of the commonly prescribed ulcer diets. These are standard ulcer diets used widely in the medical management of peptic ulcer. They employ large amounts of milk, cream and butter. The percentage of calories derived from fat is therefore the highest of any diets analyzed.

Table II-b shows a simple modification of these diets. Half-and-half was changed to whole milk, and butter and other fats were reduced moderately. Since the effect of fats on stomach secretion and motility is a desired response in medical management of peptic ulcer, greater difficulties in management might be anticipated with low fat diets. The presented modifications therefore represent a compromise between the high fat diets usually prescribed and the 20 per cent fat calorie diet considered most desirable to reduce atherosclerosis. These modified diets have been tried on several ulcer patients with good results. Actually, the modified diets are more acceptable to most patients than the high fat diets.

Diabetes is an important disease from the standpoint of dietary prescription and the development of atherosclerosis. Particularly important is the

group of juvenile or young adult diabetics. A great many of the young diabetic patients develop the complications of diabetes before reaching old age. It is certainly the physician's responsibility to do the best possible for these people. Diabetic patients have been treated with high fat diets for many years to avoid carbohydrates as much as possible. Recently, the trend has been toward a more normal type diet with only the elimination of sugar. Actually, it is difficult to see any real reason to forbid all sugar, unless it is because we don't trust our diabetic patients to regulate the amount. Butter on their bread may be more harmful to them than jelly or jam.

Table III shows the composition of twelve diabetic diets.¹⁵ The percentage of calories derived from fat can be seen to equal or slightly exceed the national average. When consideration is given to the fact that almost all persons with diabetes lose part of their ingested carbohydrate in postprandial glycosuria, it becomes apparent that their metabolism is derived even more from fat than these figures indicate.

Table IV shows a modification of American Diabetes Association diets #7, #8 and #9, and a special diabetic diet formulated and tried by the author. The fat exchange (1 tsp. butter, or equivalent) of ADA diets were eliminated and whole milk was changed to skim milk or buttermilk. In the special diet, the same principle was followed, but the patient was allowed three fat exchanges a day. This patient is a thirty-nine-year-old housewife with moderately labile diabetes of two years' duration requiring 25 units of NPH insulin daily. She understood the principle of the diet readily

TABLE V. REDUCING DIETS

	P	C	F	Cal.	% F. Cal.

and considered the diet entirely acceptable. She has been well controlled on this diet for about eight months, except for one episode of acidosis associated with an acute streptococcus pharyngitis. The only adjustment necessary was an increase in the amount of the bedtime lunch.

The only reference found in textbooks on low fat diabetic diets was a statement from the new text by Danowski,¹⁶ which is quoted as follows:

... Evidence is accumulating that the incidence and intensity of atherosclerosis changes in populations as a whole are correlated not only with total calories, but the proportion of fat in the diet. It seems probable therefore that diabetic diets may also have too large an intake of fat. It seems reasonable to try in the next decade or two dietary prescriptions which are lower in fat content and perhaps with the source of fat, i.e., animal versus vegetable, and the type of vegetable fat, specified in the hope of reducing the incidence of nephropathy, retinopathy and arteriosclerosis in the diabetic."

Table V shows the summary of four reducing diets given in a book on therapeutics.¹⁷ Even reducing diets are being prescribed which are high in fat. People who are reducing are necessarily burning depot fat every day in addition to their dietary intake. Therefore, a person on any of these reducing diets actually is metabolizing a considerably higher percentage of his calories from fat than the table indicates. This is not difficult for the physician to change, since many reducing diets follow the general principle of qualitatively eliminating all possible fats and greatly restricting all refined carbohydrates.

Conclusion

The convincing statistical parallelism between high fat diets and high incidence of atherosclerosis suggests a need for reappraisal of diet therapy.

The proportion of total calories derived from fat in three general diets in a local hospital ranged from 43 per cent to 52 per cent. This is compared with the national average of 42 per cent in 1955 and 32 per cent in 1910. The percentage of fat

calories in prescribed ulcer and diabetic diets ranges from 36 per cent to 72 per cent. A group of reducing diets showed a range of 35 per cent to 49 per cent.

The higher incidence of atherosclerosis in diabetic and ulcer patients may be partly iatrogenic because of the high fat diets prescribed.

Suggested modifications are given which reduce the percentage of fat calories in prescribed diets to a range of 18 per cent to 30 per cent.

Acknowledgment

The author wishes to express his appreciation for the assistance given by Miss Esther Leverentz, dietitian at St. John's Hospital, in analyzing the constituents of some of the diets presented.

Trigeminal Neuralgia

One Hundred Fifty Years of Nonsurgical Treatment

JOSEPH G. RUSHTON, M.D.

Rochester, Minnesota

A DETAILED review of medical literature concerning the nonsurgical treatment of trigeminal neuralgia for the past 150 years would be arduous for the author, tedious to the reader and profitable to neither. I have attempted to choose examples of the major fads in treatment, outstanding for their popularity or for their novelty. In most instances only one or two authors are cited. These are usually men who first advocated the method of treatment or who have written papers that are considered to be of more than average interest. The term "nonsurgical treatment" as used herein will exclude measures such as extraction of teeth, operations on the nose and sinuses, injection of noxious substances into the fifth cranial nerve or its branches, and a variety of pullings, stretchings, burnings and cuttings of the nerve. Other measures intended to relieve the pain of trigeminal neuralgia will be included.

It is not proper to enter, here, into the controversy as to who first described trigeminal neuralgia. For practical purposes our present-day knowledge of the condition begins with Fothergill¹ who, in 1776, reported "Of a painful affection of the face." In an attempt to bring relief to his patients he gave them hemlock. This is probably the same drug that was used to bring about the untimely demise of Socrates, but in the hands of Fothergill it was employed in modest doses. At that time it had a reputation for curing cancer and phthisis, and for a while it seemed to relieve the pain of trigeminal neuralgia. After the contribution of Fothergill, interest in trigeminal neuralgia grew and so did the number of remedies. In 1825, Blackett² summarized progress to that date as follows: "In the treatment of this disease physicians

and surgeons . . . have their different theories and modes of treatment; of their inefficacy we have abundant and melancholy proofs." If he were here today he would have little cause to alter his opinion. A few years later, Chapman³ complained, "Even up to the present moment the medical journals teem with fresh contributions to the overgrown and redundant accumulations of remedies."

In 1786 Blunt⁴ reported his experience in treating a painful affection of the face. He recognized the condition to be the same as that described by Fothergill and used the extract of hemlock. By this time the drug had passed its prime and was quite ineffective. "In this distressful situation I recommended to her electricity." The lady accepted this and Blunt goes on to say, "I electrified her twice that day." Used by Chaucer this sentence would have had a much different meaning. Blunt intended to convey the information that he had used electricity to produce sparks and shocks to "the part which had been uniformly the seat of pain." After three days of treatment the patient was relieved and did not suffer recurrence of pain for the next three years, that is, up to the time of the report.

During the nineteenth century, Faraday, D'Arsonval, Hertz and others greatly advanced our knowledge of electricity. Medical uses for some of these advances were discovered. Galvanism,^{5,6} high-frequency current,⁷ diathermy,⁸ and rapid sinusoidal current⁹ were all used with signal success to salve the pain of trigeminal neuralgia. Finally, in 1949,¹⁰ it was discovered that these pains could be dissipated during the course of electroshock therapy given for emotional disorders.

A continued consideration of physical measures used to treat this condition seems appropriate before turning to other methods. Colville,¹¹ in 1814, cured a man by vigorously rubbing tar into the afflicted side of the face. Whether this should be considered a physical measure is, perhaps, open

o doubt, but the massage may be enough to make it qualify. Baird¹² used steam directed, of all places, onto the abdomen of a young lady who suffered from this malady. If you wonder why the abdomen, the explanation is this: *Tic douloureux* was thought in that time to be secondary to some vague but virulent disorder of the digestive organs. It had become known that the sympathetic nerves were arranged up and down the trunk, that they extended into the neck and that they ended intracranially in the region of the fifth cranial nerve. This fragile fact was all that was needed to provide a theory, and was used to justify this and subsequent treatments. Winteritz¹³ and Walker¹⁴ applied ice to the face of the victim as often and as long as he could bear it. By this means they were able to "cure" patients in whom "all other methods of treatment had failed." A gentleman by the name of Neale¹⁵ reported on the use of an instrument which he called a "vibrator." His description suggests that it was somewhat like a Lilliputian jackhammer. The instrument was applied over the painful regions of the face. He was of the opinion that by pummeling, he could palliate the prosopalgia of any poor wretch who came his way.

More strictly medicinal measures also were used in the early treatment of trigeminal neuralgia. Pearson¹⁶ used mercury with heroic vigor. The patient took it by mouth as calomel and it was rubbed into the skin in the form of mercury ointment. Treatment was continued until it produced stomatitis and gingivitis just short of spontaneous shedding of the teeth. One lady, quoted by Pearson, stated of her pain, "There was no lasting relief till the sore mouth and the spitting came on." This same author noted that some patients complained more of the evil effects of the treatment than of the pain caused by *tic douloureux*. McKechnie¹⁷ used arsenic solution in a wonderful and fearful manner. The drug was given in increasing doses until "sensible signs of the operation of the medicine would be observed." This was a gentle way of saying that the patient was poisoned with arsenic. Next came "the bark,"¹⁸ that is, quinine, which was used because the pain was thought to be rheumatic. Whatever the reason, quinine seemed effective for a time. The use of iron carbonate became common about 1820. It was given in large doses—up to 8 ounces in thirty-six hours²—to the point that it produced constipation, diarrhea, or sore mouth. Beale¹⁹ wrote, "This is

one of the most fortunate discoveries, in curing a disease formidable alike from its obstinacy and its violence." The heyday of this drug lasted about fifteen years, but its use was revived as late as 1949 by Davidoff and Feiring.²⁰

Translation into English of a paper by Magendie²¹ awakened interest in the use of hydrocyanic acid as a medicinal agent (1818). As late as 1838 its use was hotly defended by Hall.²² Taylor²³ used a dilute solution of this violent poison to relieve the pain of trigeminal neuralgia. His report includes observations on patients for as long as three and one-half years after pain was stopped. One wishes that some present-day medical scientists would be as patient in reporting their results. Loudon²⁴ advised the application of an emplastrum of laurel leaves to the face. He found this poetic sounding remedy to be extremely efficacious. Laurel leaf was known to be poisonous if taken internally owing, in part, to its content of hydrocyanic acid.

In the 1820's accounts of cures by means of purgatives began to appear in the literature. Their use was predicated on the afore-mentioned theory, and the preparations included awesome mixtures of calomel, croton oil, and antimony tartrate. One author²⁵ mentioned that, when his patient had recovered from the treatment sufficiently to walk, he left the hospital completely cured of his pain. One is impressed by the frequent use of the word "cure" to describe the outcome of treatment for this condition. Evidence for cure often took the form of a statement that the patient failed to return to the physician and therefore cure might be assumed. Other explanations for the patient's failure to return will occur to the reader. A late reference to the use of purgatives for this condition is that of Gill²⁶ in 1905. He gave one ounce of castor oil daily for fourteen days. When I think of how present-day patients complain of taking a single dose of castor oil I reflect, "There were giants in the earth in those days," and our patients seem a pallid lot by comparison. Chapman³ advocated "puking" as the best treatment. It failed to become popular.

In Boston, in 1846, Morton demonstrated the anesthetic properties of ether. Sibson²⁷ was a fellow who kept posted on such matters, and in 1847 he published a modest article in which he claimed that the inhalation of ether was useful "as a means of cutting short the paroxysms . . . and of rendering the system amenable to a scientific treatment."

He did not elaborate on what this scientific treatment might be.

Trousseau²⁸ coined the term "epileptiform neuralgia" for trigeminal neuralgia because of its fancied resemblance to an epileptiform seizure. He was of the opinion that surgical operations for the relief of this pain were risky business and that all medical measures had been ineffective. For these reasons, he proposed the use of large amounts of opiate. One of his patients was given "15 à 20 centigrammes" of morphine sulfate per day (2.25 to 3.0 grains). This dose was gradually increased so that after the fifteenth day the patient took "jusqu'à 4 grammes de sulfate de morphine" each day (60 grains). Trousseau commented that these huge doses did not affect the patient's digestion or mentality, but the cost of the drug was ruinous. In order to avoid financial calamity, the patient purchased crude opium in kilogram lots and from this made "bols de 1 gramme." She would take ten to twenty of these each day as needed. The author went on to mention that the patient would have remissions of two or three months during which she would use no opium at all.

A strange name appeared in the long list of drugs used to treat trigeminal neuralgia when, in 1872, Legg²⁹ reported the successful use of croton chloral. This was a by-product of the manufacture of chloral hydrate and was thought to have the peculiar property of producing anesthesia of the head. It was later proved to be butylchloral hydrate with properties similar to those of chloral hydrate. With this damaging revelation its popularity waned. Thompson³⁰ used phosphorus and reported on its effects in twelve patients, a large number for those days. He admitted that it had a foul taste, but he was able to disguise it with spirits of peppermint so that his patients could be induced to take it. One of his patients enjoyed a "cure," ten "recovered," and one did not obtain any beneficial effect. This will compare favorably with many reports of today.

Beginning in 1874,^{31,32} there was a flurry of excitement over the use of *Gelsemium sempervirens* in the cure of trigeminal neuralgia. It was given in the form of a tincture which was thought to impair the sensibility of sensory nerves. If taken in large enough amounts it would produce giddiness or even unconsciousness. Nitrite of amyl was found by Evans³³ to be effective. His patients sniffed it to the point of giddiness or unconsciousness and were quite pleased with the results. Its

beneficial effects were still being reported as late as 1941.³⁴ Another vasodilator, nitroglycerin, was mentioned favorably in 1885 by Deahofe.³⁵

The writings of Trousseau caused Peter³⁶ to conclude that epileptiform neuralgia should be treated as epilepsy. He gave potassium bromide in doses of 6 gm. per day to accomplish this and his efforts were crowned with success. From 1878³⁷ to 1902³⁸ aconite was held in high esteem. The use of so-called heroic doses of strychnine was urged by Dana.³⁹ The treatment started with a dose of 1/30 grain each day and gradually increased to 1/4 grain each day. In addition he used eliminants, such as potassium iodide, and a tonic in the form of tincture of iron, plus rest in bed, light diet and diluents. This total "push" program may have kept the patients too busy to notice the pain.

The subject of endocrinology was not neglected. French⁴⁰ argued that persons with hypothyroidism may have many odd pains and those of trigeminal neuralgia might be included. He tested and proved this theory by relieving these pains with thyroid extract. Tracy⁴¹ reported the case of a man who complained of lacrimation and "much mucus in the mouth" during his bouts of pain. With this clue he was able to free his patient of pain by giving him pilocarpine until it produced dryness of the mouth.

The 1920's were relatively arid. In 1930 Ball⁴² was successful in alleviating pain owing to tic douloureux by means of artificial fever resulting from the injection of boiled milk. Later^{43,44} intravenous injections of typhoid vaccine were used for the same purpose and with the same good results. In view of the beneficial effects of vasodilators, such as amyl nitrite and nitroglycerin, it is a surprise to learn that Tyler⁴⁵ and Dichter⁴⁶ obtained equally good results with the vasoconstrictor ergotamine tartrate. Charlin⁴⁷ assumed that in some cases trigeminal neuralgia was related in some way to tuberculous toxemia; he was able to dispel the pains of these patients by injections of old tuberculin.

In 1940, the vitamin era was ushered in by Borsook and his associates.⁴⁸ They argued that the effectiveness of vitamin B₁ in relieving the pains of polyneuritis of alcohol and pregnancy might well carry over to the pain of tic douloureux. Their method consisted of injections of large doses of thiamine chloride and modification of the diet with nutritional supplements. There were no

"cures" but their patients, for the most part, were markedly improved or improved. Twelve years later a similar success was enjoyed with vitamin B₁₂.⁴⁹

The year 1948 was a good one for sufferers from tic pain. Bee venom,⁵⁰ dietary control,⁵¹ cupreone,⁵² and antihistamines⁵³ were added to the long list. Later, Stich⁵⁴ assumed that banthine inhibited the gasserian ganglion in the same manner as it did the autonomic ganglia. As evidence, he reported the case of a man who was able to control his pain by taking the drug every six or seven hours. The tranquilizers will not only ease mental anguish but they are reported to have a calming action on the pains caused by trigeminal neuralgia.⁵⁵

Finally, let us consider two drugs which are unusual in that their use was founded on astute observation and reasonably good logic. The first of these is trichloroethylene. This was used as a solvent in Germany during World War I. In 1915 Plessner⁵⁶ reported that one of the toxic effects of this substance was the production of neuritis of the sensory portion of the fifth nerve. A year later he reported that the use of this drug had relieved the pain of twelve of fourteen patients having trigeminal neuralgia. Glaser⁵⁷ reviewed the literature concerning this treatment in 1931 and found the proportion of patients benefited to be much smaller. Stilbamidine has been used in the treatment of certain tropical diseases for many years. One of its toxic effects is the production of sensory neuritis, usually limited to the head and neck. This property suggested its use for the treatment of trigeminal neuralgia. Smith and Miller⁵⁸ reported glowingly concerning its capacity to relieve pain caused by tic douloureux. Unfortunately, the neuritis which it produces may be associated with painful paresthesia as bad as or worse than the original pain.

That no regularly effective, nonsurgical treatment for trigeminal neuralgia has yet been proposed is the only conclusion to be derived from the information presented herein. This might suggest a second conclusion; that is, that no form of nonsurgical treatment should be used. I do not agree with this. Often a patient is seen at a time when his present attack gives promise of subsiding. Another patient may decline a surgical operation. A third, having sufficient pain to justify an operation under ordinary circumstances, may have some other illness which increases the risk of operation

so greatly that it must be avoided if possible. In each case, the patient expects and deserves that some effort be exerted to make him more comfortable. From this long list of remedies may be chosen one which suits the temperament of patient and physician and at the same time is relatively free from undesirable side effects. Its use may coincide with lessening of the pain and the patient will be gratified. A final lesson may be gleaned. Each of these remedies, with the possible exception of those which have come into use most recently, has enjoyed a measure of favor and fame only to slip into quiet oblivion. This suggests that any new nonsurgical measure for the relief of trigeminal neuralgia should be accepted with tolerant skepticism until sufficient time has passed to allow for mature consideration of its benefits and limitations.

COLOR BLINDNESS

Some false notions about color blindness have been corrected by Commander Dean Farnsworth of the U. S. Naval Medical Research Laboratory, New London, Connecticut. Ten per cent of American men, but only one per cent of the women are color blind; it is inherited, usually from a man's maternal grandfather; it is not

curable nor can it be remedied; it cannot be acquired by alcohol, tobacco, sickness or any other means; color-blind persons, with a few rare exceptions, are not insensitive to all color.—17th Annual *Congress on Industrial Health*, Los Angeles, Feb. 4-6, 1957.

Primary Malignancies of the Lung

Advances in Diagnosis and Treatment

JOHN W. BRAASCH, M.D.
Minneapolis, Minnesota

IN THE LAST decade there has been great interest in the problem of carcinoma of the lung. This interest has been stimulated by an increasing awareness of the great strides that have been made in thoracic surgery during this time and the relative prevalence of this disease which now approximates carcinoma of the stomach in frequency among men. No longer does thoracotomy mean that the patient's cemetery lot should

TABLE I. CLINICAL CHARACTERISTICS OF THE MICROSCOPIC TYPES OF CARCINOMA OF THE LUNG

Cell Type	Number	Percent	Ratio Males : Females	Location

be readied. Instead, there has been an increasing realization that an exploratory procedure carries only a slightly more increased risk than laparotomy. Accordingly, a more aggressive approach to the problem of carcinoma of the lung is feasible. Coupled with this lowering of surgical risk have been advances in the diagnosis and basic understanding of this disease. Careful evaluation of the results that these changes in perspective have produced is now possible and, indeed, necessary to plot further the course which should be followed in the management of this disease. In the following paragraphs I shall review some of the important advances which have been made and evaluate them in the light of future progress to be made in treating these tumors.

One of the greatest advances in recent years in the diagnosis and treatment of carcinoma of the

lung has been the recognition of the implication of the microscopic classification of these tumors. It has been emphasized by Moersch and McDonald¹ that there are four main types of lung carcinomas—the squamous cell, large cell, small cell and adenocarcinoma. Table I summarizes the clinical characteristics of these groups as to relative prevalence, sex incidence and location in the tracheobronchial tree. In a series of 1000

TABLE II. OPERABILITY, RESECTABILITY AND SURVIVAL IN VARIOUS MICROSCOPIC TYPES OF CARCINOMA OF THE LUNG

Cell Type	Number	Percent Explored	Percent Resected*	Two Year Survival	
				Percent of Resected	Percent of Total

** Calculated value

cases the two-year survival rate of patients with the various types of lesions is shown in Table II. The differences shown in the characteristics and behavior of these groups justifies this classification. It is apparent from these data that the prognosis for patients with squamous cell carcinoma who have undergone curative pulmonary resection is relatively good, but, on the other hand, the prognosis of individuals with small cell tumors is almost invariably bad. This fact is of extreme importance, in that we must not allow our approach to this problem to be colored by the results in unfavorable types of lesions. Further augmenting the obvious usefulness of the typing of the lesion by microscopic means, is the proven ability of the experienced pathologist to ascertain the histologic type of the lesion from an examination of suitably prepared sputa or bronchial washings. The decision for or against thoracotomy or the choice among the various resective procedures

From the Departments of Surgery, General, Northwestern, Abbott, and St. Barnabas Hospitals, Minneapolis, Minnesota.

is influenced greatly by what the pathologist can tell us preoperatively.

Another advance of diagnostic importance has been the demonstration by Daniels² of the usefulness of prescalene node exploration and biopsy. Rouviere³ has demonstrated that these easily accessible nodes which lie just lateral to the clavicular attachment of the sternocleidomastoid muscle are way-stations in the pathway of lymphogenous spread of carcinoma of the lung to the great veins. Harken et al⁴ have shown that even without clinically palpable lymph nodes in this region, biopsy of the prescalene nodes frequently shows carcinomatous involvement. These workers have enlarged the scope of the biopsy procedure to include the upper mediastinum, using laryngoscopic visualization through the incision, but Connor⁵ maintains that the paratracheal biopsy is not necessary for satisfactory results from this procedure. A positive biopsy procedure gives positive information that the tumor has spread beyond the area of the usual surgical procedure and, of course, also allows a prethoracotomy microscopic diagnosis to be made. Involvement of these nodes limits any surgical attempts to palliative procedures which usually would not be indicated in the case of small cell carcinoma and would be limited to those cases where infection or hemorrhage was a problem.

Certain techniques of the pulmonary physiologist have been applied to the patient with carcinoma of the lung in an effort to avoid the postoperative problem of respiratory and cardiorespiratory failure. The thoracic surgeon who deals with pulmonary tuberculosis is aware of the problems encountered postoperatively from respiratory failure following excisional or collapse therapy. As has been pointed out by Woodruff et al,⁶ Gaensler et al⁷ and others, inadequate performance preoperatively of the maximal breathing capacity test heralds respiratory trouble postoperatively. In dealing with patients with carcinoma of the lung, this problem is usually not so acute but it is present. Certainly, any patient who shows evidence of the presence of specific or nonspecific fibrosis, old inflammation or emphysema in the contralateral lung should have an adequate preoperative evaluation of pulmonary function, using some of these carefully developed tests. Certainly attention should be given also to the capacity of the patient for physical exercise in evaluating pulmonary function.

The development of certain technical procedures in the last few years has allowed an extension of the scope of resective therapy. Mediastinal lymph node dissection en bloc with the tumor (Brock⁸, Watson,⁹ Gibbon et al,¹⁰ and Boyd et al¹¹) has been and is being done by some thoracic surgeons. The reported operative mortality rates following the use of these techniques are variable. It is too early to tell if this procedure is followed by a higher survival rate, and if this increased survival is not offset by increases in postoperative morbidity and mortality following possible interference with the blood supply of the bronchial stump. It is not unreasonable to suppose, however, that if applied to the squamous cell group of tumors it might increase the longevity of the patients so afflicted.

Resection of the carina and main stem bronchus (Paulson and Shaw¹²) has been accomplished with anastomosis of the distal bronchial stump to the proximal trachea. Portions of the trachea and bronchi have been excised with closure by certain plastic procedures using skin grafts (Gebauer,¹³ and Abbott et al¹⁴). These procedures are more applicable to the treatment of a certain less malignant group of lesions, the bronchial adenomas, or to save functioning lung tissue in patients with carcinoma who have limited respiratory reserves.

The controversy over the choice of pneumonectomy or lobectomy for malignancies of the lung still rages. Certainly there is justification for the more limited procedure in patients with reduced pulmonary reserves. As in the case of evaluating the more radical types of pneumonectomy, with the information available today, no definite decision can be made regarding the merits of lobectomy or pneumonectomy in carcinoma not involving or close to the main stem bronchus.

Progress has been made in clarifying the group of tumors known as bronchial adenomas. That these tumors do metastasize has been recognized. Soutter et al¹⁵ and McBurney et al¹⁶ have shown that of the two types of adenomas, the cylindroma and the carcinoid, the former is more prone to embolic spread. Certainly, these tumors merit removal. At times, a limited resection of the bronchus involved is possible; however, the frequently occurring obstructive pneumonitis and cavitation distal to these tumors often makes lobectomy or pneumonectomy mandatory. As was mentioned earlier, resection of the carina is now possible, and this is now preferable in some cases

to the endoscopic treatment of these previously inoperable carinal lesions.

Additional cases of pulmonary adenomatosis or alveolar-cell carcinoma have been reported, and the older cases have been summarized by Storey et al.¹⁷ Contrary to previous opinions, these authors feel that these tumors are not multicentric in origin, that in early cases they are not characterized by a bronchorrhea of glairy sputa and that, given adequate treatment, the prognosis for cure is as good or better than the ordinary carcinoma of the lung. Certainly, any one thoracic surgeon's experience with this tumor is not extensive enough to solve these points conclusively.

Improvement in the general outlook for the patient with carcinoma of the lung must of necessity come from three avenues of approach. These are either earlier diagnosis, more radical surgical treatment or the development of some new type of therapy. Appropriate to this discussion is an inquiry into the fate of those cases of carcinoma of the lung which were discovered by the routine chest x-ray. McNulty¹⁸ reported on the results obtained with the surgical treatment of thirty-nine cases of bronchogenic carcinoma discovered on a chest x-ray survey. Approximately two-thirds were resectable, but this improvement in resectability was not reflected in the overall three-year survival data of approximately 10 per cent. Conversely, Overholt et al.¹⁹ found a 30 per cent three-year survival in a group of thirty patients with bronchogenic carcinoma who were asymptomatic and whose cases were discovered on routine chest survey. Presumably the lack of symptoms in the patients of the latter group attests to their being earlier cases. For purposes of comparison, the two to five-year survival following surgical treatment of symptomatic lesions is approximately 10 to 15 per cent. Unfortunately, the information gained from these two reports is inadequate and no definite conclusions can be reached. It would be helpful to have a larger series of cases with information as to the histologic type of lesion.

Just what the newer, more radical surgical techniques have to offer remains to be determined. Perhaps in the case of the squamous cell tumors these procedures might be valuable. I suspect, however, that they will not better the results obtained with the other types of tumors.

There are no new therapeutic methods on the horizon. Radiation therapy (Mayer and Rosurt²⁰) occasionally is followed by a long term survival.

The newer techniques using radio-cobalt or high energy beta radiation are an improvement over the usual roentgen therapy, but probably will not change the overall picture appreciably.

It is hoped that the years ahead will bring answers to the questions centering on the extent of the operative procedure which should be used. Further experience with the treatment of the asymptomatic carcinoma should be recorded which would predict the usefulness of chest x-ray screening in selected population segments. The intimate association of this problem with the homotransplantation problem is readily apparent. Our attempts at radical surgery are severely limited by the necessity of preserving structures so close to the primary tumor. And, finally, we must recognize the association of the lung cancer problem with that of other neoplasias and look with hope on continuing fruitful work in these fields. Certainly, as this work is progressing we must not lose sight of the fact that the results following resections with the hope of cure in the squamous cell group of tumors are not as bad as with many other malignancies, there being a two to five-year survival of about 40 per cent.

Three-Year Study of Neonatal Deaths in Hennepin County

BY THE HENNEPIN COUNTY
PERINATAL MORTALITY COMMITTEE

THE HENNEPIN County Neonatal Mortality Study* is an analysis of all deaths occurring in Hennepin County in infants of more than twenty weeks' gestation, who die within the first twenty-eight days of life. The study began January 1, 1952. It is a co-operative undertaking sponsored by the Hennepin County Medical Society, Minneapolis Pediatric Society, Minneapolis Obstetric Society, Minneapolis Chapter of the Academy of General Practice, Minneapolis Health Department, Minneapolis Hospital Council, Departments of Pediatrics and Pathology of the University of Minnesota Medical School, and the Minnesota Department of Health. The committee working on the study is composed of representatives from all these groups; members include obstetricians, pediatricians, pathologists, anesthesiologists, general practitioners, radiologists, public health physicians and hospital administrators. Information has been gained by the committee through conferences with hospital personnel on hospital prenatal care, the obstetric course, and infant evaluation, and from statistical data and forms furnished by the hospitals. These data have been transferred to punch cards for ease in tabulation. Analysis by the committee was entirely by code. Since no knowledge of the names of the patient, physician or hospital was given to the committee, each case could be discussed anonymously and impartially. Reports have appeared for 1952¹ and 1953.² Because the 1954 tables are very similar to the data presented for the two previous years of the study, a separate report will not be published. The 1954 data will be found in the Appendix (Tables A-J).

This paper is concerned with the total group of neonatal deaths of infants born in Hennepin County during the years 1952, 1953, and 1954. This study involves 1,012 infants, including thirty-

one sets of twins and one set of triplets, born to 988 mothers.

Types of Delivery

Almost 25 per cent of the deaths noted in this study occurred in infants whose mothers experienced breech deliveries. This is approximately four times the incidence of breech deliveries in normal newborns. Of the infants dying following breech delivery, 85 per cent were born prematurely (Table I).

TABLE I. TYPES OF DELIVERY
Mortality Study, 1952-1954

Type of Delivery	2500 Gms. and Under	Over 2500 Gms.	Total	Per Cent
Cephalic	416	219	635	62.7
Breech	214	36	250	24.7
Version and extraction	6	7	13	1.3
Cesarean section	73	20	93	9.2
Unknown	14	7	21	2.1
Total	723	289	1,012	100.0

Nine per cent of the deaths noted in this study occurred in infants whose mothers gave birth by cesarean section. Of these infants, 78 per cent were born prematurely. It is the opinion of the Hennepin County Perinatal Mortality Committee that flat plate abdominal x-rays should be taken in all cases before an elective or repeat cesarean section is performed, in order to determine whether or not the fetus' proximal tibial or distal femoral epiphyses have formed. These are usually observable by the fetal age of thirty-six weeks. By using abdominal x-rays as a guide for fetal maturity, prematurity, resulting from cesarean sections undertaken too early, can be reduced.

Duration of Life

Almost half of the deaths in this study occurred between one and twenty-four hours after birth. Approximately 75 per cent of the neonatal deaths occurred within the first two days. It is also

*Since 1955 the study has included fetal deaths and is now known as the Hennepin County Perinatal Mortality Study.

NEONATAL DEATHS IN HENNEPIN COUNTY

TABLE II. DURATION OF LIFE
Mortality Study, 1952-1954

Duration of Life	2500 Gms. and Under	Over 2500 Gms.	Total	Per Cent
Under 1 hour	97	32	129	12.8
1 to 24 hours	381	95	476	47.0
25 to 48 hours	120	53	173	17.1
49 to 28 days	125	109	234	23.1
Total	723	289	1,012	100.0

noted that only 125 out of 723 premature infants, or 17 per cent, died between two and twenty-eight days. Of full-term infants, 109 out of 289, or 38 per cent, died between two and twenty-eight days.

Causes of Death

The Committee has conscientiously attempted to determine the primary cause of death in each infant. Abnormal pulmonary ventilation, which accounted for nearly 60 per cent of the deaths noted in this study, included immaturity unqualified, atelectasis, and hyaline membrane disease. It is of interest that prematurity was associated with 90 per cent of the abnormal pulmonary ventilation deaths in this study (Table III).

Congenital anomalies accounted for 17.6 per cent of the deaths noted in this study. During 1952, 1953, and 1954, 17.4 per cent of the neonatal deaths that occurred throughout Minnesota were due to congenital anomalies. Congenital anomalies are, in contrast to abnormal pulmonary ventilation, more frequent in full-term infants. In this study, 37 per cent of the congenital anomaly deaths were found to occur in premature infants. Comparing causes of death for premature with cause of death for full-term infants, congenital malformations accounted for 9 per cent of the deaths of premature infants and 39 per cent of the deaths of full-term infants. Although many congenital anomalies cannot, at the present time, be adequately corrected, early diagnosis of the newborn will reveal some congenital anomalies amenable to medical and surgical care. For example, if the newborn is observed to have frothy mucus forming at the lips and severe coughing following the first feeding, a presumptive diagnosis of esophageal atresia and tracheo-esophageal fistula may be suspected. All newborn infants should be carefully observed for congenital anomalies which may interfere with the vital processes of respiration, swallowing, and elimination of stools and urine. Almost all normal newborn infants

TABLE III. CAUSES OF DEATH
Mortality Study, 1952-1954

Cause of Death	2500 Gms. and Under	Over 2500 Gms.	Total	Per Cent
Abnormal pulmonary ventilation	538	60	598	59.1
Congenital anomalies	66	112	178	17.6
Infection	30	28	58	5.7
Birth trauma	35	23	58	5.7
Blood dyscrasia	14	39	53	5.2
Anoxia	20	11	31	3.1
Others	20	16	36	3.6
Total	723	289	1,012	100.0

pass urine and stools within the first twenty-four hours;³ failure to do so may indicate obstruction.

Infection accounted for 5.7 per cent of the deaths noted in this study. This indicates that more adequate care of the infant is needed. It is the opinion of the Hennepin County Neonatal Mortality Committee that antibiotics should be given to all infants whose mothers have ruptured membranes twenty-four hours before delivery.

In addition to routine examination on all newborns, any infant, who, in the newborn period seems to be listless, takes feedings poorly and has attacks of cyanosis, should have a thorough work-up to exclude possible infection, birth trauma, or congenital anomaly. Congenital anomalies should be suspected and may coexist with an infection. Earlier detection and more adequate care of the newborn infant who is found to have an infection must be undertaken by all physicians responsible for obstetric and newborn care.

Birth trauma accounted for 5.7 per cent of the neonatal deaths reported in this study. It accounted for 8 per cent of the deaths of full-term infants and 4 per cent of the deaths of the premature infants. According to the Minnesota Maternal Mortality Committee,⁴ proper obstetric care should include adequate clinical pelvimetry, particularly of the anteroposterior diameter of the inlet (internal) and intertuberous diameter, plus a necessary knowledge of pelvic architecture. Mid-forceps may be associated with birth trauma. There is no indication for high-forceps. In general, no infant should be delivered through an incompletely dilated cervix.

Blood dyscrasia accounted for 5.2 per cent of the neonatal deaths reported in this study. These deaths were all attributable to erythroblastosis fetalis, except for one death from congenital leukemia. Almost 2 per cent of the deaths of

5. Intercurrent disease	6	9	15	1.5
6. Unavoidable disaster	669	217	886	87.5

the prematures was due to erythroblastosis. The Minnesota Maternal Mortality Committee recommends that all mothers have Rh typing early in pregnancy. If the mother is Rh negative, an Rh test should be done on the father. It is the opinion of the committee that all infants born to Rh negative mothers and Rh positive fathers should at least have an Rh and Coombs test done on the cord blood at birth. If the Coombs test is positive, or if jaundice appears within the first twenty-four hours after birth, the infant has erythroblastosis and should have an early pediatric consultation so that definitive therapy can be given.

Anoxia accounted for 3.1 per cent of the neonatal deaths reported in this study. The Study Committee recommends that fetal heart rates be recorded regularly throughout labor. Too often fetal heart tones are not recorded on the chart. Any marked change in the fetal heart rate may indicate fetal distress, such as a prolapsed cord.

Miscellaneous conditions accounted for 3.6 per cent neonatal deaths noted in this study. The mis-

cellaneous conditions found through this study included tetany of the newborn, ascites of unknown cause, and various undetermined causes of death of some full-term infants.

Autopsies

There has been a continuous increase in the number of autopsies performed. (Table IV). During the three-year study, 54.8 per cent of the prematurely born infants who died were autopsied, 84.4 per cent of the full-term infants who died had autopsies. For all neonatal deaths the average autopsied was 63.2 per cent.

Rating on Neonatal Deaths

Preventable factors were found in forty-four obstetric, ten obstetric-pediatric, nineteen pediatric, and one hospital death during the three-year study. Thus, seventy-four out of 1,012 neonatal deaths, or 7.3 per cent were judged by the Committee to have preventable factors. (Table V). However, improvement in care (numbers 1-5) may have been possible in an additional 17 per cent of the deaths.

Examples of deaths with preventable factors are:

Case 1.—At forty weeks of gestation, the mother entered the hospital in labor. The total length of labor is not known. The fetal presentation was frank breech. Fetal heart tones were not recorded during labor or delivery. A soap-suds enema was done on admission of the mother. One and one-half hours following admission, the membranes were artificially ruptured. Delivery began five minutes following rupture of the membranes along with a 1 per cent novocaine pudendal block. Nitrous oxide-oxygen and cyclopropane were administered during the delivery. A left lateral episiotomy was performed. The infant seemed to make normal progress, and the shoulders were delivered twelve minutes following the onset of delivery. The pelvis then seemed too small for the infant's head to go through. Pressure on the mother's abdomen had no effect. The physician who had been caring for the mother during the entire pregnancy then applied Piper forceps to the head in a transverse application. On traction, the forceps slipped

off and had to be reapplied. Delivery of the head was accomplished eight minutes following delivery of the shoulders, twenty minutes following onset of delivery. The total blood loss was 200 to 300 cc. and the mother was given 500 cc. of blood.

The infant weighed nine pounds, two ounces. Bruises were noted over the infant's left eye and on the side of the head in front of the ear. Tracheal aspiration was performed, with removal of much fluid. The infant did not breathe at any time. Mouth-to-mouth resuscitation was performed, and the infant was then transferred to an Air-lock. At thirty-five minutes of age, the infant's heart beat ceased, and the baby was pronounced dead. Autopsy examination was normal, except for the head. There was a subperiosteal hematoma present over the entire cranial vault, especially on the right side. The scalp itself showed considerable discoloration, the temporal bones showed fractures on both sides. The fractures extended from the anterior margin to about the center of the bone on the left side, and from the posterior margin to involve about two thirds of the width of the bone on the right side. On both sides, the fractures extended through the full thickness of the bone. The dura did not seem to be torn. The cerebrospinal fluid was bloody over the entire surface of the brain. There was a laceration of the falx just posterior to the central portion, and, in addition, there was a complete tear of the left half of the tentorium and about half of the right tentorium. The interior of the brain and the ventricles showed no evidence of hemorrhage and there was no necrosis or other gross change.

Committee comment.—It is generally agreed that any breech presentation should be carefully observed and managed because of increased fetal mortality and trauma to maternal tissues. This is especially true in frank breech cases with suspected large babies, and in elderly primiparas. Prenatal care should be of such a nature to make one aware of potential disproportion between the passenger and the passage. X-ray pelvimetry should be done in all suspected cases before onset of labor. X-ray will also show if the head is flexed or extended. Consultation is advisable. Indicated cesarean section should be elective. Preservation of membranes is advisable. Early and frequent rectal examinations, frequent auscultation and abdominal palpation must be done to evaluate properly the progress of labor. Vaginal examination is frequently advisable after rupture of membranes. Breech should usually be allowed to dilate both cervix and vagina, and labor should be permitted to continue until the umbilicus is delivered, if no difficulty is encountered. Hasty and careless traumatic use of forceps on the after-coming head is ill-advised.

Case 2.—A seventeen-year-old primipara had had some bleeding, amount not known. She was admitted to the hospital at thirty-seven weeks of pregnancy. Hemoglobin on admission was 71 per cent, and she was given two blood transfusions on the day of admission. No consultation was obtained. On the day following admission, she had a cesarean section (nitrous oxide-oxygen anesthesia) because of suspected placenta previa. The infant weighed 4 pounds, 6 ounces, was pink at delivery, and cried in one minute, but then developed cyanosis and was given oxygen. A portable chest x-ray was interpreted as revealing neonatal atelectasis. The respirations became more labored, the feet became edematous, the color remained cyanotic in oxygen, and the infant expired at twenty-six hours of age. An autopsy was not performed, and the cause of death was listed as prematurity.

Committee comment.—In this case, the record was inadequate. No consultation was obtained. Placentogram often aids in the diagnosis of placenta previa. Frequently an expectant hospital management with sensible precaution does not compromise the mother's safety. In the interest of the fetus and avoidance of fetal wastage, the best possible procedure is further prolonging gestation whenever possible.

Case 3.—A twenty-six-year-old mother (four previous full-term infants) had diarrhea and fever for one week prior to delivery. Her first prenatal visit was eight days before delivery. The fetal age was thirty-six weeks, presentation of infant vertex. After seven hours of first stage labor, second stage twenty minutes, she had spontaneous delivery by her obstetrician of an infant weighing 5 pounds and 11 ounces. No anesthesia was used. The mother had 600,000 units of penicillin on the day of delivery. On the day after delivery, the mother's temperature rose suddenly to 103°. A urinalysis and urine culture were both negative. No stool cultures were done, and the diarrhea ceased following delivery. The mother was given aureomycin daily, starting on the day after delivery, and she was afebrile and clinically well on the fifth day when she was discharged with her infant.

At birth, the infant breathed well and a physical examination by a physician was normal. The infant's temperature was 97 to 99° throughout the hospital stay. At two days of age, the infant's hemoglobin was 18.5 grams per cent. No other laboratory tests or cultures were done on the infant. At five days of age, the infant was discharged on an evaporated milk formula, having gained 80 grams over the birth weight of 2600 grams.

At seven days of age, the infant began having loose yellow stools and vomited once. At eleven days of age, because of continued diarrhea, the infant was seen by the physician, who discovered that the mother had not been boiling the water. Physical examination disclosed severe excoriation of the buttocks. No stool examination or culture or other laboratory test was done. The infant was put on half skimmed milk (boiled), but diarrhea

and vomiting continued. On the fourteenth and fifteenth day of life, the infant was again seen by the physician because of watery stools. No cultures or other laboratory work was done. The infant was continued on half skimmed milk (boiled).

On the sixteenth day of life, the infant was readmitted to the hospital because of watery stools and vomiting which had become projectile. The temperature on admission was 98.4°. The infant, who weighed 2164 grams, was cyanotic and dehydrated. Laboratory work on admission revealed a blood chloride content of 117 milliequivalents per liter, blood carbon dioxide content of 8 milli-equivalents per liter, hemoglobin of 19 grams per cent. A throat culture revealed *E. coli*, but a blood culture was sterile. The infant was put in an incubator and started on 200 cc. intravenously of a hydrating solution (one third normal saline and two thirds 5 per cent glucose in water, with an added 12 cc. of 1 molar lactate solution). 200,000 units of penicillin and 25 milligrams of streptomycin were also given intramuscularly. Dark brown material began to drain from the infant's nose, and the infant expired ten and one half hours following admission, at the age of seventeen days. At autopsy, cerebrospinal fluid culture revealed the presence of *E. coli*; stool culture revealed no salmonella or shigella. Autopsy examination revealed the trachea and bronchi to be filled with a light pink frothy material. The lungs were markedly edematous on cut surface. The gastrointestinal tract appeared grossly normal. On microscopic examination, the mucosa of the small intestine was grossly infiltrated with leukocytes, macrophages, and fibroblasts. There was a superficial mucosal ulceration in one area. The lungs on microscopic examination showed the presence of pulmonary edema.

Committee comment.—An infant in the first month of life who has continuous loose stools is apt to have both dehydration and electrolyte imbalance. It is very essential that early intravenous, and not subcutaneous, administration of electrolytes be given. These children in some instances may lose an average of 8 ounces per day which represents far more than just the loss of fluids. The loss of essential electrolytes which should be replaced in the circulation necessitates prompt intravenous therapy.

Case 4.—A thirty-six-year-old mother (four full-term living infants) had a normal pregnancy. Labor began at thirty-nine weeks of pregnancy, and delivery was spontaneous under no anesthesia. The amniotic fluid was stained yellow and the placenta was edematous. The infant weighed five pounds and ten ounces. The child was cyanotic from birth and had a high pitched cry. The respirations were irregular. The physician taking care of the infant found hepatosplenomegaly. Laboratory tests done on the infant at seven hours of age revealed the following: hemoglobin 8.4 grams per cent, red blood cell count 1,950,000 per cubic milliliter, white blood cell count 21,360 per cubic milliliter, normoblast count

70 per 100 white blood cells. The Coomb's test was reported as negative on both the baby and the mother. The infant's Rh typing was CDE and the mother's Rh typing was cDE. At seven hours and twenty minutes of age the baby was given a transfusion of 70 cc. of group 0 Rh negative blood. The infant continued to have spells of cyanosis. Vitamin K, one ampule, and coramine, ¼ cc., was given to the infant. No further laboratory work was done on the baby. The baby expired at fifteen hours of age. Autopsy examination disclosed hepatosplenomegaly, along with 10 cc. of yellow fluid in each pleural cavity. Microscopic examination of the liver and spleen revealed erythroblastosis. The lung alveoli were filled with hemorrhagic fluid which was interpreted by the pathologist to be associated with erythroblastosis. Examination of the brain revealed no evidence of hemorrhage or kernicterus.

Committee comment.—This case illustrates the possible danger of relying upon a single laboratory diagnosis. A negative Coomb's test would certainly be unexpected in this instance. Therefore, the clinician should have confirmed the test by further testing. The new testing procedures which embrace the three factors of big CDE and little cde may explain the discrepancy in some cases.

Summary

The Hennepin County Neonatal Mortality Committee studied all neonatal deaths occurring in infants born in Hennepin County during 1952, 1953, and 1954. This involves 1,012 infants, including thirty-one sets of twins and one set of triplets, born to 988 mothers.

This report briefly reveals some of the findings of the three-year study, providing information on both premature and full-term infants, and presents some of the Committee's resulting opinions. It gives tables and interpretations on the types of delivery and duration of life of the 1,012 infants who died within the first twenty-eight days of life. In this paper the Committee, which conscientiously attempted to determine the primary cause of death in each infant, also gives a breakdown of the causes of death. Included in this breakdown of causes are abnormal pulmonary ventilation, which accounted for 60 per cent of the deaths noted in this study, congenital anomalies, infection, birth trauma, blood dyscrasia, and anoxia.

An analysis of the numbers and percentages of infants autopsied shows a gradual increase from 1952 to 1954. In 1954, autopsies were performed on 62 per cent of the premature and 88 per cent of the full-term deaths. Approximately 7 per cent

NEONATAL DEATHS IN HENNEPIN COUNTY

of the neonatal deaths noted in this study were judged by the Committee to have preventable factors. However, improvement in care may have been possible in an additional 17 per cent of the deaths. Brief case histories are given for four of these deaths, accompanied by a medical opinion on what procedures should have been followed to offset the factors resulting in death.

The Committee wishes to express its appreciation to the many physicians and pathologists who

so kindly co-operated by providing data on their cases and by providing records showing a consistently high percentage of autopsies.

Surgical Considerations in Acute Conditions in the Lower Abdomen

HARRY B. NEEL, M.D.

Albert Lea, Minnesota

THE DIAGNOSIS and treatment of acute conditions in the lower abdomen must engage the attention of every general practitioner, general surgeon and gynecologist. This is a field in which the physician must rely upon a careful history, a thorough examination and interpretation of the findings. Elaborate and complicated laboratory tests are usually not required.

To be satisfied with the diagnosis of "acute abdomen" robs the endeavor of much of its fascination and interest. One should strive to determine the exact pathologic process which has brought the patient to the physician. In addition to careful examination of the abdomen, the inguinal and femoral rings, the pelvis and the rectum should be examined.

In reviewing 1,267 cases of acute abdominal emergencies personally attended, it was found that 158 (12.47 per cent) were in the upper abdomen and 1,109 (87.53 per cent) were in the lower abdomen. Of the 1,109 cases of acute lower abdominal conditions, there were 727 cases of acute appendicitis.

The classic symptoms of this disease are now well known by both physicians and lay persons. It is the atypical case which may escape diagnosis and proper treatment, which is prompt surgical removal of the appendix. Localized tenderness is the most valuable single sign, and it may be elicited by rectal examination when abdominal palpation reveals no tenderness. Diarrhea is not a common symptom of appendicitis, but its presence does not exclude appendicitis, and the premature diagnosis of gastroenteritis may lead to disaster. The differential leukocyte count, which shows a shift to the left in nearly all cases of acute appendicitis, is a more valuable aid than the total leukocyte count.

Mesenteric lymphadenitis is the condition most frequently confused with acute appendicitis. It is an acute or subacute abdominal condition deserving special consideration in its own right. It occurs in young children and is characterized by the presence of large and numerous lymph nodes

in the mesentery and fluid in the peritoneal cavity. The symptoms are similar to those of appendicitis although usually not as severe; there is frequently a history of one or more mild attacks of abdominal pain, sometimes accompanied by nausea and vomiting. The point of maximum abdominal tenderness is variable. Tenderness on rectal examination is a nearly constant finding. In only about half of the cases does the differential leukocyte count show a shift to the left.

It has been said that the differential diagnosis of mesenteric lymphadenitis is purely academic. Appendectomy is the recommended treatment. In nearly all cases, symptoms are relieved and a cure is effected.

Intestinal obstruction is the second most common cause of acute symptoms in the lower abdomen, represented by 12.17 per cent of the cases in this series, nearly all of which involved the small bowel. Only occasionally does an obstruction of the large bowel require emergency treatment. As is well known, intestinal obstruction is characterized by intermittent crampy pain which may occur at regular intervals, nausea, vomiting, abdominal distention, increased intestinal sounds and inability to pass gas by rectum.

It is to be noted that seventy-eight cases, or more than half, were the result of hernias, a clear indication that examination of the femoral, inguinal and umbilical rings and incision scars is most important. The history of a previous abdominal operation and the presence of an incision scar should remind the examiner of the possibility of obstruction produced by adhesions or an adhesive band. Volvulus and intussusception are ordinarily accompanied by intense pain, sweating and shock.

The Miller-Abbott tube, which is my choice of the long tubes, can be employed satisfactorily in some inflammatory conditions, in the persistent ileus which occasionally follows laparotomy, and in selected cases of obstruction due to adhesions. When reliance is placed on intubation alone, one must be positive that the integrity of the bowel

ACUTE CONDITIONS IN THE LOWER ABDOMEN—NEEL

	Number	Per Cent
Upper abdomen	158	12.47
Lower abdomen	1109	87.53
Total	1267	100.

is not in jeopardy. Most patients with obstruction of the small bowel should be operated on promptly, however, after proper preparation, and the obstruction relieved by whatever surgical procedure is necessary.

The frequency with which diverticulitis of the colon is encountered is said to be increasing. In only a small percentage of cases is emergency treatment necessary. The perforation of a diverticulum may produce a localized or generalized peritonitis. The mesosigmoid may be long and the sigmoid may be on the right side of the abdomen. Operative treatment consists of either obstructive resection, proximal colostomy or drainage of the abscess.

In female patients, there are additional considerations in diagnosing the acute abdomen. Several years ago Swendson stated that "the cause of an acute lower abdominal crisis in a woman of menstrual age often cannot be determined without doing an exploratory laparotomy." As mentioned previously, every effort should be made to arrive at a correct diagnosis.

Ectopic pregnancy is the most frequently encountered acute condition in the female pelvis. Low abdominal pain, which may be fairly severe, is the most nearly constant symptom. The menstrual period may be delayed and, when bleeding ensues, it may be spotty, irregular or persistent. If there has been bleeding into the peritoneal cavity, the patient may complain of pain in the left shoulder. Tenderness is found on palpation of the lower abdomen and on movement of the cervix during pelvic examination. Some patients with ectopic pregnancy, when first seen, are in shock and present the signs of hemoperitoneum. Laparotomy and salpingectomy, with blood replacement as necessary, are indicated as soon as the diagnosis is made.

The symptoms and signs of bleeding follicle cysts simulate those of appendicitis, and occur at about the middle of the menstrual cycle and in young women. Although mild, they may recur time after time so that many of these patients see the

physician frequently. Operation should be avoided, if possible, but at times much blood is found in the pelvis; on a few occasions it has been necessary to place fine sutures in the ovary to control the bleeding.

Ovarian cysts may rupture spontaneously, producing sudden severe lower abdominal pain. Intraperitoneal hemorrhage may be profuse, accompanied by shock, pallor, and a distended and tender abdomen. On pelvic examination, if tenderness is not too pronounced to permit a satisfactory examination, the mass can be felt.

Ovarian cysts and tumors, leiomyomas of the uterus, the uterine adnexae and hydatids of Morgagni are subject to torsion on their pedicles. Except in the case of hydatids, the symptoms produced by the phenomenon are rather severe and dramatic. The intense crampy pain, backache, nausea, vomiting, tenderness, the presence of a palpable pelvic or lower abdominal mass should clarify the diagnosis. In one patient with torsion of an ovarian tumor, the uterus also had been twisted 180 degrees.

Acute salpingitis of gonorrheal origin is seen less frequently than formerly. Acute pelvic infection is characterized by chills, fever, vaginal discharge and extreme tenderness on low abdominal and pelvic palpation. Response to anti-

biotics is usually good. Surgery in the acute phase is not indicated.

Attention should be drawn to the fact that retroperitoneal hemorrhage due to anticoagulant therapy produces symptoms and signs of an abdominal emergency. Vigorous medical treatment is necessary to save the patient, who may be in profound shock. Surgical interference is of no avail.

Summary

The diagnosis of acute abdominal conditions is a problem for nearly every physician. This is a field in which the examiner must depend on his own senses and not rely too greatly on laboratory assistance. In the lower abdomen acute appendicitis, intestinal obstruction, mesenteric lymphadenitis and gynecologic conditions account for more than 90 per cent of the cases.

AMERICAN HEARING SOCIETY SURVEYS SERVICES AT LOCAL LEVEL

Hard of hearing children and adults across the country will benefit from the American Hearing Society's current survey of services offered by its member organizations, according to the agency's Executive Director, Crayton Walker.

Standards established by the society are aimed at improving and expanding local hearing programs, and securing additional chapters, as well as raising the standards of national services to the hearing handicapped.

Special effort will be made to improve the hearing aid evaluation and consultation services, which are an

important part of the program in many local hearing societies.

"Because of the growing demand for guidance in selection and use of a hearing aid," said Mr. Walker, "we are encouraging all of our member agencies to include such service, and to work more closely with hearing aid dealers in the respective communities."

On its national roster, the American Hearing Society now carries forty-three member agencies with professional staff, and fifty-three affiliates having volunteer workers only. Many of the member agencies, located in metropolitan areas, are included in the United Funds or Community Chests.

Counseling Parents of Mentally Retarded Children

HARRIET E. BLODGETT, Ph.D.

Minneapolis, Minnesota

THE AREA of counseling with the parents of mentally retarded children is one of great complexity. Mental retardation is, after all, a descriptive term which applies to a wide range of intellectual ability, includes a tremendous variety of behavioral characteristics and adjustments, and stems from a large number of possible causes. Since the mentally retarded child is found in families of all sorts, everywhere, in counseling we are dealing with a wide range of family situations and of adaptability of parents and siblings to the retarded child. What determines the problems the parents may face in living with their retarded child is affected more by the behavioral characteristics of the child and the flexibility and adaptability of the parents than by the child's intellectual ability.

Giving parents adequate understanding of the mentally retarded child should be considered as a series of interpretations, rather than just one. This series needs to include both the contributions of psychological and developmental measures, as assessments of the child's ability level, and pertinent medical studies, including neurological and sensory evaluations, important in ascertaining the underlying causes of the child's deficiency, evaluating the part played by sensory defects, and, increasingly important with the newer advances in medical treatment, in determining medical treatment which may contribute to the manageability of the child. Describing the child's ability level, as measured by psychological instruments, is a process facilitated by a basic policy of honesty and frankness, with information being presented sympathetically but factually. Parents very often are themselves able to participate in this interpretive

process, and such participation is most helpful to the professional person involved. What the parents themselves say in describing the child can be used by the examiner in discussion. Often it is helpful to ask the mother to demonstrate how she works with the child, and then to help her interpret the responses she has elicited. Many times parents are amazingly accurate in estimating the child's ability level, if they have come to feel comfortable and nondefensive in the interview situation. This is especially likely to be true if there are other children in the family so the parents have had daily standards for comparison.

Interpreting the child's present ability level, however, is not enough. The meaning for the child's future is the more significant thing. Many parents willing to accept the fact that the child is, as of now, "retarded" have not considered the implications this has for his future, and are convinced that he will later "catch up." Parents often can comprehend and understand the present level of the child, but are unable to project this into the future. Prediction is much more mysterious than measuring the child's present ability; parents can see the immediate situation, and can even accept the findings, but have not yet thought, or are not yet able to think, in terms of a permanent mental defect. Explanation of the ways in which we know human development to be consistently patterned is helpful. Often the use of a mental growth chart covering the developmental years, showing the child's present mental age performance, and then projecting this into the future to show the expected degree of later handicap, will make the process more clear. Many parents take several years to become convinced of the permanence of the defect and to realize what its later significance will be to the child; one function of adequate counseling is to attempt to make this information meaningful in advance so that parents may be spared the continuing disappointments and frustrations

Dr. Blodgett is Program Director, The Sheltering Arms, A Day School and Research Program for Mentally Retarded Children.

Presented at the University of Minnesota center for continuation study institute on "The Exceptional Child in Minnesota," October 2, 1956.

of not having their aspirations for the child's future development fulfilled.

With young children of preschool age, re-examinations are part of the process of interpretation, and contribute to a continuing process of step-by-step planning on the part of the parents. Again, it is important not to give the parents false hopes; a child in the severely retarded group can nearly always be identified with good accuracy, although one might not want to "label" him with a permanent IQ score at an early age. Less severe degrees of retardation may call for more caution in interpretation, but letting the parents in on the fact that he is somewhat retarded, and that this is probably a permanent handicap, is the wise course. Parents accept the recommendation for a re-evaluation well when it is explained as offering opportunity for a further kind of comparison. The first test tells us where he is now; the second one tells us where he is then, plus permitting a study of his rate of development in the interval between the two measurements. Even though long-range prediction should not go beyond knowledge, early interpretations to parents are of extreme importance not only in helping form their attitudes toward the child's future, but also in helping to modify their attitudes toward him and their expectations of him at the present. Many emotional and behavioral problems in retarded children are the result of unrealistic demands made by their parents, often in an attempt to "force" the child into normal development.

In the step-by-step planning, discussion of commitment to state guardianship as mentally defective, as a protective measure for the child, should come relatively early. Parents need time to think about this, quite apart from the possibility of the child's later need for institutional care. They need to know that commitment is not the same thing as placement in an institution; they need to learn to think in terms of the agencies and consultative services which will be available to them in making choices and decisions.

There is no formula for knowing how much information, at what pace, should be given to individual parents. Experience indicates that some parents can absorb a great deal of information, while others need to progress at a much slower rate. In general, if the first discussion covers the facts of the child's retardation, begins the expla-

nation of commitment, and gives a little idea of the implications of the retardation for the child's future, it is probably enough. Later sessions should be arranged as problems arise, provided the parents feel free to seek further help at critical moments. Some things which can be suggested in the course of several discussions with the parents should include: the child's need for constructive things to do; his need for close supervision; his need to acquire physical independence, good basic habits, and good social habits; the possibility that later on he might be unhappy at home or in the community because of his inability to compete or to find a niche for himself; the need of the family to consider other children, and themselves; ways in which others have been mutually helpful (i.e., local groups of the Minnesota Association for Retarded Children); ways of handling specific problems of behavior; and, all through the processes of counseling, the fact that there is no one "right" solution; that each family faces different constellations of problems.

Parents show many reactions to learning that their child is mentally retarded. Some parents reject the diagnosis, and go home to protect and overprotect the child. Some who reject the diagnosis respond by a determination to "make the child be normal;" this is likely to produce additional problems of adjustment for the child. Some accept the diagnosis, but react to this with a rejecting attitude toward the child. Others, accepting of the fact of the retardation, try to overprotect the child, feeling that this will conceal his defect. Many parents, however, are able to accept the diagnosis realistically and go home to handle their situation realistically. Differences of opinion between parents pave the way for increasing conflicts. Since the accepting parent is likely to seek more information, and the non-accepting parent does not, the gap between them continues to widen and the problems may multiply. Other children may suffer through parental unequal division of time, attention, and interest; the normal child may be expected to assume too much responsibility, or may have too many limitations put on his own activities. Perhaps he is expected to compensate for the presence of the retarded child, and achieve twice as much. Since children take attitudinal cues from their parents, confusion in the parents is apt to be communi-

Symptoms and Signs of Heart Disease

Clinical Approach to the Problem

ARTHUR C. KERKHOF, M.D.

Minneapolis, Minnesota

THE MOST common symptoms associated with heart disease are: pain, dyspnea, edema, tachycardias, arrhythmias and syncope.

Pain of cardiac disease may be of four types: anginal, mitral, pericardial, and pain of infarction. Anginal pain is usually substernal, radiating to one or both arms but may also radiate to the neck. It usually is produced by exertion or excitement and is relieved by rest very shortly. It is immediately relieved by nitroglycerin used under the tongue. Mitral pain usually occurs after exertion. It is located near the apex, and it may remain for some time. It does not radiate and, as a rule, it is not relieved by nitroglycerin. Pericarditis produces retrosternal pain of a rather constant type. There is no radiation as a rule, and it is not relieved by nitroglycerin. The pain of myocardial infarction is similar in locations and radiation to anginal pain. It is not as a rule brought on by exertion, nor is it relieved by rest. It may last for hours, is more severe than anginal pain and is not relieved by nitroglycerin.

The pains associated with heart disease must be differentiated from those produced by hiatus hernia, chest wall difficulties, pleurisy, cervical outlet irritation, so-called "heart burn" and esophageal spasm, pulmonary embolism and functional disorders. Although a gastrointestinal x-ray is not always successful in finding a hiatus hernia most of these lesions will be discovered by careful examination with that method. Chest wall difficulties as a rule can be differentiated by the fact that there is definite tenderness to pressure, whereas heart pain itself is not produced by pressure on the chest wall. Pleurisy will have the typical pain related to breathing and is relieved by holding the breath. It usually, therefore, is differentiated both by history and by reason of the friction rub which may or may not always be heard. Irritation

of the cervical nerve rootlets in the cervical spine is not an uncommon condition. Examination for this bony difficulty can be made by x-ray, and proper x-rays may show definite impingement upon nerve rootlets. Although esophageal spasm and "heart burn" produce very definite retrosternal pain at times, they are not as a rule produced by exertion. They are usually relieved by belching and antispasmodics will usually also give relief. Pulmonary embolism can cause pain but usually is differentiated by the fact that there is a cause for a pulmonary embolism in the sense of some thrombotic episode in a vein or by reason of the fact that the patient coughs up blood with the episode. Functional chest pain, of course, is the most common chest pain of all. It would appear that over 50 per cent of all individuals who complain of pain in the chest have that pain on a functional basis and not on the basis of organic disease. Careful history plus the absence of organic findings will lead one to make such a diagnosis.

Dyspnea of cardiac origin is usually one of two types; it can occur on exertion and may be relieved by rest. It may occur during the night as a result of a drop in blood pressure or an exciting dream state. It may also take the form of orthopnea. Cardiac dyspnea must be differentiated from the dyspnea due to improper breathing habits, hysteria, asthma, emphysema, acidosis and air hunger due to lack of oxygen in the atmosphere or lack of oxygen carrying capacity.

Edema of cardiac origin, a sign of right heart failure, is usually dependent. It is almost always associated with an increased venous pressure, except in those cases where the patient is beginning to recover and the edema has not entirely disappeared. Cardiac edema must be differentiated from that due to varicosities and that due to lowered blood albumin, as in nephritis and starvation states.

Synopsis of remarks made at Continuation Course in Cardiovascular Disease, University of Minnesota, March 19, 1956.

Tachycardias and *Arrhythmias* are of course all cardiac in that the heart is involved, but they do not necessarily indicate cardiac distress. Premature beats, simple tachycardia, paroxysmal tachycardia and paroxysmal auricular fibrillation are usually nonpathologic. Many of these can be diagnosed by a good history and very minimal examination.

Syncope is usually due to a marked slowing of the heart rate either by a vagus effect, as in fainting, or by a complete heart block with a very slow ventricular rate. Differentiation between these is simple.

The signs of heart disease are found on examination. Although dyspnea, obviously, as a rule, is a symptom, at times the patient does not realize this dyspnea, but it can be seen definitely on inspection. Edema, of course, is also a sign in the sense that it is easily recognized by inspection and palpation. Cyanosis may be a sign of heart disease and, certainly, is a sign of decreased oxygenation of the arterial blood and, as a rule, will be seen on inspection. Palpation will also reveal the presence of thrills which may be a definite

sign of heart disease, and will reveal enlargement of the liver if that is present. Auscultation of the heart for murmurs is important, as is the auscultation of the lungs for rales which could indicate the presence of lung edema. Enlargement of the heart is a very important sign of heart disease. Any cardiac enlargement greater than 10 per cent over the Clark-Ungerleider tables must be considered abnormal. The shape of the heart is also determined by x-ray. Any abnormal shapes, such as occur in mitral disease or left ventricular heart disease, can easily be determined by that method. *Arrhythmias* may frequently be determined by auscultation or palpation of the pulse at the wrist but in complicated cases an electrocardiogram becomes necessary. The electrocardiogram also will determine the presence or absence of myocardial abnormalities. Blood pressure determination is of very definite value, although at present there is a very strong indication that our previous upper limits of normal blood pressures were probably lower than they needed to be. It must be remembered that we now are accepting values considerably higher than those previously accepted as normal.

ESTABLISHMENT OF A BLOOD VESSEL BANK

(Continued from Page 698)

Certainly, special precautionary care to assure aseptic technique during the sterilization of the graft is an absolute necessity and should therefore be entrusted only to one thoroughly familiar with aseptic procedures. The cultures taken to check the sterility of the graft give one assurance of sterility only at the time the culture was taken. A later break in technique can invalidate this safeguard and cost the life of the recipient of the graft. This is one more area of surgery with no room for error.

Editorials

JOHN F. BRIGGS, M.D.
ARTHUR H. WELLS, M.D.
HENRY G. MOEHRING, M.D.

WILLIAM H. FELDMAN

The tuberculosis-control program in America never has been an exclusive battleground for physicians only. Rather, every dedicated worker has always been welcomed, and the diverse composition of the antituberculosis army has been one of its greatest strengths. No better example of this can be found than the career of William H. Feldman, D.V.M., M.S., D.Sc. (honoris causa), professor of comparative pathology in the Mayo Foundation, Graduate School, University of Minnesota, who was cited by the Minnesota State Medical Association on May 14, 1957, for "Distinguished Service to Medicine."

Trained in veterinary medicine, Dr. Feldman soon became interested in the problem of tuberculosis in animals, and began his work in this field while he was a member of the faculty of Colorado Agricultural College. When he joined the staff of the Institute of Experimental Medicine of the Mayo Foundation in 1927, he concentrated on the study of naturally acquired and experimentally induced tuberculosis in animals. His experience in this field led to the pioneer work in the chemotherapy of experimental tuberculosis which was carried out with his colleagues, Dr. Frank C. Mann and Dr. H. Corwin Hinshaw. In due course, the effect of streptomycin on tuberculosis in guinea pigs was demonstrated, and this led to the clinical studies which have revolutionized the treatment of this disease.

Many honors have been bestowed upon Dr. Feldman for his work. In 1946, he delivered the Harben Lectures at the Royal Institute of Public Health in London. In that same year, he was presented with the Pasteur Medal by the Pasteur Institute in Paris, and with the Alvarenga Prize by the College of Physicians of Philadelphia. The Mississippi Valley Conference on Tuberculosis awarded him the Hoyt Dearholt Medal in 1953, and the National Tuberculosis Association named him the Trudeau Medallist for 1955. The most recent honor was the Distinguished Service Medal of the American College of Chest Physicians, given to Dr. Feldman at the 1957 meeting of the college.

These many honors have been richly deserved by this devoted scientist, but those who know Dr. Feldman best realize that his greatest reward has been the inestimable contribution which chemotherapy has made to the control of tuberculosis throughout the world.

DAVID T. CARR, M.D.

SPECIAL PILOT PROJECT IN MENTAL RETARDATION

A pilot project to discover what a multidisciplinary team approach, consisting of a pediatrician, public health nurse, welfare worker, social worker, psychologist, and any indicated consultants, will reveal as to the whereabouts as well as the physical, emotional, and social needs of mentally retarded children in rural counties has been undertaken by the Minnesota Department of Health in cooperation with the Minnesota Department of Welfare. The study is one of a number being financed by special grants from the U. S. Children's Bureau to state health departments. It has been reviewed by the Council of the Minnesota State Medical Association and is receiving their active cooperation.

The project is limited to four counties in west central Minnesota—Becker, Clay, Otter Tail and Wilkin, with headquarters at Fergus Falls, in close connection with the District Health Office and the state mental hospital. The staff will consist of a medical director, pediatrician, public health nurse, welfare community worker, social worker and a psychologist. The staff will work closely with local physicians, county welfare workers, teachers, ministers, public health nurses and parents. It earnestly requests the active interest and co-operation of the local medical societies, school authorities, welfare agencies, and other interested official and voluntary groups. The study will continue for four years.

This special project will serve a dual purpose: (1) to determine what can be done in rural counties as a part of the community responsibility to improve local services for the mentally retarded and to minimize the necessity for institutional

care; (2) to stimulate and foster the development and operation of community services for retarded children and their families in rural areas throughout the state. The first step will be to locate all retarded children in the four counties in the study; next, to secure adequate diagnoses and treatment through a medical-psychological-social work approach; and finally, a program of group socialization through day care centers, camping groups, scout troops and other indicated activities and facilities within the capabilities of these children. Some, who are trainable only, may receive individual services within their limits; the educable group will be prepared for the classes for exceptional children made possible by the last legislature.

The state-wide advisory committee for the project includes: Dr. Maynard Reynolds, Dean M. Schweickhard, Dr. Harriet Blodgett, Frank M. Rarig, Jr., Dr. E. J. Engberg, Dr. George Logan, Roberta Rindfleisch, Alberta Wilson, Mrs. F. C. Adair, and Dr. George Williams. Dr. A. B. Rosenfield, director of the division of special services of the Minnesota Department of Health and Dr. Dale C. Cameron, director of the division of medical services of the Minnesota Department of Welfare are ex-officio members.

Minnesota Department of Health

d-TUBOCURARINE IN MAN*

The clinical use of muscle relaxants has increased many fold during the past decade and marks one of the great advances in the field of anesthesiology. At the same time, there exists a paucity of experimental study both on the action and of the fate of these compounds in the body.

A study of the effects following the intravenous injection of large amounts of d-Tubocurarine was carried out on seven unanesthetized volunteer subjects. Biochemical analyses of blood plasma levels of curare were measured with the aid of a newly developed ultra-violet spectrophotometric technique.

The elimination of curare by the body with the passage of time revealed that 25 per cent of the originally intravenously injected dose (0.1 mg. curare per pound of body weight) was still present in the plasma one hour after its administration.

*Abstract of a thesis presented at the Minnesota Academy of Medicine, February 13, 1957.

This plasma level of over 1 gamma per cubic centimeter was not discernible by clinical measurement of vital capacity which had already returned to normal levels. This residual curare level constitutes a hidden danger to the apparently recovered post anesthetic patient. The effects of narcotics given for postoperative pain relief added to the residual plasma curare may combine to push the patient into severe respiratory depression.

A study of the overall respiratory depressant action of curare showed close correlation between plasma concentrations of curare and reduction of measured vital capacity. Levels of curare above 4 gamma per cubic centimeter of plasma produced severe degrees of respiratory depression. No significant hemodynamic changes could be demonstrated following the intravenous injection of curare in the unanesthetized subjects.

The action of anti-curare compounds on the plasma levels of curare showed that both edrophonium (Tensilon) and neostigmine produced a temporary reduction in plasma curare concentrations and a concomitant improvement in measured vital capacity. The action of the former compound is outlasted by the residual curare effects.

ELLIS N. COHEN, M.D.

RESEARCH AND THE MINNESOTA HEART ASSOCIATION

Few volunteer health organizations can look back on the first decade of their operations with as much justified satisfaction as can the Minnesota Heart Association. In dollars and cents terms, it has grown from an annual income of \$30,000 to over \$500,000. Its annual investment in research on the causes, prevention and treatment of cardiovascular diseases has grown from \$5,000 in 1949 to \$317,732 in 1957. Its contribution to professional and lay education in matters pertaining to the circulatory system in health and disease has grown proportionately. A little more than 50 per cent of the two and a quarter millions raised has gone into research and the remainder aside from organizational expenses can be credited to specific educational projects and community services. Even the organizational and fund-raising activities are largely educational in nature and cannot be ignored in the total impact of the organization upon the community. For example, it is a virtual certainty that community-

vide support for U. S. Public Health Service appropriations for cardiovascular and other medical research has been greater because of the educational role of the Heart Association.

This is a point I should like to develop further. Medicine today is in the process of great ferment. The twentieth century has witnessed the greatest change in the art of healing and of disease prevention that has ever occurred. More progress toward solution of health problems has occurred in the last hundred years than in the whole of the prior ten thousand years, the approximate span of recorded human history. The last half of the nineteenth century saw the establishment of the germ theory of epidemic and contagious diseases. Sanitation and related measures, including artificial immunization, as for smallpox, began the process of wiping out the epidemic scourges of mankind. In the nineteenth century, too, the developments in anesthesia and aseptic surgery set the stage for the surgical advances of later years. The rise of scientific pathologic anatomy also played a major part in making medical practice the art of applying science to disease.

The twentieth century has seen the application of physics and chemistry to health problems in a major way. Mention of the x-ray, radium emanation, electrocardiography, electroencephalography will indicate some of the roles of physics. Mention of vitamins, metabolic diseases, endocrinology, chemotherapy, antibiotics will indicate the range of applications of chemistry.

These developments, which have been occurring at an ever accelerating pace, have not been due to accidents in any true sense. They have occurred because an increasing number of persons of high intelligence and great native curiosity have devoted their lives to searching out the secrets of nature. The twentieth century is an age of science, in medicine as in technology, because Society has begun to realize that scientific research is the only way we know to progress in knowledge about how to control the forces of nature in the interest of human welfare.

This is where the Minnesota Heart Association comes into the situation. Its emphasis on the crucial role of research in the solution of the human problems of heart and vascular diseases has played and is playing a major role in educating the people of Minnesota with regard to the practicality of the impractical. All basic research is impractical. It is useless in the eyes of all ex-

cept those who see that knowledge is never ultimately useless.

A great change has occurred in recent years in public attitude toward the support and encouragement of scientific research. The public has accepted the thesis that research is sufficiently likely to be able to solve important problems, in many fields but particularly in medicine, so that investment in it is the prudent thing to do.

In the Minnesota Heart Research Program, we have seen such support pay off. The Minnesota Heart Association is in no small measure responsible for the development of open-heart surgery. It has aided numerous investigators in studies of the fundamental and applied problems in this field. It has supported a half dozen separate studies of the role of fat and steroid metabolism in relation to the state of health or disease of blood vessels. It has supported studies on the most intimate chemistry and structure of heart muscle. It has supported work aimed at elucidating the mechanisms of circulatory shock. It has aided in studies of transport of materials across membranes. It has assisted in studying the role of heredity in heart disease. During the current year it is assisting sixty-three separate research projects on problems ranging from electron microscopy and enzyme chemistry to clinical applications of physiology, chemistry and physics to diagnostic and treatment problems. For the coming year, your Research Allocations Committee has recommended support of forty-four such projects and four research fellowships. The work will be done in five separate institutions.

The first ten years of the Minnesota Heart Association have coincided with and have been in no small way responsible for the great upsurge in cardiovascular research in the State of Minnesota. As a medical scientist I want to pay my tribute to the intelligent public spiritedness of the many lay men and women who have made this development possible. Especially, I want to salute the Minnesota Association of Life Underwriters for their tireless efforts. I am sure that not only my medical colleagues, but that every person in the community who knows by personal experience or close contact with heart disease what the human stakes are will be grateful that the staff and the members of this corporation are moving forward for even more fruitful investment in research in the next decade.

MAURICE B. VISSCHER, M.D.

CONFESSIONS OF A HOBBYIST

Photography

Some time about 1900, I started taking pictures with a big, clumsy "Hawkeye" box camera and dry plates. The 4 x 5 Stanley plates cost 49 cents a dozen, and a boy had to save up some time for a box of those. Then, except for some snapshotting of the drugstore variety, there was no photography until the late 30's, when Mrs. Briggs gave me a 35 mm. Retina camera for my birthday. That started it again. The Retina was superseded by a Leica, bought in the free port of Curaçao, in the West Indies, and I started on a career of developing and enlarging. I became so enthusiastic that I got bad metal poisoning on my fingers from the developer, and learned the hard way to use tongs. I still use tongs for prints, but I find that for films a hand lotion containing silicone is adequate protection.

35mm. photography is wonderful for making a family record of children. One can shoot a whole roll without pain to the budget, and black-and-white prints, if properly processed, are permanent. This is not true of color. Nobody ever made a permanent aniline dye, and even the best transparencies begin to fade after ten or twelve years. The new Tri-X film is so fast that one can snap and snap indoors. Last Christmas, I shot a whole roll as children and grandchildren were opening their presents, and there were enough good ones to make a delightful record of the occasion.

While not so permanent, color transparencies, to be projected on a screen, are charming. At this point, I conceived the idea of taking closeups of wild-flowers in their natural habitat, which is much more satisfactory than making a pressed and dried herbarium. This, in turn, led to making dye-transfer color prints of the best of the 1,100 color slides that we now have. Flower photography outdoors, close up, is very difficult. The light is never right. Everything is bathed with invisible green light from surrounding vegetation, and because color film is slow, and closeups require longer exposures, one is frustrated by the fact that the things don't stand still. The exposure, too, must be very accurate, or the colors are not right. People are very lenient about black-and-white pictures, but they will look at a color shot on which you have labored and sweated and say,

"Yes, but was it really as blue as that?" I now take extreme closeups indoors, with controlled artificial light. Some tiny, inconspicuous flowers, taken so that one bloom fills the whole frame, enlarge into gorgeous things. The business of making color prints from these transparencies is more than enough for another chapter.

JOHN DEQ. BRIGGS

THE STEEL ENGRAVED BOOKPLATE

In the foregoing articles in this series, the antiquity of the bookplate was outlined, the customs of collecting and exhibiting, the famous depositories, the size and material, and two methods of making the plates and prints.

As for the steel engraving, the cost depends on the intricacy of the design. Because all cutting must be done by hand, plenty of time must be allowed for this sort of engraving, perhaps two months. Each order taken by an engraver of steel must take its turn. Moreover, because this art is such a tax on nerves and eye, the steel engraver must be allowed to lay one client's work aside from time to time in order to concentrate on another quite different. He must cut all lettering backward and the entire design in the same way, and all detail must be perfectly rendered if he is to satisfy his client and himself as an artisan.

In preparing a drawing for a steel engraving, the black and white original must be made exactly the same size as the finished steel engraving is to be, rather than four times as large as in the case of the zinc etching or the copper plate. Furthermore, the drawing must be rendered in precise detail, as the engraver of the steel plate will copy it exactly as he finds it. The method of printing from this plate is the same as from the copper plate—by hand. The cost at present is approximately \$15.00 a hundred, including stock which is usually a Japanese parchment. Shidzuoka vellum is the kind often used. The cost of cutting the plate is the chief item. It will range from \$100.00 to \$250.00.

In choosing the non-gummed papers, one must merely remember that the back of each print will have to be pasted separately at the time they are put into the books. This is a long piece of work, but it can be done by using newspaper squares on which to lay the prints, face down. The newspapers are cut into pieces about the

ze of one's hand and each piece is discarded immediately after using. In this way, the paste from the edges of the preceding print will not be transferred to the face of the next one. The books are left open on the floor for several hours after entering the prints, so that the first few leaves will not become damp.

Work will go faster if one person pastes and another puts into place. One must be sure that the prints are pasted to the very edges, particularly the corners, and that the entire back surface is covered with the paste. The prints are placed absolutely straight. They do not go at center of the fly-leaf but at center of the inside of the stiff cover. The back of the finger-nail will help a stubborn corner to lie flat and will not injure any paper. There is a "Non-warp Paste" on the market which is particularly effective for this type of pasting. It can be bought by the pint at \$1.35, or by the quart at \$2.00, and will keep fresh in the ice-box for months. This is made by the B. H. Fuller Company of Saint Paul. It is in clear, round, glass jars with a screw top. As this company makes many kinds of glues and pastes, the description is given in full. To go with this paste, an artist's flat, half-inch brush with white bristles, procurable at 40 cents, will serve very well by cutting off half the handle.

CLEORA WHEELER

Designer and Illuminator

CALENDAR HISTORY

Although Brown & Bigelow has ventured into all types of advertising specialties, it still remains the foremost calendar maker in the world, turning out 60 million calendars a year to make this item still its No. 1 product.

In its first year of operation, 1896, this company had a total business of \$13,000. By way of comparison, the same firm in 1956 grossed more than \$55 million. Its greatest growth has been under President Charles A. Ward who rose to head the firm in 1933 after starting eight years before as a factory bench hand.

While most of us are familiar with the conventional calendar block containing the months, it was only after 1900 that this type came into use.

Since then, calendars have branched out into

all types and are made of various materials. Metal and plastic calendars in addition to paper products are turned out by the hundreds of thousands by Brown & Bigelow. Calendars are fashioned for the home and even for various rooms in the home. They are made for office, for desk, for wall and for personal use.

For the housewife, Brown & Bigelow has developed the pocket calendar. Here in handy little pouches can be kept recipes, grocery slips and other household records. For the farmer, too, the pocket calendar comes in handy as a convenient place to file away his stock and crop records and other farm information to keep him posted on his operation.

Another type which is a household favorite is a color-picture, multiple-sheet calendar with handy household hints and recipes. The religious calendar—Catholic, Protestant or Jewish—was developed by Brown & Bigelow. Varied types of personal calendars for billfolds, desk or purse are also manufactured in the constant search for calendars which emphasize utility.

These specialized calendars are in addition to the many common hanging calendars which feature the works of the world's great artists both in oil and water color. Colored photograph calendars feature all types of subjects.

There are pictures for the mother, for the outdoor enthusiast, the lover of flowers, dogs, children—all types of pictures which will both enhance the calendar and be a "stopper" for a customer, in the Brown & Bigelow line.

In addition, Brown & Bigelow turns out thousands of tailor-made jobs for many of America's largest railroads and industries. The Great Northern, Burlington, Monon, Spokane, Portland & Seattle, Texas and Pacific, and others order special calendars from the firm.

Pan-American and Northwest airlines use Brown & Bigelow specials, as do also large firms such as Minneapolis-Moline, Allis Chalmers, Massey-Harris, International Harvester, Massachusetts Mutual Life, U. S. Royal, Kelly-Springfield, Westinghouse, Hotpoint, J. I. Case, Deere & Co., Sylvania Electric, Libbey-Owens-Ford, Sun Oil, Youngstown Sheet and Tube, General Tire, Fisk, Allen-Bradley, Worthington Corp., Austin-Western, Dr. Pepper, and a host of others.

The special jobs are designed for farm, home and office and for the export trade. These big

calendar runs are from 10,000 to a million pieces and are prepared a full year in advance.

The pocket type calendar has a distribution of more than 5 million pieces.

JOSEPH H. SUMMERS
Brown & Bigelow

FOREIGN MEDICAL GRADUATE EDUCATION

The United States helped meet the world's need for better medical care last year when more than 6,700 foreign interns and residents from eighty-eight countries around the world trained in American hospitals, according to a survey recently released by the Institute of International Education. Of this group, 4,753 served as residents and 1,988 trained as interns in hospitals throughout the United States.

An increase of 10 per cent over the previous year, the substantial rise was due chiefly to the greater number of young physicians coming here from the Far, Near and Middle East. More than two-thirds of these doctors traveled from these areas and Latin America, reflecting the deep need in these countries for improved medical care and the lack of local training facilities.

Medical men, as usual, outnumbered medical women. Only 908 (13.5 per cent) of the total group were women, with the Philippines sending more women proportionately than other countries.

In seeking the top-caliber medical training available in the United States, these young medical students were scattered throughout forty-four states, the District of Columbia, Hawaii and Puerto Rico. However, most of them (75 per cent) were concentrated in ten states, with one-quarter of them in New York State hospitals, and one-half of them in hospitals in Ohio, Illinois, Massachusetts, Pennsylvania, New Jersey, Missouri, Maryland, Michigan, and Texas.

The four hospitals with the largest group of foreign interns and physicians were Bellevue in New York City, Boston City in Boston, Medical Center in Jersey City, and Henry Ford in Detroit.

The Institute survey, called "Open Doors" and conducted annually to determine the number of foreign students, physicians, and scholars studying in our country, also reported 3,854 foreign students studying in the various medical sciences—dentistry, medicine, nursing, pharmacy and premedical studies in United States colleges and universities. This represents about 9 per cent of the total num-

ber of foreign students (40,666) in the United States for 1956-57.

The "Open Doors" survey also reported on the number of American students studying medicine abroad during the 1955-56 year, with the largest concentrations in Europe and Canada. Of the 996 students from the United States studying in Switzerland, 669 were in the field of medicine; 319 Americans were pursuing medical studies in Italy; 174 in the Netherlands, and 293 in Canada.

The number of foreign and American medical faculty members who participated in the exchange movement last year was relatively small. One hundred eighty foreign medical scholars came to the United States and eighty-one American faculty members in the field of medicine went abroad. The latter figure, however, represents an almost 100 per cent increase over the forty-five American medical faculty personnel who went abroad the preceding year. This increase could be indicative of a trend on the part of the American medical profession in establishing medical exchange as a two-way road.

Institute of International Education

COUNSELING PARENTS

(Continued from Page 722)

cated to the normal children, with consequent emotional hurdles for them.

Parents whose child is multiply handicapped often have special needs in counseling. If any sort of physical or health problem has been presented, as is the case, for example, with a cerebral palsied child, it is natural that the parents have focused their attention on the more visible and care-requiring physical problems. To find that the child has the additional handicap of mental retardation is often an entirely new idea to them, and hence additional time for discussion may be needed.

In counseling the parents of mentally retarded children, as in any other area of social interaction, it is unrealistic to expect complete success. We need to expect degrees of success and degrees of failure, and to anticipate realistically that, despite our best efforts, we will sometimes fall short of our goal. As a basic procedure, however, success can most often be expected when counseling includes the honest, sympathetic giving of factual information in ways which can be understood, on a time dimension which permits repeated contacts and includes gradual planning.

President's Letter

COST OF MEDICAL CARE

Much has been said and written about the high cost of medical care. As so often proves to be true, however, when the facts are assembled and carefully analyzed, it becomes obvious that the increase in the cost of medical care actually has not kept pace with the increase in the cost of other services or facilities or goods. It is well to call this to the attention of those who are discussing this problem. In this respect, it would be eminently worth every physician's while to read the recent analysis of this problem by Dr. Frank G. Dickinson, director of the Bureau of Medical Economic Research of the American Medical Association. He found that the total spent for medical care in the United States in 1956 was \$12,106,000,000. This sum included expenditures for hospital care, drugs and sundries, dentists' services, physicians' services and all other forms of medical care. Of this amount, \$3,269,000,000 was paid for physicians' services, and \$3,451,000,000 was paid to hospitals. It is worthy of mention that in that same year \$9,360,000,000 was spent for alcoholic beverages and \$5,681,000,000 for tobacco. The year 1955 was the first in which the number of dollars spent for hospital services was greater than the number spent for physicians' services. This situation also obtained in 1956.

Actually, it was found that that portion of the medical-care dollar paid out for physicians' services decreased between 1952 and 1955. Whereas in 1952, 28.5 cents of each medical-care dollar went to physicians, in 1955 only 27.2 cents was spent for physicians' services. Moreover, it is worth mentioning that in 1956 consumers spent \$3,581,000,000 for personal articles or care, such as toilet articles and services in barber and beauty shops and baths—far more than was spent for physicians' services during this year. These are impressive facts, and they should be known by physicians generally.

Now, to turn to a situation in Minnesota more or less closely related to this problem of the cost of medical care, I should like to dwell for a moment on a matter which affects every physician in the state. From time to time, attention is called to the fact that the yearly expenditures by the state of Minnesota for medical care under the provisions of the Old Age Assistance Plan are gradually increasing. Last year that figure was \$17,000,000. It should be stressed that in this particular instance the so-called medical care includes such broad factors as expense of hospital care, nursing homes, drugs, dentists and all other services, and that only 11 per cent of the total amount actually went for physicians' fees. This stresses the fact that the term, "medical care," can be very misleading. Probably a better appellation, and one more nearly accurate, would be "health care." I wish to make it very clear that I am not trying to condone the ever-increasing costs of living in the United States, and neither do I consider it necessary to be an apologist for physicians. I do believe, however, that it is worth while to point out that the costs of medical care, and particularly physicians' fees, actually are lagging behind the general increase in the costs of living.

It is important, also, to remember that physicians are not so voluble, not to say verbose, as are certain members of some groups who seem to be unwilling or unable to perceive that the fee received by the physician is a very small part of that impressive aggregate spent annually for what is designated by the ambiguous term, "medical care."

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is fluid and cursive, with a large loop at the end of the last name.

President, Minnesota State Medical Association

Committee Action

A Case-Finding Program for the Control of Tuberculosis in Minnesota

Your Tuberculosis Committee suggests the following case-finding methods, many of which are being carried out at the present time, which should develop into a good comprehensive and sustained tuberculosis control program in Minnesota and possibly lead to the ultimate eradication of the disease:

Accreditation of Minnesota Counties for Human Tuberculosis Control

This accreditation program was established in Minnesota in 1941 and is sponsored by the State Medical Association, the Minnesota Department of Health and the Minnesota Tuberculosis and Health Association. The qualifications of the accreditation program are as follows:

1. The death rate from tuberculosis must be 10 or less per 100,000 population for a period of five consecutive years.
2. At least 90 per cent of the seniors in the high schools in the county must have been tuberculin tested, with a reaction rate of 10 per cent or less.
3. At the present time, sixty-five counties of the eighty-seven have met the accreditation qualifications and of the twenty-one counties not yet accredited, all but three have met the first qualification—having a death rate less than ten per 100,000 population.

Your subcommittee recommends that the accreditation program be continued on an accelerated basis to bring about a situation as soon as possible whereby all of the eighty-seven counties in the State of Minnesota have been accredited. The Minnesota Tuberculosis and Health Association is currently engaged in speeding up this accreditation program.

The committee further recommends that when the entire State of Minnesota has been accredited that steps be taken immediately to set up more rigid standards of qualifications.

It must be constantly emphasized to the general public that when a county has met the present qualifications of accreditation in tuberculosis control, it does not mean that said county has completely eliminated the tuberculosis problem but that it be construed as a milestone in tuberculosis control. Raising the standards of qualifications will help to keep the general public informed on the fact that tuberculosis is far from being eradicated and thus help to dispel apathy.

*Accreditation of Minnesota Counties
School Certification
Tuberculin Testing Surveys
Routine X-Ray Examinations
Routine Tuberculin Testing*

School Certification

The committee recommends that the Certification of Schools by the American School Health Association be continued in Minnesota. The qualifications in Minnesota for certifying schools in tuberculosis control were prepared by a subcommittee composed of Dr. E. A. Meyerding, Chairman, Dr. Lewis Jordan and Dr. S. A. Slater, in 1945, and are as follows:

Class "A" Certificate

1. From 95 to 100 per cent of the children have been tested at least every other year.
2. All reactors in high school have been x-rayed. (It is strongly recommended also that reactors among grade school children be x-rayed.)
3. All non-reactors throughout the school shall be retested every two years, preferably every year.
4. All personnel and employees of schools shall be tuberculin tested. Reactors shall be x-rayed, and non-reactors retested every two years.
5. All students and personnel who have progressive tuberculosis must be removed from school until adequate treatment has been administered and the danger of contagion is remote.
6. An educational program shall be a requirement for teachers.

Class "B" Certificate

The same requirements as for Class "A" except that only 80 to 95 per cent of the children from the kindergarten through high school are tuberculin tested.

Keeping a permanent record of the rate of tuberculosis infection in children and tracing the source of infection is of tremendous value as a case-finding method.

Community-wide and County-wide Tuberculin Testing Surveys

This committee strongly recommends that the community-wide and county-wide tuberculin testing be continued in the State of Minnesota.

To date, four counties—Meeker, Lincoln, Lyon and Kittson, have had a county-wide tuberculin testing survey. Cottonwood County is being tested at the present time.

To date, there have been several community-wide surveys—the most prominent and biggest being the city of Hastings with a population of some 6,500 persons.

It is reasonable to assume from a study of the results of the mass tuberculin testing done thus far, that an overall 25 per cent of Minnesota's 3,000,000 plus persons, or about 750,000, are reactors to the tuberculin test. In other words, we have approximately 750,000 persons in Minnesota who are harboring the germs of tuberculosis—a huge reservoir of tubercle bacilli—fantastically large when compared to the infinitesimally small reaction rate in cattle, which is less than 2/100 of one per cent (two in 10,000).

It is strongly recommended that this mass tuberculin testing be speeded up in some manner so that the people of our state can avail themselves of this case-finding program. Certain obstacles exist that make it difficult to speed up a program of this kind and one of the main difficulties is the lack of x-ray facilities at a reasonable cost. Another difficulty is the limited nursing service which prevents adequate follow-up of those found to react to the tuberculin test.

This committee feels that it is of paramount importance that the persons in Minnesota who are harboring the germs of tuberculosis be identified, not only in the interest of their own health but also because it would give the official health agency accurate data as to the tuberculosis situation in our State of Minnesota.

Routine X-Ray Examinations of Hospital Admissions

We wish to go on record as vigorously endorsing the program of x-raying all persons coming into our hospitals in Minnesota. We suggest that we reaffirm our position with regard to this program and seek the help of the Minnesota Tuberculosis and Health Association in continuing to encourage the program in all of the counties in the state. Nearly 53 per cent of the hospitals now take routine x-rays of all admissions. It is estimated that 81 per cent of Minnesota's hospital patients now receive chest x-ray examinations.

We suggest a speakers' bureau, composed of doctors who are definitely interested in the field of tuberculosis, who would stand ready to attend county meetings, hospital staff meetings, wherever there was a need for a good selling job on routine x-ray of hospital admissions. Members of a speakers' bureau could also be available to speak at various meetings throughout the state. The Minnesota Tuberculosis and Health Association is capable of arranging meetings and they would provide an excellent avenue of education and extremely effective method of reaching the people as to the current hazards of tuberculosis and ever dangerous aspects of the disease.

Tuberculin Testing and X-Raying in Old Age and Nursing Homes

This committee recommends the continuance of this program and that it should be a rule of every old age home either to make a tuberculin test or x-ray examination of every old aged person on admission.

This program is important because we are finding more tuberculosis today in the older people and we are discovering too frequently that our older people are the source of contact for younger people. The increase in population of persons over sixty-five is becoming bigger and bigger every year. This means that the persons who are harboring tubercle bacilli are given a much longer span of years to spread the disease than formerly. It is imperative that we watch closely our older people and give them the advantage of our tests if we hope to properly protect those who associate with them.

Tuberculin Testing in Industrial Plants

Industrial employers are becoming more interested in the better health of their employes and the employer who includes in the physical examination of his employes the routine tuberculin test and x-ray is indeed following a wise course.

We strongly recommend that tuberculin testing and x-ray of the employes of industrial groups be endorsed by this committee.

Tuberculin Testing in the Doctor's Office

Encourage every family physician to routinely administer a tuberculin test to every patient coming into his office, following determination that the patient is not a reactor.

In case the patient is either a former reactor or a new reactor, the physician should be encouraged to follow through and see that the patient has an x-ray with proper interpretation.

It is the opinion of this subcommittee that there is perhaps no better way to stimulate the interest of the general practitioner in the value and importance of the tuberculin test than by his active participation in either a school, community-wide or county-wide tuberculin testing survey. When he actually sees up to 25 per cent of the persons in his community or county reacting to the test he becomes impressed with the prevalence of infection and the potential active cases of the future for it is estimated that 5 per cent of all reactors to the tuberculin test will sometime break down with active tuberculosis.

Summary

In analyzing the productive opportunities for case-finding, this committee sets forth the following
(Continued on Page A-53)

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

"MEDICARE" IS BIG BUSINESS IN MINNESOTA

When the Dependents' Medical Care Program began in December, 1956, most people thought it would be a limited program. Both government and state medical association officials believed relatively few doctors and patients would be involved in Minnesota.

It is now obvious that all hands were wrong. When contractors and auditors began to check up in preparation for winding up accounts at the end of the fiscal year, the following figures were uncovered:

The total number of claims processed through the Minnesota State Medical Association through July 31, 1957, was 1,553. The total amount of money paid to physicians was \$115,277.55.

The number of claims received daily in the State Office averages twenty-nine per day and is increasing steadily. The operation is obviously becoming a major activity of the Association.

Red Tape Inevitable

The observation that Medicare will prove to be a dry run for other government medical programs is frequently made, and with obvious justification. It should be said, however, that army officials in the Office of the Surgeon General have been co-operative and understanding, and the delays and red tape associated with administration of the program have been only what is inevitable in any government undertaking.

Recent delays in payments have not been the fault of the officials in charge since Medicare had to wait for funds along with a good many other government operations while Congress argued about other things.

Figures Are Staggering

In that connection, some interesting figures on the subject of government medical care were assembled in a recent *Journal* of the Michigan State Medical Society.

It appears that a staggering total of 33,569,000 persons are eligible for full or part-time medical care at government expense right now. That num-

ber includes the 5,200,000 military personnel and their families who were voted into Medicare last year, plus 22,599,000 veterans, 5,100,000 recipients of public assistance, 370,000 Indians and Alaskan and 300,000 other dependents of the U. S. Public Health Service.

The number increases each year and so does the demand. America is the only nation in the world which has developed a workable alternative to compulsory government insurance to meet that demand. The importance of strengthening and extending the typically American answer to government medicine becomes urgent in the light of the above figures.

FEES INCREASED AND AUTHORIZATION TIME EXTENDED IN HOME-TOWN CARE PROGRAM

Changes in procedure have just been announced with respect to both fees and to authorizations required in the Home-Town Care program for veterans.

Authorization for as long as a year in advance can now be made in the case of patients in need of long-term care. If conditions warrant and the co-operation of the attending physician is assured, monthly re-authorization can be eliminated in these cases. The physician may bill the Veterans Administration each month for services rendered, but he is required to report on these long-term cases only every three months.

A new fee schedule has been announced also by the Central Office of the Veterans Administration. Maximums have been increased in accordance with this schedule in a considerable number of instances.

At the same time, VA medical officers have been instructed that fees shall not exceed those usually paid for similar services in the community. The increases are applicable all over the country, however, regardless of whether or not an intermediary agreement exists between medical associations and the Veterans Administration.

Minnesota's contract expired in 1954 and the Minnesota State Medical Association did not enter into the altered type of contract offered at that time. Under the present arrangement in

Minnesota, VA officials contract directly with physicians who are willing to provide home-town care.

TAX RELIEF FOR CANADIAN SELF-EMPLOYED

Of interest in connection with continuing discussions of the Social Security question for physicians is recent news about Canada's solution to the problem.

According to the general secretary of the Canadian Medical Association, the Canadian parliament has adopted an amendment to the Canadian Income Tax Act which is comparable to the Jenkins-Keogh bill which the American Medical Association has been supporting. The Canadian limits of deferment are said to be 10 per cent of income, or \$2,500 a year, whichever is the lesser. Under the Jenkins-Keogh bill, the limits would be 10 per cent of earned income or \$5,000 instead of the \$2,500 in the Canadian law.

It is interesting to note that Britain, stronghold of "cradle-to-grave" security was the first major nation in the world to adopt comparable legislation for the self-employed.

Hearings on the Jenkins-Keogh bill and other tax measures have now been scheduled for January by Chairman Jere Cooper of the House Ways and Means Committee.

MAJOR PROTECTION POLICIES ARE POPULAR

Major Medical Expense Insurance is a recent development among current programs for protection against major misfortunes. Its rapid public acceptance should be highly encouraging to all who are interested in extension of voluntary prepayment plans.

The first policies were sold in 1949, and when the reports for 1956 are all in, it is expected by insurance experts that more than ten million people in the United States will be shown to be covered.

Included in the ten million are 72 per cent of members of the Minnesota State Medical Association who signed up during the charter enrollment period for the Association's new Group Major Hospitalization Program, initiated with approval of Council and House of Delegates in May.

This ready acceptance by doctors of this type of group protection not only insured the successful launching of another insurance program under

State Association auspices, it is also good public evidence of the worth of voluntary prepayment plans as a cushion against medical and hospital expenses in case of illness.

If the doctors, who know best how costs can mount, like group plans for protecting themselves and their families, their patients are likely to be even more easily persuaded.

LEGISLATIVE REVIEW, 1957

Below is an interesting brief summary of what state law-makers did about health and medical matters at the 1957 session of the Legislature. It is borrowed from *Conference Call* published by the Minnesota Public Health Conference and compiled for public health workers, but it concerns enactments of equal interest to physicians. Many of the actions listed may have escaped notice at the time of passage.

Aging

The appointment of a special assistant on aging in the unclassified service of the Department of Public Welfare was authorized and county welfare boards may employ county service co-ordinators and "to further the well-being of the aging" may appoint citizens' advisory committees. (C. 762).

Children

An advisory board consisting of twelve members was created to aid in "formulating policies and encouraging programs" for handicapped, gifted, and exceptional children. (C. 778).

The Minnesota Residential Treatment Center for emotionally disturbed and psychotic children was authorized. It is to be located within 25 miles of the Minneapolis campus of the University and be under the management of the commissioner of welfare. (C. 957).

Civil Defense

The State Board of Health was authorized to procure and store blood typing serums, donor and recipient sets, and blood containers to collect citrated whole human blood for transfusion purposes, and to store in hospitals, etc., a year's supply to facilitate collection and use; \$50,000 was appropriated. (C. 653).

County Nursing Service

Cass County was authorized to levy two mills for public health nursing. (C. 213).

General Health and Safety

Authority was given to the State Board of Health to conduct programs "in home safety, designed to prevent accidents and fatalities resulting therefrom," and for the purpose may co-operate with local boards of health, the Minnesota Safety Council and other interested groups. (C. 290).

A law providing for a fire safety code was passed, which will enable the state fire marshal to adopt and enforce standards for fire protection in hospitals, nursing homes, rest homes, board and care homes, as defined by the State Board of Health, and in schools, hotels, et cetera. (C. 723).

The State Board of Health also was authorized to adopt and enforce reasonable regulations for the control of atmospheric pollution and ionizing radiation. (C. 361).

Hospitals

A law of state-wide application was enacted to permit hospital districts to be formed of towns, villages, and cities within any county of the state. (C. 640).

Proceedings undertaken by Rice County under the hospital district law applicable to that county (C. 400, Laws 1955) were legalized. (C. 3).

Where a town with a village therein has a population of from 2,000 to 10,000 with a 17-mill levy producing \$1,000 per governmental section, it may incur indebtedness not to exceed \$500,000 and may apply for federal aid for hospital construction. (C. 122).

Any city, village or town, the valuation of which consists of more than 25 per cent iron ore, may lease any community or municipal hospital to any incorporated, non-profit association. (C. 116).

Joint hospital facilities were authorized for Ramsey County and St. Paul. (C. 938).

The creation of a hospital district was authorized in any county where the normal capacity of all public and private general hospitals licensed by the State Health Department is not less than sixty-three nor more than seventy beds. (C. 315).

Creation of a hospital district was authorized in a county having over 14,000 and less than 15,000 people and over thirty and less than fifty-six townships. (C. 539).

Members of a county hospital board who are not members of the county board may receive 7½ cents per mile for traveling to meetings. (C. 83).

Local Health

The 1947 County Board of Health Act which authorized a county to form a county health department or to join with others in forming a multi-county health department was amended to provide for an increase in the levy from one to two mills for support of such a department. (C. 470).

Municipalities were forbidden to license the service of meals at fairs conducted by county agricultural societies. (C. 59).

Marriage Reporting

On January 1, 1958, clerks of court will begin reporting to the State Board of Health's Vital Statistics Section data on marriage licenses in order to permit the establishment of a state-wide index and the collection of marriage statistics. (C. 886).

Mental Health

The interstate compact on mental health was enacted into law. It authorized the Commissioner of the Department of Public Welfare to make interstate agreements concerning the institutionalization of mentally ill in and the responsibilities of party states. (C. 326).

Nursing Homes

The only bill of the three-bill package on nursing homes to pass was the one stating that by a majority instead of a unanimous vote, a county board may establish a nursing home. (C. 865). Those which failed were: The \$2,000,000 nursing home construction subsidy bill, and the bill authorizing towns, villages, and cities to construct and operate nursing homes.

Sanitary Disposal Authority

Two or more villages or cities of the second, third, or fourth class, situated within 25 miles of the city hall of a city of the first class with a population in excess of 500,000 may create a sanitary disposal authority. Such authority may provide for the sanitary collection of garbage and refuse. (C. 450).

Tuberculosis

A County Sanatorium Commission, with the consent of the Commissioner of the Department of Public Welfare, the State Board of Health, and the county board, may employ a tuberculosis control officer who shall be a licensed physician and

have the powers and duties of health officers and boards of health relative to tuberculosis. (C. 302). The use of county sanatoriums "for the care of persons afflicted with a malady, deformity, or ailment other than tuberculosis . . . which can properly be remedied by hospital care, service, and treatment, excluding nursing home patients" was authorized. (C. 691).

The court may issue a warrant committing a person to a tuberculosis sanatorium or public hospital where he shall remain until he is discharged and is not contagious. The court may, with the consent of the commissioner of public welfare, order the patient confined at the tuberculosis unit at Anoka State Hospital until such time as the commissioner determines that he may be safely cared for at the sanatorium or hospital named in the court's findings. Also, if any patient willingly leaves the sanatorium or hospital without consent, the court, upon request of the superintendent or chief medical officer, and with the consent of the commissioner of public welfare, may amend its order and confine such person to the tuberculosis unit at Anoka State Hospital. (C. 317).

Where a person has resided in Minnesota throughout the year preceding commitment, but not in any one county during such time, the Commissioner of Public Welfare shall pay to the county sanatorium where the person is received, the same fee that is received for non-residents. The fee shall be paid out of funds appropriated for the maintenance of county sanatoria. (C. 654).

Medical laboratory employes of the State Board of Health and nurses contracting tuberculosis in the course of their employment were placed under the special workmen's compensation provisions which allow payment of medical care and compensation at two-thirds of salary. (C. 31).

Welfare

The Commissioner of the Department of Public Welfare was authorized to make grants to any city, county, town, or village, or combination of them, or to non-profit corporations in assisting with the establishment and operation of community service mental health programs to provide (a) preventive, (b) educational, (c) consultative, (d) out-patient treatment, and (e) rehabilitation services. Grants made for mental health services, whether provided by a local facility or through contract with

other public or private agencies, shall not exceed 50 per cent of the expenditures nor 50 cents per capita for the area served. To come within the act, communities shall establish nine-member community mental health boards. (C. 392).

CORONARY INSUFFICIENCY DISEASE

(Continued from Page 695)

ability to reproduce the pain by pressure over tender points or by torsion of the thorax is of great help in convincing and reassuring the patient. The observation of the patient's gestures enables one to decide more easily what maneuver to use to reproduce the pain. A somewhat similar point has been made by Harrison.⁴

Summary

Patients with coronary insufficiency pain frequently use gestures to describe their pain which are quite characteristic and in contrast to gestures used by people with noncardiac chest pain. The placement of the flattened palm and fingers over the midsternum and slight movement horizontally across the chest were the most commonly used maneuvers. These and other gestures are discussed.

For the practitioner who sees many patients per day, perhaps at home under unfavorable circumstances for prolonged questioning or detailed examination, or who may see patients in the office under hurried circumstances, the observation of these coronary insufficiency gestures may provide some guide to the type of investigation to pursue.

History of Medicine in Minnesota

NOTES ON THE MEDICAL HISTORY OF BECKER COUNTY

G. G. HAIGHT, M.D.

Audubon, Minnesota

Becker County, named in honor of General George L. Becker, had been a part of Stearns County and later of Douglas County, but, in 1858, it was established as a separate county by an act of the legislature.

The surface materials of this territory were deposited during the glacier period and are known as a drift formation. The soil in the eastern and central parts is made up of sand and gravel with a small amount of clay, while the western part is mainly clay with isolated areas of sand and gravel.

Becker County contains 296 lakes with areas varying from 40 acres to more than 7,000 acres, the largest being Cormorant Lake, and many ponds of 5 to 40 acres.

The highest point of land in this region of the state, 1,750 feet above sea level, is part of a dividing ridge in the northeastern corner of Becker County. Water from the eastern slope of this ridge drains into the Mississippi River and eventually into the Gulf of Mexico. Water from the western slope drains into the Red River and eventually into the Arctic. Both of these rivers begin their flow in a direction opposite to their general course and final destination.

Four hundred and sixty species of trees and natural flowers have been found. Pine and fir, from which much lumber has been taken, were found in the eastern sandy part, while, oak, ash, elm, and poplar abound in the western part. Medicinal plants, such as ginseng, snake root, buck root, kidney wort, and poisonous plants including poison hemlock and poison oak and sumac, which are poisonous externally, originally existed. The state flower, the pink lady slipper, was also found in Becker County. One of the most important food plants to the early Indians was wild rice which is still harvested by them in this region today.

In olden times, most of the animals indigent to the United States, from the buffalo and moose to the mouse and the mole, were found in the county. There were also many fish such as pike, pickerel, bass, perch, tullibee, and sucker. As many as 262 different kinds of birds have been identified, including eighty-three water fowl and 179 land birds.

How was this country first peopled? Bancroft, the noted historian, expressed his belief that the Indians are of Mongolian descent. Be that as it may, it is unprofitable to speculate.

In 1825, the Sioux and the Chippewa tribes were feuding over the Northwest Territory, so the authorities at Washington convened a grand congress of Indians at Prairie du Chien, Wisconsin, under Governor Clark of Missouri and Governor Cass of Michigan. This congress established a boundary line between the Sioux and Chippewa. In Minnesota, this boundary line ran from Ottertail Lake north to the Buffalo River, down this river to the Red River. This placed most of Becker County in the Chippewa Territory. Later treaties ceded all land in the county to the United States government. In exchange, the Chippewas received part of White Earth Reservation, an area of land 36 miles square.

In 1802, the Northwest Fur Company had come to White Earth, which was then on the old Red River Road to Pembina and Ft. Garry, now Winnipeg. By the treaty of 1867, 700 of the Indians at Leech Lake were to be moved to the

White Earth Reservation. About 150 arrived on June 14, and that date is still celebrated every year. Machinery for a saw mill was moved here in 1868, and logs were sawed to get lumber to build a store and houses. Two hundred and forty acres of land were broken that summer. Paul Beaulieu was sent by the agent, B. J. Bassett, as overseer.

The first medical men to appear in Becker County were those assigned to the White Earth Indian Reservation by the United States government. **Dr. F. S. Boldle** came from Owatonna, Steele County, in 1865 after serving as surgeon in the U.S. Army. He was then appointed government physician for the Chippewas at White Earth. In 1878, he went to Grinnell, Iowa.

Dr. David Pyle, who had been a member of the state legislature from McLeod County in 1868, was appointed to White Earth in 1869. The following year, he settled on a claim in what is now Audubon Township. He was very helpful to the early settlers and was held in great esteem by them. He left the county in the early seventies.

Dr. Thornton Parker, who had graduated from the Royal University at Munich, was surgeon at White Earth for a time. He moved away in 1881.

In 1881, **Dr. C. N. Hewitt** reported the following diseases at White Earth, Leech Lake, and Red Lake: venereal, 171; diathetic, 564; tuberculosis, 424; parasitic, 183; respiratory tract, 639; eye, 347; and ear, 114.

The Reverend Joseph Gilfillan,* an Episcopal missionary who was born in Canada and died at White Earth, June 12, 1902, reported that there was severe smallpox during the winter of 1883. He constantly saw children clad only in cotton shirts, cotton leggings, and moccasins standing in the road in the cold, snowy weather, coughing violently from whooping cough. This missionary had come to White Earth to assist Reverend Johnson in mission work and became very much respected and loved by the Indians among whom he worked.

In 1901, Dr. Hewitt complained to Washington that a smallpox epidemic was being handled improperly at White Earth. **Dr. W. J. Stephenson**, agency physician, thought he had had all smallpox suppressed. He then found four cases and ordered more vaccine, saying he would vaccinate any Indian who had not had smallpox and would keep at it until all were immunized.

Dr. Charles Monroe Cannon was appointed physician in charge of the Reservation in 1889. He stayed there a little more than a year, until 1890, when he returned to Alden.

The first white woman to come to White Earth was Mrs. John Cook, the wife of the overseer of farming, who came from Wisconsin in the spring of 1870. In the spring of 1871, the Cooks moved to a new home and farm near Audubon where, a year afterwards, all the members of the family were cruelly murdered by Chippewa Indians. The site is now marked by a monument enclosed by a chain fence. Bobolink and Boanece were the principal actors in this tragedy. They were both arrested, but Boanece was released for lack of evidence. Bobolink was tried by a court of law at Detroit, where Doctors Pyle and Calkins were witnesses for the prosecution and Doctors Sully and Maltby were witnesses for the defense. After two hours of deliberation, the jury rendered the verdict of "guilty of murder in the first degree" and recommended the death penalty. While waiting in the St. Paul jail for the Governor to fix the date of the execution, Bobolink died.

Before leaving the history of the White Earth Reservation, we might cite what

*Jordan, Phillip D.: *The People's Health, the History of Public Health in Minnesota*. Minnesota Historical Society, 1953.

the first agency manager, Major J. B. Bassett, said regarding the treatment of the Indians by the government:

"My experience with the Indian Department shows to my mind the most incomprehensible absurdity that a civilized people ever attempted to impose upon an uncivilized race. To attempt to civilize a people and at the same time prevent them from adopting any of the arts or advantages of civilization is to my mind absolutely absurd and ridiculous."

The United States Government was anxious to open up the county to the northwest. To do this, they gave the North Pacific Railroad a land grant of every odd section, 20 miles each side of the center of the proposed road. The first exploratory expedition for the Northern Pacific went south of the present route, but on the return trip from the Missouri River, which had been found feasible to bridge, the explorers went north of the site of the town of Fargo and followed about the present route. The grading began at the eastern border of the county in mid-October, 1870, and advanced over the western border by mid-November, 1871. By December first, trains made regular trips to Oak Lake Cut, and they continued to do so on through the winter, but only two trains went on from there to Moorhead, for the road was blocked by snow and was not opened until mid-April although \$30,000 were spent in a vain attempt to keep it open by shoveling.

The first village was at Oak Lake, where the Northern Pacific was making the biggest cut from Duluth to the Missouri River. By the time the rails were laid, the population was 400, with four stores, two hotels, a dance hall, and many tents. The first political meeting in Becker County was held here, with Governor Austin the principal speaker. During the meeting, two dogs, one belonging to a settler and the other to a gambler, began to fight. Angered that his dog was getting the worst of the fight, the gambler went looking for the settler. By mistake, he hit the wrong man with his revolver leaving a mark which that man carried to his death.

In 1868, the first settlers at Oak Lake were so pleased with the land that they signed up without leaving their wagons. Henry Way, A. W. Sherman, and L. D. Sperry put up hay and returned to Battle Lake for the winter, but were back with their families the next spring.

On the first exploratory expedition to locate the Northern Pacific right-of-way, a Boston correspondent by the name of Charles Carlton Coffin accompanied the surveying crew. He was so taken with the land that he gave the name Park Region to this beautiful country. Bayard Taylor, a celebrated traveler, pictured the region as one of the most beautiful he had ever seen. On his return to Boston, Coffin lectured on the opportunities of this region. Meetings were held, and the New England Colony was formed to take advantage of the law that Congress had passed at the close of the Civil War giving to every soldier, sailor and marine, 160 acres of land which could be taken under the Homestead Act. Committees were appointed to visit the western lands. Some came via St. Cloud and then by wagon to Becker County. Some came via the lakes to Duluth, a town of 300, and then by railroad to Crow Wing and by wagon to Becker County. They purchased all the odd sections in Detroit township from the Northern Pacific. The articles of incorporation placed the affairs of the colony in the hands of one man, Colonel George H. Johnson of Boston, who was to act as trustee until his successor should be chosen. After several years, the whole of this valuable acquisition came into his hands. Some of the members lacked staying qualities for, by 1873, they began to scatter, their number dwindling down until of the 300 or more many had returned to their former homes. Perhaps the great grasshopper plagues which swept over Minnesota in 1871 and 1872 and again in 1874 and 1875 had something

to do with this. The grasshoppers were so numerous at this time that they obscured the sun at noon and stopped trains by making the rails so slippery that the trains could not move. During this time, the work that the settlers got from the railroad saved many of them from starvation.

In 1871, the county was organized politically. The governor appointed three commissioners and **Dr. David Pyle** was appointed county auditor. Without any buildings in which to hold meetings, the various county officials held forth at their places of business, mostly at Oak Lake and then at Lake Park and Detroit. The biggest scrap came over the site of the county seat. Audubon was favored at first, and Lake Park sided with the Audubon group, but in 1877, the general election decided that the county seat should be at Detroit. It was not until 1885 that a court house was ready for use.

The first doctor to come to Detroit was **Dr. Dexter Maltby**. He arrived in April, 1871. There were four tents, a frame store, and a log hotel. Dr. Maltby's practice that season was mainly among the employes of the railroad at Oak Lake. In the Civil War, he had been in the Union Army and studied medicine afterwards, receiving a certificate from the examining board in 1871. He was in Detroit about ten years.

Not many physicians located in Becker County in the 1870's. **Dr. C. A. Lampanius** was coroner in Audubon from 1874 to 1880. **Dr. John Froshaug** came to Lake Park in 1877. He was delegate to the Republican State Convention and later coroner. At the very end of the decade, **Dr. John Carman** came to Detroit. He became one of the most beloved physicians of the county and a real credit to the medical profession.

During the 1880's **Dr. Aretus K. Norton** came to Becker County, locating in Detroit. In the same decade, **Dr. Edward Hoit** arrived. He had homeopathic as well as regular medical training. At about the same time, **Dr. Emma K. Ogden** established herself in Detroit. **Dr. Niles R. H. Jewell** came to Lake Park in 1886 or before. **Dr. Joseph G. Hodgkinson**, a graduate of the St. Paul Medical College in 1886, located immediately in Detroit.

A number of these physicians are no longer listed after the early nineties, but a fair number arrived during the last decade of the 19th century. Among them we find **Dr. W. M. Morton**, who was listed in Detroit in 1893. **Dr. S. S. Jones** was coroner of Frazee from 1897 to 1899, and **Dr. Thomas Howell** was in this little town in 1898 when it had only 279 inhabitants. In Lake Park, which was considerably larger than Frazee, **Dr. H. E. Armstrong** practiced in 1896, **Dr. Roland T. Gilmore** in 1898, and **Dr. M. B. Smith** in 1900. **Dr. O. K. Winberg**, a Norwegian physician who came to Lake Park in about 1893, was later one of the organizers of the movement that resulted in the establishment of Sand Beach Sanatorium, and for many years he was one of its directors. Another physician who is important in the Medical History of Becker County, was **Dr. Leonard Case Weeks**. He came to Detroit in 1896. He held a number of public offices, medical as well as non-medical, giving services in a difficult country practice for a quarter of a century. This strenuous work took its toll, and he passed away at the early age of fifty-seven years.

Biographical Sketches

Dr. Henry Edward Armstrong is listed in Lake Park in 1896 and 1898. He received his medical education in Canada, graduating from Trinity Medical College, Toronto, in 1894. He was licensed in Ontario in the same year and on October 8 of the following year in Minnesota. It probably was in this year, 1895, that he came to Lake Park. At that time, he and **Dr. O. K. Winberg** were the only

physicians in Lake Park. In 1897, he was licensed to practice in North Dakota and, in 1898, in Montana, locating in Billings. Dr. Armstrong became well established in Billings, becoming a leading diagnostician. At the time of his death, he was the dean of eastern Montana physicians. He died suddenly at Billings on January 10, 1934, from a heart attack. He was sixty-six years old. Not much is known about his stay in Becker County, no doubt due to the shortness of his stay there. It seems that he did not actually locate in North Dakota.

Dr. Ed. Barton came to Frazee in 1901 when Dr. Benson decided not to return to his practice, which had been handled in the meantime by Dr. E. Carman. The Nichel's-Chisholm Lumber Company had mills at Frazee and hired many lumbermen to run the logs down the river to the mills. To take care of these men, Dr. Barton built a hospital which he continued to operate after the mills had cleared the land and moved west to Washington.

He was much interested in baseball and with the help of the lumber company, always put a good team in the field. He held many offices in the city and in the Clay-Becker Medical Society. In later life, he moved to Minneapolis where he practiced for a time before his death.

A **Dr. Benson** apparently was in Frazee in the late 90's. It seems he left with the intention of returning, leaving Dr. E. Carman in charge of his practice. By 1901, it was certain that he would not come back and Dr. E. Barton took his place.

Dr. F. S. Boldle was a surgeon in the U. S. Army during the Civil War and came to Owatonna, Steele County, in 1865. He was appointed Government Physician for the Chippewa Indians at White Earth Reservation. In 1878, he went to Grinnell, Iowa, and later moved to Oakland, California. He was a member of the Minnesota State Medical Society.

Dr. Charles Monroe Cannon* was born in Wisconsin, August 18, 1861, and had his preliminary education in the public schools of Cherokee, Iowa, and Drake University, Des Moines, Iowa. He received his medical education at Bennett Medical College, Chicago, from which he was graduated in 1888. At first he practiced in Alden, Freeborn County. He was supposedly located in Alden in 1887. If this is correct, he must have started to practice before his graduation and returned there after he finished medical school. He bought the residence of Dr. G. A. Stevenson and there may have been some partnership arrangement at first.

He was appointed physician in charge of the White Earth Reservation in 1889 under Congressman Dunnell. After little more than one year, in May, 1890, he returned to Alden and stayed there until February, 1893, when he moved to St. Paul. There he practiced until his death in 1923. From 1892 to 1895, he was a member of the Minnesota State Board of Medical Examiners. He was elected to membership in the Ramsey County Medical Society and the Wisconsin State Medical Association in 1895. He also was a member of the American Medical Association.

Dr. Cannon married Edith M. Morey, a member of an Alden pioneer family. They had two daughters and one son. He was a highly respected citizen.

*Much of this information is taken from the medical history of Freeborn County, by Dr. Andrew Gullixson, MINNESOTA MEDICINE, January, 1949.

(To be continued in the January issue)

NO KNOWN CONTRAINDICATIONS

ROLICTON®

permits high dosage,
more effective diuresis in more patients

The low incidence of side action with Rolicton (brand of amisometradine) permits high dosage, extending the range of effective diuresis to a greater number of patients than was previously possible.

Laboratory studies demonstrate that Searle's new oral diuretic, Rolicton, causes positive diuresis with an essentially balanced excretion of water, sodium and chlorides.

Settel¹ studied the effect of Rolicton in forty-seven patients and found no serious side effects. Assali, who observed the action of Rolicton in five patients with severe toxemia of pregnancy, states² that side actions are essentially non-existent. Side actions of such low incidence, together with its diuretic efficacy, suggest a high order of usefulness for Rolicton.

One tablet of Rolicton, b.i.d., is usually adequate to maintain patients free of edema after the first day's dosage of four tablets. Some patients respond well to one tablet daily. G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

PRIZE ESSAY CONTEST, AMERICAN COLLEGE OF CHEST PHYSICIANS

The American College of Chest Physicians is offering three cash awards of \$500, \$300, and \$200 each to winners of the 1958 prize essay contest, which is open to *undergraduate* medical students throughout the world. Essays may be written on any phase of the diagnosis and treatment of chest diseases, including the heart or lungs. The contest closes April 15, 1958. Further information may be obtained from the American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

VAN METER PRIZE AWARD

The American Goiter Association again offers the Van Meter Prize Award of \$300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The essays may cover either clinical or research investigations, should not exceed 3,000 words in length, and must be presented in English. Duplicate typewritten copies, double spaced, should be sent to the secretary, Dr. John C. McClinck, 149½ Washington Avenue, Albany 10, New York, not later than February 1, 1958.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, are as follows:

November 4-9	Cardiovascular Radiology for Specialists
November 18-20	Physical Medicine for Specialists
December 5-7	Fractures for General Physicians
January 6-11	Ophthalmology for Specialists
January 9-11	The Newer Drugs in General Practice

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

KENNY FOUNDATION SCHOLARSHIPS

The Sister Elizabeth Kenny Foundation announces a continuance of its postdoctoral scholarships to promote work in the field of neuromuscular diseases. These scholarships are designed for scientists at or near the end of their fellowship training in either basic or clinical fields concerned with the broad problem of neuromuscular diseases.

Kenny Foundation Scholars will be appointed annually. Each grant provides a stipend of from \$5000 to \$7000 a year for a five-year period, depending upon the

MEETINGS AND ANNOUNCEMENTS

olar's qualifications. Candidates from medical schools in the United States and Canada are eligible.

Inquiries concerning details should be sent without delay to: Dr. E. J. Huenekens, Medical Director, Sister Elizabeth Kenny Foundation, 2400 Foshay Tower, Minneapolis 2, Minnesota.

UNIVERSITY COURSE ON ADVANCED ORAL PATHOLOGY

The Medical and Dental Faculties of the University of Minnesota will present a course in "Advanced Oral Pathology" during the week of April 28 through May 1958. Both lectures and pathologic slide study will be included. The subjects covered will be: neoplastic and non-neoplastic diseases of the salivary glands, neoplasms of dental origin, bone pathology, soft tissue neoplasms, dermatologic pathology, diseases of the lymphoid system, and oral roentgenographic evidences of systemic disease.

The faculty will include Dr. Robert Lukes, Armed Forces Institute of Pathology; Drs. D. C. Dahlin and Edward Stafne of the Mayo Clinic; Dr. Robert Goltz of the Medical School, University of Minnesota; and Drs. Anand Chaudhry and Robert J. Gorlin of the School of Dentistry, University of Minnesota.

The tuition fee will be \$50, and an additional \$50 will be charged if room and board at the Center for

Continuation Studies are desired. Further information may be obtained from Dr. Robert J. Gorlin, Chairman, Division of Oral Pathology, School of Dentistry, University of Minnesota, Minneapolis, Minnesota.

OMAHA MID-WEST CLINICAL SOCIETY

Twelve guest speakers of national repute will be on the program of the twenty-fifth annual session of the Omaha Mid-West Clinical Society, November 4-7, 1957, at the Sheraton-Fontenelle Hotel in Omaha. Outstanding speakers include: Kenneth E. Appel, M.D., Chairman, Department of Psychiatry, University of Pennsylvania School of Medicine; Alvan L. Barach, M.D., Clinical Professor of Medicine, College of Physicians and Surgeons, Columbia University; Clyde G. Culbertson, M.D., Director, Biological Research Division, Lilly Research Laboratories; James G. Hughes, M.D., Professor of Pediatrics, University of Tennessee College of Medicine; Victor F. Marshall, M.D., Associate Professor of Clinical Surgery and Urology, Cornell University Medical College; John H. Moe, M.D., Clinical Professor and Director, Division of Orthopedic Surgery, University of Minnesota Medical School; Carl A. Moyer, M.D., Professor of Surgery and Head of Department, Washington University School of Medicine; G. O'Neil Proud, M.D., Professor and Chairman of the Department of Otorhinolaryngology, University of Kansas School of Medicine; H. R. Reichman, M.D., Assistant Clinical Professor of Surgery, University of Utah College of

Medicine; Herbert E. Schmitz, M.D., Professor and Chairman, Department of Obstetrics and Gynecology, Stritch School of Medicine, Loyola University; Colonel John P. Stapp, M.D., Chief, Aero-Medical Field Laboratory, Holloman Air Force Base, New Mexico; and Er. E. Wollaeger, M.D., Associate Professor of Medicine, University of Minnesota Graduate Medical School.

Four full days of postgraduate study are offered at this meeting, which have been approved for Category credit by the American Academy of General Practice. This Silver Jubilee session of the Society will include four panel discussions on Cesarean Section, Pelvic Injuries, Problems of Adolescence, and Clinical Use and Abuse of Steroids.

POSTGRADUATE COURSES

New York University-Bellevue Medical Center Postgraduate Medical School offers the following postgraduate courses to be given or started during the month of November, 1957:

Department of Medicine

Problems in Clinical Medicine.—A part-time course 9 a.m. to 12 m., Fridays, November 1 through April 25. Under the direction of Dr. Jack Nelson. Tuition \$75.00.

Fundamentals of Clinical Electrocardiographic Interpretation.—A part-time course of sixteen sessions, 7 to 9 p.m., Wednesdays, November 6 through March 5. Under the direction of Dr. J. Marion Bryant. Tuition \$50.00.

Arthritis and Allied Rheumatic Disorders.—A full-time course, November 11 through 15. Under the direction of Dr. Edward F. Hartung. Tuition \$85.00.

Electrocardiography.—A full-time course, November 11 through 15. Under the direction of Dr. J. Scott Butterworth. Tuition \$85.00.

This course is repeated, March 17 through 21, 1958.

Hematology.—A full-time course, November 11 through 15. Under the direction of Dr. Leo Weiner. Tuition \$85.00.

Diabetes Mellitus, Hyperinsulinism, and Hypoglycemia.—A full-time course, November 11 through 13. Under the direction of Dr. Benjamin I. Ashe. Tuition \$40.00.

Peripheral Vascular Diseases.—A full-time course, November 18 through 22. Under the direction of Dr. A. Wilbur Duryee. Tuition \$55.00.

Department of Obstetrics and Gynecology

Culdoscopy.—The course consists of three two-hour periods, 1 to 3 p.m., Monday, Wednesday, and Friday, November 25 through 29. Under the direction of Dr. Wayne H. Decker. Tuition \$55.00.

This course is repeated January 27 through 31, and April 28 through May 2, 1958.

Department of Ophthalmology

Ophthalmoscopy.—A part-time course, 9 a.m. to 12 m., November 4 through 8. Under the direction of Dr. George N. Wise. Tuition \$55.00.

Department of Otorhinolaryngology

Endaural Surgery.—A full-time course, November 4 through 16. Under the direction of Professor John F. Daly. Tuition \$250.00.

This course is repeated, January 27 through February 7, 1958.

Department of Pediatrics

Review of Clinical Pediatrics.—A full-time course, November 18 through 23. Under the direction of Professor Adolph G. De Sanctis. Tuition \$55.00. This course is repeated, February 17 through 22, 1958.

Pediatric Endocrinology and Related Metabolism.—A four-day course, 9 a.m. to 4 p.m., November 11 through 14. Under the direction of Dr. Beatrice Bergman and Dr. Herbert S. Kupperman of the Department of Medicine. Tuition \$85.00.

The following postgraduate courses will be given or started during the month of December, 1957:

Department of Medicine

Gastroscopy and Flexible Tube Esophagoscopy.—A part-time course of three months' duration, 10:30 to 1:30 a.m., Mondays, Wednesdays and Fridays, December 2. Under the direction of Dr. Edwin Boros. Tuition \$300. This course is repeated March 3, 1958.

Recent Advances in the Diagnosis and Treatment of Poisonings.—A full-time course, December 2 through 4. Under the direction of Dr. Abraham W. Freireich. Tuition \$60.00.

Department of Obstetrics and Gynecology

Infertility.—A full-time course, December 2 through 4. Tuition \$45.00.

Department of Ophthalmology

Surgery of the Cornea.—A full-time course, December 2 through 6. Under the direction of Dr. Ramon Casoviejo. Tuition \$200.00.

Department of Otorhinolaryngology

Endoscopy: Bronchoesophagology and Laryngology.—A full-time course, December 2 through 14. Under the direction of Professor John F. Daly. Tuition \$200.00.

Department of Pediatrics

Pediatric Cardiology.—A full-time course, December 2 through 6. Under the direction of Dr. Martin M. Maliner. Tuition \$55.00.

In Memoriam

WALTER WALLACE COVELL

Dr. W. W. Covell, St. Peter physician and surgeon, died September 17, 1957. He was seventy-six years old.

Dr. Covell had been practicing physician and surgeon for fifty-one years, thirty-seven of which were spent in the St. Peter community.

He was a graduate of Barnes Medical College in St. Louis, Missouri, and did postgraduate work at Poly-Clinic in New York City, New York.

Dr. Covell served with the United States Armed Forces in World War I.

His memberships include the William R. Witty Post 37 of the American Legion, Nicollet Lodge No. 54 A.F. & A.M., St. Peter Chapter No. 22 Royal Arch Masons, Ivanhoe Commandery No. 31 Knights Templar of St. Peter, and Zuhrah Temple of Minneapolis. Dr. Covell also belonged to the Nicollet-Le Sueur County Medical Society and the Minnesota State Medical Association.

Surviving him are his wife, Loretta; a son, Wallace; a daughter, Mrs. James Weisgerber; four grandchildren, Melanie and Kathy Covell, Mary and Ann Weisgerber; and two brothers, Rev. H. E. Covell of St. Petersburg, Florida, and Mr. Orson Covell of North Platte, Nebraska.

GERALD DIORA GUILBERT

Dr. Gerald D. Guilbert, a tuberculosis specialist at Fort Snelling Veterans Administration Hospital, died August 23, 1957. He was sixty-one years old.

Dr. Guilbert was graduated from the University of Minnesota School of Medicine in 1927. He served at VA hospitals in Tucson, Arizona; Asheville, North Carolina; Fort Bayard, New Mexico; Livermore, California; Milwaukee, Wisconsin; Kerrville, Texas; and Waukesha, Wisconsin.

His memberships include Acacia, Phi Beta Pi, American Trudeau Society, American College of Chest Physicians, and University Masonic Lodge 316.

Dr. Guilbert also belonged to Camp Release County Medical Society, Minnesota State Medical Association and American Medical Association.

Surviving him are his wife, Cornelia; a daughter, Mrs. George Eckstein, Santa Monica, California; a brother, Oliver, Gila Bend, Arizona; and a sister, Mrs. Alan Hardy, Escondido, California.

HAROLD IRVING LILLIE

Harold I. Lillie, former staff member of the Mayo Clinic and well-known specialist in diseases of the ear, nose and throat, died August 27, 1957. He was sixty-nine years old.

A native of Grand Haven, Michigan, Dr. Lillie re-

ceived his medical education at the University of Michigan, from which he graduated in 1912. He took his postgraduate work at the University of Minnesota Hospitals.

In 1917, Dr. Lillie joined the staff of the Mayo Clinic and remained there until he retired in 1953. He was president of the American Rhinological, Laryngological and Otological Society in 1939, and of the American Laryngological Society in 1945.

Dr. Lillie was also a member of the Southern Minnesota Medical Association, the Minnesota State Medical Association, Minnesota Academy of Ophthalmology and Otolaryngology, American Otological Society, American Academy of Ophthalmology and Otolaryngology, American Alumni Association of the Mayo Foundation, American Medical Association, Alpha Omega Alpha, medical honor society, Sigma Xi and Phi Beta Pi, professional medical fraternity. He was a life member of the University of Michigan Union and a fellow of the American College of Surgeons and of the International College of Surgeons.

Surviving him are his wife, the former Oda Kittredge; a son, Dr. John C. Lillie, Mayo Clinic, Rochester; a daughter, Mrs. Thomas C. Wilder, Spokane, Washington; nine grandchildren, and a brother, Hugh E. Lillie, Grand Haven, Michigan.

ROBERT FULLER MEARS

Dr. Robert F. Mears, a Northfield, Minnesota, physician, choked to death while on a cruising barge near Cannon Falls, Minnesota, August 26, 1957. He was forty-six years old.

Dr. Mears was born in St. Paul and obtained his medical education at the University of Minnesota. He interned at Minneapolis General Hospital before starting his practice in Northfield in 1940.

He was a member of the staff of Northfield City Hospital, Rotary Club, Masons, I.O.O.F., Rice County Public Health Nursing Board, Rice County Medical Society, Southern Minnesota Medical Society, Minnesota State Medical Association and American Medical Association.

Dr. Mears was also a physician and surgeon for the Northfield Foundry and Machine Company and Campbell Cereal Company of Northfield, a deacon at the Congregational-Baptist Church, past president of the Junior Chamber of Commerce, past president of the Northfield Golf Club, and past director of the Red Cross Regional Blood Bank.

Survivors include his wife, Helen; one son, Robert, fifteen; a daughter, Barbara, fourteen; one sister, Mrs. Gertrude Ogden, Orinda, California; and five brothers, Norman B., William E., and Dr. Burtis J. of St. Paul, Minnesota; C. Plin of Keokuk, Iowa; and Dr. Hiram E. of Menlo Park, California.

IN MEMORIAM

MUEL SAMUELSON

Dr. Samuel Samuelson, Robbinsdale physician, was killed August 25, 1957, when his small plane crashed near Tofte, Minnesota. His two sons, Paul, eight, and Edna, seven, were also killed in the accident.

He was born in Milwaukee, Wisconsin, and obtained his medical education at the University of Minnesota. Dr. Samuelson was the founder of Victory Memorial Hospital, now North Memorial Hospital.

He was a member of Hennepin County Medical Society, Minnesota State Medical Association, and the American Medical Association.

Surviving Dr. Samuelson are his wife, Edna; three daughters, Mrs. Phyllis Peterson, Nancy and Janet, all of Minneapolis, Minnesota; one sister, Mrs. Anna Anderson, Chicago, Illinois, and a brother, Arnold Samuelson, Fort Worth, Texas.

ARTHUR CLARENCE STRACHAUER

Dr. Arthur C. Strachauer, retired physician and surgeon, died August 23, 1957, in Minneapolis, Minnesota, at the age of seventy-four.

Dr. Strachauer was born and raised in Minneapolis. He received his medical degree at the University of Minnesota and took graduate training at the University of Wisconsin. In 1911, he joined the surgery staff of the University of Minnesota as an instructor, and in 1918 became head of the surgery department. He was also

director of the University Cancer Institute and co-founder of the Nicollet Clinic.

In 1930, he resigned to devote full time to private practice, in which he was chief surgeon for the Soo Line Railroad. He retired in 1943.

Dr. Strachauer was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, American Medical Association, Western Surgical Society, Delta Kappa Epsilon, Nu Sigma Nu, Minneapolis Club and the Lake Francis Gun Club.

He was also a fellow for life in the Minneapolis Art Institute and a life member of the Minnesota Historical Society.

Dr. Strachauer is survived by his wife; a son, Hermann, and four grandchildren.

SOFUS E. URBERG

Dr. Sofus E. Urberg, former chief of staff of St. Mary's and St. Luke's Hospitals in Duluth, Minnesota, died August 23, 1957. He was fifty-nine years old.

Born in Blair, Wisconsin, he attended Concordia College in Moorhead, Minnesota, and the University of Minnesota Medical School.

Dr. Urberg was very active in civic affairs and was a former director of the Department of Health of the Duluth Public Schools System. He was a member of the U. S. Army Reserve Corps, and was recalled to active duty with a National Guard unit in 1941. At that time, he served as a physician and interpreter for Norwegian ski troopers in Denver, Colorado.

He was past master of Ic Lodge No. 186 AF&AM, and physician for the Daughters of Norway.

Dr. Urberg is survived by his wife, Doris; two sisters, Mrs. Chester Anderson, Belgrade, Minnesota, and Mrs. O. G. Malmin, Minneapolis, Minnesota; two brothers, Rev. Conrad Urberg, Blair, Wisconsin, and Rev. Sig Urberg, Mahnommen, Minnesota.

ROSCOE CLAYTON WEBB

Dr. Roscoe C. Webb, chief surgeon of the Great Northern Railway, died August 16, 1957, in Minneapolis. He was sixty-seven years old.

Dr. Webb was a clinical associate professor of surgery at the University of Minnesota and a member of the staffs of Northwestern, Asbury Methodist, and Abbott hospitals.

A native of Amiret, Minnesota, he received his B.S. degree from the University of Minnesota and was a 1919 graduate of Johns Hopkins University School of Medicine.

Dr. Webb took his postgraduate work at Rockefeller Institute in New York and Harvard Medical School in Boston. He then spent two years in France and Germany with the American Expeditionary Forces. He became division surgeon of the Great Northern Railway in 1922 and was appointed chief surgeon in 1926.

A member of the Hennepin County Medical Society, Dr. Webb also belonged to the Minnesota State Medical Association, where he served as chairman of the Association's Committee on Fractures for many years, the American Medical Association, Johns Hopkins Surgical Society and was a presiding officer of the Minneapolis Academy of Medicine.

Survivors include his wife, Edith; two sons, Dr. Roscoe C., Jr., Los Angeles, California, and Dr. Robert I. Webb, Houston, Texas, and T. R. Webb, Paris, France.

Woman's Auxiliary

AUXILIARY LEADER DIES

Auxiliary women throughout the state are saddened by the death, August 19, 1957, of Margaret Scheman Wahlstrom, our beloved friend and leader. Margaret knew of illness for seven years before her death and accepted knowledge with courage and a determination to live every remaining day count. Her minister, the Reverend Howard Conn said, "She put a lot of living into everything she did, even into the last years of her illness. To the end, her courageous faith made her triumph over the ravages of disease."

She loved people and she wanted life to be better for people. She was a leader in many organizations, the Hennepin County Tuberculosis Association, the Red Cross, Minnesota rehabilitation work, the Y.W.C.A., Washburn Congregational Church, Washburn P.T.A., Carleton College Alumni Association, the University of Minnesota Faculty Club, and the Tourist Club. She organized the first cancer control program in Minneapolis and was a member of the state board of the American Cancer Society. And she was the first woman member of the United States committee of the World Medical Association.

Margaret's great work was done in furthering the needs of her husband's profession. She began in her county auxiliary and progressed through the state presidency to the highest office in the organization, the national presidency. Her year as state president was one of innovation: the publication of our first newsletter, health days, our first school of instruction, the relaying of medical information to lay organizations.

Her leadership qualities were exceptional, and she had the gift of inspiring enthusiasm in all who worked with her. We shall miss her radiant and lovable presence, her powerful voice, her sure judgments.

Surviving her are her husband, Dr. Harold F. Wahlstrom; her parents; two daughters, Mrs. Raymond Asp and Mrs. Joseph Husbands of Minneapolis; son, Harold, who is a student at Carleton College, and three grandchildren.

Her minister summed up her life when he said, "As a daughter, sister, wife, mother and friend, she was everything that could be desired."

Contributions for this column, including news and activities of state auxiliary societies and items of interest to members, may be sent to Mrs. A. B. Rosenfield, Woman's Auxiliary Editor, MINNESOTA MEDICINE, 2920 Franklin Boulevard, Minneapolis, Minnesota.

General Interest

"The Concept of Early Diagnosis in Cerebrovascular Disease" was the subject of a paper presented on September 10 at the Minnesota Society of Neurology and Psychiatry by **Dr. Robert G. Siekert**, Rochester.

* * *

Dr. John J. Regan, Minneapolis, presented a paper on "Psychiatry in a Multi-racial Community" at the regular meeting of the Minnesota Society of Neurology and Psychiatry, in Saint Paul, September 10.

* * *

Dr. Donald Olmanson, a 1956 graduate of the University of Minnesota Medical School, is now associated with his father, **Dr. E. G. Olmanson**, in the St. Peter Clinic in St. Peter. While in medical school, **Dr. Olmanson** did research work in rheumatic fever and other heart ailments.

* * *

Two physicians, who recently joined the staff of the East Range Clinic in Virginia, are **Dr. Isaac M. Prlina**, and **Dr. George B. Ewens**. **Dr. Prlina**, a specialist in urology, is a 1952 graduate of the University of Minnesota School of Medicine, and interned at the Long Beach, California, Veterans' Hospital. **Dr. Ewens**, a dermatologist, is the son of the late **Dr. Harry B. Ewens**, one of the founders of the East Range Clinic.

"JUNIOR! THAT'S NOT THE WAY THE APPLE'S SUPPOSED TO KEEP THE DOCTOR AWAY!"

Dr. James Pluth is now on the staff of the Mesa Clinic in Chisholm. **Dr. Pluth** was a graduate of University of Minnesota Medical School and has completed his internship at Cleveland City Hospital, Cleveland.

* * *

Col. J. R. Shaeffer, consultant on Medical Care Disaster at Walter Reed Army Institute of Research, spoke at a Mayo Clinic staff meeting on September 4 at the Mayo Civic Auditorium.

* * *

Dr. E. R. Chappell has recently joined the staff of the Stillwater Clinic as a specialist in surgery. **Dr. Chappell** is a graduate of the medical school of the University of Nebraska, and during the past four years has held a residency in general surgery at Louisville, Kentucky, General Hospital.

* * *

Dr. N. W. Barker, Mayo Clinic, Rochester, was among forty speakers at the Minnesota Heart Association fourth biennial symposium, "Peripheral Vascular Disease," held September 23-25 at the clinic. **Dr. Barker's** subject was "Anti-Coagulant Drugs in Therapy."

* * *

An open house in honor of **Dr. and Mrs. Richard Engwall** was held August 11 at Ivanhoe. **Dr. Engwall** was the winner of the first Rural Medical Scholarship awarded by the Minnesota State Medical Association, and also the first scholarship recipient to begin practice in the state of Minnesota. In accordance with the scholarship agreements, **Dr. Engwall** will practice in a rural community of 5,000 or less population in Minnesota for a period of at least five years. He has already opened his practice. Three other recipients are still at the University of Minnesota Medical School and a fourth will be chosen from applicants for the scholarship this fall.

* * *

NBC radio's "Monitor" recently featured **Dr. Robert N. Barr**, Secretary and Executive Officer of the Minnesota State Board of Health. **Dr. Barr** discussed Asian influenza.

* * *

Drs. D. C. Dahlin and **P. R. Lipscomb** attended the congress of the International Society of Orthopedic Surgeons in Barcelona, Spain, September 16 through 21.

* * *

Dr. John C. Wohlrabe, who has been in general practice at St. Clair, has set up a general medical practice at Mankato in the space formerly occupied by the late **Dr. H. J. Nilson**. **Dr. Wohlrabe** is the son of **Dr. C. F. Wohlrabe**, also of Mankato.

* * *

Dr. A. Hartwell Jewell, a graduate of Northwestern University School of Medicine, has recently joined the staff of the Austin Clinic, Austin, Minnesota, where his practice will be limited to surgery.

MINNESOTA BLUE SHIELD-BLUE CROSS

On November 1, 1957, Minnesota Blue Shield will complete its first ten years of operations as a voluntary, nonprofit, prepayment medical service plan. The Plan's progress, its acceptance by the public, and the amount of subscribers' benefits paid for doctors' services during this decade are worthy of review and consideration.

In slightly less than ten years of operation Blue Shield has increased benefits for over 200 items in the fee schedule and has added to the contract and fee schedule such services as consultation, emergency and intensive in-hospital medical care, electroshock therapy in psychiatric cases, and x-ray therapy and radioactive isotope services for certain diseases and conditions. A new, higher benefit, higher service income plan (Plan B) was made available to subscribers in March, 1954.

Enrollment-wise, Minnesota Blue Shield has grown from a plan of 6,500 participant subscribers at the end of 1947, to one of over 855,000 participant subscribers at the end of July, 1957, and currently ranks 12th among Blue Shield Plans of the United States.

From Minnesota Blue Shield's beginning through the month of July, 1957, approximately \$37,000,000 has been paid for physicians' services rendered to participant subscribers, and the Plan is currently providing benefits at the rate of over \$8,000,000 per year.

Each year the Blue Cross role in the health care of Minnesotans becomes increasingly important.

As of July 1, 1957, 1,127,226 Minnesotans were protected by Blue Cross coverage, a six per cent increase over the same period last year.

During the first seven months of 1957, 118,872 Blue Cross members used 722,512 days of hospital care, amounting to benefits totaling \$16,486,148. This was an increase of approximately \$3,000,000 over the same period of a year ago. During the same seven months period in 1952, Blue Cross payments totaled \$7,341,450.

The increase in enrollment during the last five years is further illustrated by the fact that as of July 31, 1952, there were 1,002,036 Minnesota Blue Cross participant subscribers, as compared to 1,127,226 in 1957.

During the period from July, 1952, to July, 1957, Blue Cross benefits available have been continually extended. The range of room and board allowances available have increased from \$9 to \$20.

The comprehensive Blue Cross contract providing full payment for semi-private rooms, and the average multi-bed charge of the hospital toward private room accommodations, has now been initiated by many large corporations in Minnesota. Under this same comprehensive contract, it is now possible to extend the number of days of hospital coverage to as many as 730.

During this five-year period from July, 1952, to 1957, several additional benefits have been added to Blue Cross contracts in keeping with the progress of new hospitalization-medical-surgical techniques.

One of the most recent increases in Blue Cross benefits was the extension of the number of days of coverage for tuberculosis, nervous and mental care from thirty days to the number of days covered under the basic contract which could amount to as many as 730 days in Blue Cross hospitals having proper facilities.

Book Reviews

Books listed here become the property of the Ramsey Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

MODERN PERINATAL CARE. Leslie V. Dill, M.F.A.C.S. Diplomate of the American Board of Obstetrics and Gynecology; Associate Clinical Professor of Obstetrics and Gynecology, Georgetown University School of Medicine; Consultant, Obstetrics and Gynecology, Army Medical School and Walter Reed General Hospital; Staff Member, Obstetrics and Gynecology, Providence Hospital, Washington, D. C. 464 pages. Illus. Price \$6.50. cloth. New York: Appleton-Century-Crofts, Inc., 1957.

VASCULAR SURGERY IN WORLD WAR II. Edited by D. C. Elkin and M. E. DeBakey, Medical Department, United States Army. 464 pages. Illus. Price \$4.25. Washington, D. C.: U. S. Printing Office, 1957.

To the surgeon in civilian practice, a case of acute vascular trauma is an uncommon incident, and thus the handling of hundreds of such limb- and life-endangering situations staggers his comprehension. In this volume, however, is compiled the mass experience of surgeons treating the vascular injuries during and after World War II. In an undramatic fashion, the authors present an exhaustive review of these observations.

Because of its extended statistical approach, this is a formidable book to read, but accompanying the analysis are many detailed references and explanations in the light of past and present knowledge which provide insight to the problems and their treatment.

The section on evaluation of vascular status is especially informative. Although much of this evaluation requires apparatus unavailable in most private hospitals, less complex methods of appraisal are also discussed and their application assayed in light of the authors' experience.

The discussion of arterial aneurysms and arterio-venous fistulae is particularly detailed, and the results have been carefully scrutinized by the authors, making this portion of the text a well-documented exploration of these two important problems. Sympathectomy as a preoperative and postoperative adjunct to therapy is also discussed at profitable length.

The text is sprinkled liberally with concise case reports illustrating some of the fundamental aspects of traumatic vascular repair and their complications.

This is not a text for casual browsing but will provide the student of this subject with basic knowledge. Drawn from a wide and, it is hoped, a unique experience.

NEW MEDICAL JOURNAL LAUNCHED

The American Rheumatism Association is pleased to announce the forthcoming publication of a new medical journal—*Arthritis and Rheumatism*, the official journal

of the American Rheumatism Association. Grune & Stratton, Inc., New York, publishers of the journals *Blood*, *Circulation*, *Circulation Research*, *Clinical Research Proceedings*, and *Metabolism*, have been chosen by the Association to publish this new journal which will appear bimonthly starting with the January-February issue of 1958. The Association's Publication Committee is composed of Drs. Richard H. Freyberg, William H. Kammerer, John Lansbury, Charles Ragan, and Charles L. Short. William S. Clark, M.D., has been chosen to serve as Editor, and the remainder of the Editorial Board will be announced subsequently.

The journal will cover the field of connective tissue disorders, in particular, rheumatoid arthritis, osteoarthritis, rheumatic fever, gout, the so-called "collagen diseases," and nonarticular rheumatism. In the choice of original articles, the Editorial Board hopes to achieve an optimal balance between papers relating to clinical experience and those which report pertinent developments in the basic sciences, such as immunology, biochemistry, pathology, and pharmacology. In addition to original and review articles, special departments will include news and notices, correspondence, editorials, progress reports, and book reviews. The contents of the journal should interest not only the specialist in rheumatic diseases, but also the internist, orthopedic surgeon, research worker, and all practitioners with a special interest in these diseases.

Replies to advertisements with key numbers should be mailed in care of MINNESOTA MEDICINE, 2642 University Avenue, Saint Paul 14, Minnesota.

OTOLARYNGOLOGIST WANTED—BOARD OR BOARD ELIGIBLE to join Clinic group of nineteen. Attractive salary leading to partnership. Unlimited potential. Completely modern EENT Department. Lake Michigan city of 45,000. Write Box 487, Sheboygan, Wisconsin.

GENERAL PRACTITIONERS—Two capable generalists needed for complete practice—expanding group serving three communities. New clinic facilities, new accredited hospitals. Specialist consultant available in group and expert radiologists and pathologists. Full hospital privileges immediately. Progressive area, finest schools and churches. Good recreational area, hunting and fishing. Salary open. Partnership possible within three years. Contact Mr. James Streitz, Manager, Mesaba Clinic, Hibbing, Minnesota.

WANTED—General Practitioner to take over suburban office in Twin Cities, either as independent or associate. Excellent practice established. Nothing to buy. Write E-601, care MINNESOTA MEDICINE.

WANTED—General Practitioner. Salary \$15,000 annually. Prefer married physician who has completed military obligations. No investment required. Partnership after three years. No office overhead. Salary is net. Must have car and pay for its upkeep, as well as own living expenses. Must have Minnesota license. Address E-598, care MINNESOTA MEDICINE.

WANTED—Junior Staff Physician interested in internal medicine and chest diseases for work in a well-equipped and well-staffed county tuberculosis sanatorium near Duluth. Salary and housing plus full maintenance. Immediate opening. Write R. W. Backus, M.D., Nopeming Sanatorium, Nopeming, Minnesota.

WANTED—Minnesota-licensed practitioner; unopposed; prosperous rural village, central Minnesota; completely equipped clinic; residence combination; open hospitals nearby; for sale or low rental with option to purchase; will introduce; leaving, postgraduate study; give personal data. Address E-600, care MINNESOTA MEDICINE.

WANTED—General Practitioner in Minnesota town of 750 in fine farming territory. Excellent office facilities. Now no other doctor in town. Address Belgrade Commercial Club, George Borgerding, President, Belgrade, Minnesota.

PLACEMENT SERVICE

The Minnesota State Medical Association maintains a Medical Placement Service for the benefit of physicians who are looking for locations and positions; also for communities, medical groups and physicians who are looking for licensed medical assistance. For information, write to the Minnesota State Medical Association, 496 Lowry Medical Arts Bldg., Saint Paul 2, Minnesota.

WANTED—General Practitioner for Lamberton, population 1,200, Redwood County, southwestern Minnesota. Practice unopposed; nothing to buy; free use of community-owned general and diagnostic equipment in eight-room, first-floor office; also patients charts and records of large active practice for nine years. Nearest hospital (new) 15 miles; nearest M.D. 1 mile. Leaving to specialize; will continue practice until replaced. Large modern rambler home available. Contact Dr. Morton Roan or T. E. Kuehl, Lamberton, Minnesota.

ASSISTANT WANTED—Very active general practice in Southern Minnesota. Partnership after one year. Address E-602, care MINNESOTA MEDICINE.

IMMEDIATE OPENING—For Internist, Obstetrician, Gynecologist, Ear, Nose, Throat Specialist and Pediatrician—Board or Board-eligible. Start at \$12,000 per year, option to join partnership. Call TUxedo 1-2623, or write Jack O. Kirkham, Manager, Oxbow Clinic, 9820 Lyndale Avenue South, Bloomington 20 Minnesota.

LOCATION DESIRED—Internist, age 33, Board certified, desires group practice or partnership in Twin Cities area. Military obligation completed. Address E-605, care MINNESOTA MEDICINE.

FOR SALE—Large, well-established general practice. Office well equipped, excellent location. Excellent hospital facilities. Center of fast-growing community iron mining, industrial. Heart of Arrowhead vacationland. Fishing, hunting, and all-year sports. Leaving December 1. Terms to suit. Will introduce. Write Dr. C. E. Sisler, 12 East Third Street, Grand Rapids Minnesota, or phone FAirview 6-6239.

FOR SALE—Office and equipment. Reasonable. New 32-bed hospital. Good credit rating community. Practice unopposed. Good fishing and hunting country. Reason for selling—illness. Address E-606, care MINNESOTA MEDICINE.

Problems in the Evaluation of Mitral Valvotomy

PAUL WINCHELL, M.D.
Minneapolis, Minnesota

DESPITE the fact that thousands of mitral valvotomies have been carried out, the value of this operation is unknown. Certain cardiovascular surgical procedures are obviously curative, such as the operations for coarctation of the aorta and patent ductus arteriosus. Other operations would appear to be curative although they must at the present time be considered as experimental, and in this group one would include closure of atrial septal defects and ventricular septal defects. Yet another group of cardiac surgical procedures can be considered as entirely experimental and as of yet undetermined value, perhaps one good example of this last group being surgery for aortic valvular disease. Mitral valvotomy seems not to fall clearly into any of the above classes, and evaluation of its present status is difficult.

In an attempt to assess properly mitral valvotomy, it would seem reasonable to consider the problem from several viewpoints. In order to understand the dynamics of mitral stenosis, it is first necessary to understand something about the dynamics of the lesser circulation in normal individuals. In evaluating any type of operation, it is obviously necessary to know something about the natural history of the disease when operation is not performed. Finally, one can consider the operative results currently available.

Some aspects of the dynamics of the normal pulmonary circulation are given in Figure 1. The most striking thing about this circuit is the relative lowness of the pressures involved, the normal mean pressure in the pulmonary artery being 15 millimeters of mercury, in the pulmonary capillary 10 millimeters of mercury, in the pulmonary vein 5 millimeters of mercury, and in the left atrium 0-5 millimeters of mercury. The gradient, or difference in pressures, between the pulmonary

artery and the pulmonary capillary is very small, being approximately 5 millimeters of mercury which is in marked contrast to the situation in the systemic circulation. It is apparent from the

Fig. 1. Pressure relationships in the normal pulmonary circulation.

schematic presentation of lesser circulation dynamics that obstruction at the level of the mitral valve will have an effect on the dynamics of the pulmonary circulation and of the left atrium.

Intimately involved in the entire problem are the small branches of the pulmonary artery where is found the major resistance to pulmonary blood flow. A normal small pulmonary artery magnified 250 times is shown in Figure 2. The ratio of the thickness of the artery wall to the lumen of the artery is very small. In other words, there is a relatively large opening through which the blood may pass and the artery wall is relatively thin.

The dynamics of mitral stenosis in its severe form are shown in Figure 3. The data given are derived from a series of patients studied at the University of Minnesota.¹ All of these individuals were functional Class III to IV at the time of their preoperative studies. It is apparent that several changes have occurred as contrasted with the normal circulation. The most striking change is a considerable elevation of the pressures in all segments of the lesser circulation. In this group

From the Department of Medicine, University of Minnesota Medical School, Minneapolis, Minnesota.

of six patients the pulmonary capillary pressure was found to be 34 millimeters of mercury, which is in excess of a three-fold elevation, while the pulmonary artery pressure was increased to a sim-

this group of patients the pulmonary capillary pressure of 34 millimeters of mercury closely approximates the colloid osmotic pressure of the blood plasma so that these particular patients

Fig. 2. Small pulmonary artery from a normal adult (X 250).

Fig. 3. Pressure relationships in the pulmonary circulation in far advanced mitral stenosis.

ilar degree, the mean value being 54 millimeters of mercury. In contrast to a gradient of 5 millimeters of mercury between the pulmonary artery and the pulmonary capillary in a normal individual, the gradient in this group of patients was approximately 20 millimeters of mercury, immediately raising a question as to the status of the small pulmonary arteries interposed between the main pulmonary artery and the pulmonary capillary which, as indicated above, are responsible for most of the resistance to blood flow through the pulmonary circuit. It is of interest that in

would appear to be on the very verge of pulmonary edema.

The fact that changes tending to increase resistance to blood flow do occur in the small pulmonary artery branches is documented by the section of a small pulmonary artery shown in Figure 4, taken from an individual dying of mitral stenosis. In comparison to the normal small pulmonary artery, there is an increase in the thickness of the wall of this vessel and a correspondingly marked diminution in the size of the lumen. The question comes up as to the effect of mitral valvotomy on such changes within the small pulmonary arteries and this question is not yet answered. Shown also in Figure 3 are the post-operative values for pulmonary artery and pulmonary capillary pressure in the same group of patients, at which time they were all classified as functional Class I and Class II. There has been a reduction in pressure, but a two-fold elevation of both pulmonary artery and pulmonary capillary pressure persists. In terms of systemic pressures this would represent a striking hypertension despite the fact that these operated patients had returned to a clinically normal functional status.

Attempts have been made to correlate the se-

verity of pulmonary hypertension with the severity of symptoms in mitral stenosis. The results of one of the earlier studies are given in Table I.² It would seem quite clear from these data that

Our knowledge of the natural history of mitral stenosis is far from complete. There are well documented instances of prolonged survival with mitral stenosis consistent with a relatively normal

Fig. 4. Small pulmonary artery from a fatal case of mitral stenosis (X 250).

TABLE I.² FUNCTIONAL STATUS VERSUS PULMONARY PRESSURE IN MITRAL STENOSIS

Number of Patients	Functional Status	Pressure Mm. Hg.
12	Normal	20/9
17	I-II	30/16
14	III-IV	69/34

in general the more severe the mitral stenosis, the higher is the pulmonary artery pressure. Using the relationship of resistance being equal to pressure divided by flow, it is permissible to calculate a value for the total resistance to blood flow through the pulmonary circuit, the value representing or reflecting to some degree changes within the small pulmonary artery branches. In Table II¹ are given values for mean pulmonary artery pressure and total pulmonary resistance as compared to normal individuals and it is quite apparent that in this group of class III and IV mitral stenosis patients a significant elevation of the total pulmonary resistance was present, the average value being almost eight times that of the normal circulation. With this information in mind it is useful to next consider the natural history of mitral stenosis.

TABLE II.¹ PULMONARY RESISTANCE IN MITRAL STENOSIS. CLASS III-IV

1.	66	1638
2.	52	855
3.	35	391
4.	37	854
5.	43	637
6.	92	3019
Average	54	1232
Normal	12	166

activity range. In Figure 5 are shown the postero-anterior and right lateral chest films of a fifty-six-year-old man in whom the diagnosis of mitral stenosis was first made in 1921. At this time, thirty-five years later, he continues to be active and is able to live an entirely normal life and to work full time as a teacher. He requires no medication. The findings at this time are typical of mitral stenosis. It would seem reasonable to assume that some, and possibly many, patients with mitral stenosis who are functional Class I or even functional Class II can live a nearly normal life. Certainly the clinical diagnosis of mitral stenosis is in itself not an indication for mitral valvotomy.

In contrast to the patient just mentioned, it

must be pointed out that people do die of mitral stenosis. In the group of fourteen Class III and IV mitral stenosis patients presented previously with pulmonary artery pressures in the neighbor-

embolization did occur in the absence of atrial fibrillation.³

What little is known about the natural history of mitral stenosis suggests that the milder form

Fig. 5. Postero-anterior and right lateral views of the chest from a case of mitral stenosis of thirty-five years' duration.

TABLE III.³ FINDINGS IN 100 AUTOPSIED CASES OF MITRAL STENOSIS

Age of death for men	42.7 years
Age of death for women	38.6 years
Duration of illness from onset of congestive failure	3.5 years
Number of patients fibrillating	50 years
Number with systemic emboli	46 years

hood of 69/34 millimeters of mercury, five died within eleven months of the physiologic studies. The pressures in the five individuals who died averaged 93/45 millimeters of mercury, suggesting that the person with the higher pulmonary pressure is in more immediate danger from his mitral stenosis.²

In Table III are given data in 100 autopsied cases of mitral stenosis reported before the antibiotic era and, of course, long before the advent of mitral valvotomy. This was a highly selected group in that all came to autopsy. It is apparent that the mean age at death was relatively young, being forty-three years for men and thirty-nine years for women. The data indicate that the duration of illness after the onset of congestive heart failure was only three and one-half years, and that of the entire group fifty had atrial fibrillation. It is also of interest that forty-six of the group had systemic emboli which constitute a special problem. It was also pointed out in this study that

TABLE IV.⁴ OPERATIVE MORTALITY IN MITRAL STENOSIS

of the disease without pulmonary hypertension can be compatible with a long and active life if systemic embolization does not supervene, whereas the most severe form of the disease may prove fatal. It would seem reasonable to consider what has been accomplished by valvotomy, particularly in those people who were more severely ill and could be classified as functional Class III to IV.

Of importance to any such discussion is the problem of operative mortality and the figures from one surgical group are shown in Table IV.⁴ The mitral valvotomies are listed in groups of 100 consecutively and are further divided into functional Class II and III as opposed to Class IV patients. It is seen that since the early days of this operation the operative mortality in the less severely ill patients has progressively dropped from

14 per cent to approximately 3 per cent, whereas the operative mortality in Class IV patients has remained more constant and in the neighborhood of 30 per cent. Mitral valvotomy does hold a considerable risk for the functional Class IV patient. Such a patient, however, is also subject to considerable risk by the disease itself and, in any given instance, it becomes a matter of individual evaluation.

It is generally agreed that approximately 70 to 80 per cent of the operated cases will show considerable functional improvement. The remaining patients will be unimproved for various reasons, including the presence of undetected disease of other valves, reactivation of acute rheumatic fever, the occurrence of systemic emboli at the time of surgery or soon thereafter, and also by the production of excessive mitral regurgitation at the time of operation. It would seem useful to attempt to quantitate the degree of improvement in such people by studying the same factors that were studied prior to operation, such as the pulmonary artery pressure, pulmonary flow, and pulmonary vascular resistance. In Table V¹ are given the data concerning six patients mentioned previously in whom preoperative and postoperative pulmonary pressures and preoperative and postoperative pulmonary resistance values are given and compared to normal values. It is important to remember that these patients were classified as functional Class III to IV prior to operation, and at the time of their postoperative studies were felt to be functional Class I and II. Both the pulmonary artery pressure and the pulmonary vascular resistance fell, but in this group there remained an elevation of pulmonary pressure post-operatively that was at least twice that of normal, whereas the pulmonary vascular resistance post-operatively was approximately one-half of the

preoperative value and roughly three times that of normal. The functional results as expressed by the patient's ability to do things did not correlate well with the physiologic findings.

In Table VI are summarized the data from a series of forty-five patients studied for a minimum period of three years following surgery.⁵ The evaluations are given at one year and at three years. There was a significant decline in good and excellent results, a significant increase in the fair and poor results, and a distinct increase in mortality. The question that remains to be answered concerns the future course of those patients still remaining in the good and excellent groups.

In December, 1952, the first fifteen patients operated on at the University of Minnesota for mitral stenosis were reported and their functional status was indicated at that time.⁶ These patients were operated on in 1950 or 1951 so that the minimum follow-up period is five years. In Tables VII and VIII are given the preoperative evaluations, the evaluation in 1952, and the evaluation in 1956. Only one patient has been lost to follow-up. It is quite evident that the functional improvement observed in 1952 has not been maintained in

1956, and that these people have now returned to their preoperative condition. One might argue that even though this is the case, these people might all be dead now if surgery had not been performed. In Table VIII are shown the data on four patients from this group who were explored and found to have too much mitral regurgitation to allow valvotomy. Of this group one has died, but he survived approximately three years. Patient DA stated that she felt considerably better following her operation although she is able to do no more than previously. She was especially gratified by the relative absence of edema which she attributed to the fact that she was never on a low sodium diet prior to surgery but followed it carefully subsequent to operation.

Patient BA is extremely difficult to evaluate. At the time of his original surgery there was too much mitral regurgitation to allow a valvotomy. He did make a striking recovery and returned from a preoperative bed-confined state to almost normal activity. This persisted for approximately six months, at which time he learned that nothing had been done at the time of operation. Following this, he once again regressed and within a few weeks was incapacitated.

Approximately two years later, he was re-examined and it was found that the cardiac murmurs had changed and suggested that he had primarily mitral stenosis. He was recatheterized and a further increase in pulmonary pressure was recorded. For that reason he was re-operated and relievable mitral stenosis was found. Subsequent to his second operation he once more returned to a functional Class I status, is now working every day, and in general is feeling well. This man represents the best clinical result from mitral valvotomy of the fifteen original cases, but in view of the improvement following his first operation, it is extremely difficult to evaluate him now.

From the information presented concerning operative follow-up, it would appear that, although in functional Class III to IV patients there may well be a prompt and gratifying remission of symptoms and improvement in the functional status, the permanence of this improvement is not known, and patients studied five years following surgery were found to be about in their preoperative condition.

It is not entirely fair to compare patients op-

erated in 1950 and 1951 with those operated on at the present time, because the performance of mitral valvotomy depends a great deal on individual surgical experience, and it would seem likely that valvotomies done today by an experienced surgeon are technically better than those early in the experience with valvotomy. Although the operation basically has not changed, much more now is known about the possibility of a recurrence of acute rheumatic fever following surgery, and, since it is now standard practice to place postoperative patients on prophylactic penicillin indefinitely, one may expect a decreased incidence of recurrent mitral stenosis. It is also possible that there has been an improvement in the selection of patients for surgery and that only those with relatively pure mitral stenosis are being operated on now, which should tend to give better surgical results. Obviously a further and detailed follow-up of the patients operated on early in the experience with mitral valvotomy is needed.

One particular group of cases deserves special attention. Embolization into systemic arteries in mitral stenosis is well known and may be catastrophic. Almost every group concerned with this particular problem has found that the incidence of systemic embolization in individuals operated on because of previous systemic embolization has been extremely low and in fact almost nonexistent. There would appear to be an added hazard of emboli occurring at the time of operation in this particular group, although such an impression might not withstand careful study of the data available. It is felt by some individuals, and probably correctly so, that the best indication for mitral valvotomy at the present time is the prior occurrence of a systemic embolus, with the idea in mind of not improving cardiac function particularly, but of preventing further emboli.

In summary, it can be stated that the functional Class I and II patients with mitral stenosis are not in need of surgical help ordinarily and that the operative mortality in functional Class IV patients is in the neighborhood of 30 per cent. Certainly, improvement does occur postoperatively in the great majority of patients subjected to mitral valvotomy, but this improvement appears to be of temporary nature in many cases so that one must consider the operation to be strictly palliative. The best indication for operation would appear to

(Continued on Page 788)

Cholesterol

A Clinical Appraisal in Relation to Coronary Artery Disease

L. RAYMOND SCHERER, M.D.

Minneapolis, Minnesota

THE PAST decade has shown an increasing interest on the part of the physiologist, physiologic chemist, pathologist, and clinician in the relationship of atherosclerosis to lipid substances in the blood. Aschoff¹ in 1924 discovered that the fatty portions of diseased arteries contained mainly cholesterol esters. Experimental studies by Anitschkow and Chalutow² demonstrated that atheromatous changes in the arteries of rabbits could be regularly induced by feeding cholesterol. Further experimental studies in rabbits, combining hypertension with feeding of cholesterol, revealed both an increased rate and degree of atherosclerosis. (Bronte-Stewart and Heptinstall³) No other animal responds in quite this manner. Ulrich⁴ in 1926 noted elevation of cholesterol in hypertensive patients as compared to normal controls. A tremendous amount of experimental study has been carried out by investigators. Gofman and his co-workers⁵ working on the lipoprotein molecule in serum with the ultracentrifuge did much to increase the general interest. Anfinsen,⁶ Gould⁷ and Page⁸ have made significant contributions. Katz and his co-workers are carrying on both clinical and physiochemical studies on a large group of patients with coronary artery disease.

We might briefly review some of the known or proven things about lipoproteins which have been established by various workers using Gofman's technique, in which the large lipoprotein molecule with the least density floats to the top. Three main classes of macromolecular lipoprotein substances are recognized. The first includes very large particles known as chylomicrons. These are found in normal lymph of the intestinal wall and are largely triglyceride substances. Their exact composition is not known. The second class is composed of beta lipoproteins of which about

25 per cent is protein and the balance cholesterol, phospholipid and triglycerides. Third, the alpha lipoproteins contain relatively more protein and less fat, and are of higher density. The last two are considered to have both structural and functional differences. It is the beta lipoprotein which probably is the most important substance in the atherosclerotic pattern. Experimental work points to the probable enzymatic control of the synthesis, transport and degradation of these substances as the basis for the understanding of their abnormal metabolism. The mechanism is as yet unknown. Anfinsen⁶ and his workers have shown that an enzyme, which they have referred to as "lipoprotein lipase," is concerned with the metabolism of these molecules and that it is activated by heparin. This enzyme is thought to exist in the tissues and plasma. The activating process of heparin is inhibited by protamine. The exact mechanism of these processes is not known, and much work must be done before it is understood.

Epidemiologic studies carried out by Keys⁹ have thrown important light on another phase. He has studied different populations with relation to the fat content of their diet, the incidence of coronary disease, and the cholesterol and beta lipoprotein content of their blood. He concluded that there were significantly lower concentrations of both cholesterol and beta lipoprotein and a lower incidence of coronary artery disease in populations with a low fat intake.

Storm and Jensen¹⁰ noted a decline in the mortality rate in diseases of the circulatory system in both males and females among Norwegians from 1941 to 1945, which coincided with severe dietary restrictions, principally foods containing fat. Following the war, the mortality rate returned to its previous level, this associated with return to a normal diet.

Not all workers interested in this subject are impressed with the lipid factor. McMillan¹¹ re-

Dr. Scherer is Associate Clinical Professor, University of Minnesota.

viewed many of the lesions and was impressed with what he calls the pleomorphic character of the lesions of arteriosclerosis. Many different things enter into it, such as necrosis, hyaline, fibrinoid and mucoid degeneration and pathologic calcification. He also admitted the high frequency or incidence of lipid deposits in these lesions. Warmann¹² reviewed other factors that may be involved in the atherosclerotic process. He emphasized that any ischemic injury to the arterial wall may be followed by an atherosclerotic plaque and that, secondly, there is evidence that the artery itself carries on metabolic processes and that this process may undergo a marked derangement in the diseased artery, resulting in abnormal deposits of phospholipid substances in the intima.¹³ Third, there is evidence that a primary thrombus in the arterial wall may result in atheromatous deposits. Lastly, vascularization and hemorrhage in the intima may be the primary factor, and atheromatous changes result from this injury. However, all of these pathologic processes seem to be associated with some disturbance in lipid metabolism.

Recent studies by Grieg¹⁴ suggest another theory of how the body deals with intravascular thrombi by fibrinolysis rather than by organization and incorporation of the thrombus into the vessel wall. Fibrinolysis was measured *in vitro* (estimated as tyrosine) in twenty-five healthy people, twelve men and thirteen women, ages nineteen to fifty-

six. Determinations were made after a fat-poor meal and a fat-containing meal. This revealed a conspicuous inhibition of fibrinolysis after the fat-containing meal, the degree of inhibition varied in proportion to the degree of lipemia, measured grossly by plasma turbidity. Exercise reversed to some extent the inhibitory process. The inhibition also was removed by giving the individual 10,000 I. U. of heparin twenty minutes before the specimen was taken. Finally, he determined that lipemia resulting from maze oil, unsaturated fats, did not inhibit fibrinolysis *in vitro*.

Ahrens et al¹⁵ noted a significant decrease in serum concentrations of free and esterified cholesterol and of phospholipids in six subjects when plant fats were substituted isocalorically for animal fats. This was carried out over a period of four months on a metabolic ward study.

The incidence of coronary artery disease in the American population seems to be definitely on the increase. Statistical studies of mortality rates among insured persons in the United States made by the Metropolitan Life Insurance Company¹⁶ revealed an incidence of 17 per cent mortality due to coronary artery disease in 1927, as compared to 42 percent in 1952. Coronary artery disease and cancer were the only two diseases that showed an increase in incidence. All others showed a decrease.

obtaining from co-operating physicians, revealed that the incidence of coronary artery disease increased from 20 per cent in 1925 to 44 per cent in 1950. All other types of heart disease decreased, save congenital heart disease and cor pulmonale.

Investigations into the alteration of the American diet have given some interesting results. Table I gives the index per capita of consumption of the major food groups. This indicates a marked increase in the consumption of fats and oils, excluding butter. There has been only a moderate increase of meat, fish and poultry. However, this does not take into consideration the change in fat content in certain meats, particularly beef, due to the intensive feeding and inactivity through which these animals are subjected today compared with several decades ago. Potatoes, flour, and cereals have shown a rather sharp decrease in consumption.

Table II, showing trends in consumption of dairy products, reveals a rather marked decrease in butter from 1935 to 1955, but at the same time a marked increase in margarine, which is derived largely from soy beans. The consumption of ice cream has increased over 100 per cent during the same period. There has been a moderate increase in cheese. During this same period, hydrogenation of fats has taken place, and this

has provided the housewife with a stable product, which needs no refrigeration, and is convenient to use.

The clinician is confronted with this apparent increase of coronary artery disease and the accumulating evidence tending to incriminate abnormal fat metabolism. What counsel should we give our patients? Most of us are aware of the fact that cholesterol levels may be reduced by markedly restricting fat in the diet, by the use of thyroid in the hypometabolic or myxedema patient, or by the use of estrogen in the hypercholesterolemia patient unresponsive to diet or not in the hypometabolic group. What is the desirable cholesterol level in man? It has been shown that cholesterol levels tend to increase from youth to middle age, and it would seem that cholesterol levels tend to be lower in the aged. Is it conceivable that the prolonged use of a high fat diet, such as we Americans utilize, could disturb homeostasis to any marked degree? Is the evidence sufficiently strong to disturb the dietary habits of individuals whose cholesterol levels are elevated? It is with this in mind, and probably to crystallize my own thinking, that a review of our clinical experience was undertaken.

This study was made upon a group of consecutive private patients, who were adequately studied either in our office or in St. Barnabas Hospital,

Minneapolis. There has been some attempt to classify blood cholesterol levels in relation to populations by their state of wealth or poverty. The group under study probably falls in the so-called

internal medicine. The fact that we live in a cold climate and in the middle of a dairy land may possibly influence the group under investigation.

(B.C.L.) (under 250 mgs. per cent, 250 to 300 mgs. per cent, and over 300 mgs. per cent). It was noted (Table IV) that approximately 80 per cent of the negative clinical examinations and 75 per cent of the nonvascular control group under age fifty had BCL's under 250 mgs. per cent, and 4 per cent and 6 per cent of these same groups had readings over 300 mgs. per cent. After age fifty, approximately 50 per cent of the women were shifted into a higher cholesterol classification, while the male shift was approximately 10 per cent. In a statistical study by Dr. Bearman (chi-square criterion), the two control groups were found to be essentially alike. However, in all statistical studies the negative clinical examination group was used as the standard for comparison.

Chi-square studies on the negative clinical examination group comparing men over and under fifty years of age revealed minimal difference in BCL concentrations, the over fifty-year age group showing only slight increase (Fig. 1). In comparing women to men under fifty years of age, there is a moderate increase in BCL in men (Fig. 2). There was, however, a striking increase in the BCL concentration in women over age fifty with negative examinations, as compared to men over fifty (Fig. 3) and to women under fifty (Fig. 4).

Table VII presents 220 patients with hypertension without known coronary disease. There

TABLE VIII. DIABETES MELLITUS WITHOUT HYPERTENSION OR VASCULAR DISEASE

was only a moderate shift of both male and female into higher cholesterol classification, the women again showing a substantial increase in BCLs after fifty years of age. Men over fifty with hypertension show only a moderate upward shift in BCLs, as compared to men with negative examinations (Fig. 5). There is even less shift in women in the same category (Fig. 6).

A small group of patients with diabetes mellitus without hypertension or known vascular disease was analyzed in the same manner. This group surprisingly compared very favorably with the control group, particularly in the over-fifty-year age category.

There were forty-one patients with a diagnosis of myxedema or hypometabolic state analyzed in the same manner. In the under-fifty-year age group, 73 per cent had cholesterols over 250 mgs. per cent; 100 per cent of the over-fifty-year age group had BCL's over 250 mgs. per cent and 69 per cent of the women and 50 per cent of the men had BCL's over 300 mgs. per cent (Table IX).

A group of thirty-nine individuals with a diagnosis of cerebral vascular accident and peripheral vascular disease were studied (Table X); five under fifty years of age had cholesterols not significantly elevated. Approximately 50 per cent had hypertension. In the over-fifty-year age group, approximately 70 per cent had BCL's over 250 mgs. per cent and more than one-third had hypertension. Eight per cent of this group had diabetes mellitus. There were seven additional cases not listed in this category that were listed under the coronary artery disease group.

A diagnosis of coronary sclerosis and insufficiency (not thromboses) was made in 124 patients, thirteen of whom were under fifty years of age and three of these were women (Table XI). Two of the women had BCLs under 250 mgs. per cent, one over 300 mgs. per cent, and hypertension was

present in two. Seventy per cent of the males had BCLs over 250 mgs. per cent. In the over-fifty-age group, there were 111 cases, fifty women and

36 per cent of the men had hypertension; diabetes mellitus was present in approximately 10 per cent.

In a group of eighty-seven patients, a diagnosis

sixty-one men. In 75 per cent of the women and 53 per cent of the men, BCLs were over 250 mgs. per cent; 54 per cent of the women and

of coronary thrombosis was made, sixteen were under fifty years of age, one of which was a woman with hypertension and a BCL under 250

mgs. per cent. Of the under-fifty-age group, 56 per cent had BCLs over 250 mgs. per cent, 31 per cent had BCLs over 300 mgs. per cent. There were seventy-one patients over fifty years of age in which 75 per cent had BCLs over 250 mgs. per cent, and 35 per cent had hypertension. Frequency polygons constructed by Dr. Bearman from his statistical analysis shows a fairly marked increase in BCLs in men over age fifty with coronary sclerosis as compared to men of the same age with negative clinical examinations (Fig. 7). Women over age fifty with coronary sclerosis have a moderate increase in BCL's as compared to men of the same age group with like diagnosis (Fig. 8). Men over fifty years of age with coronary thrombosis show a fairly marked increase in BCLs as compared to fifty-year-old men with negative examinations (Fig. 9). A marked increase in BCL in women over age fifty with coronary thrombosis as compared to women over fifty with negative examinations is shown in Figure 10. Further statistical analysis by Dr. Bearman,

comparing BCL's in men and women over fifty with coronary thrombosis, revealed a probability greater than .05 which would indicate a small difference and suggests that men and women in this category have approximately the same average BCL.

Methods of Reducing Blood Cholesterol Levels

Blood cholesterol levels dropped 50 to 100 mgs. per cent in sixty-four cases and over 100 mgs. in forty cases on dietary restriction only. This group, I believe, could be larger and the percentage drop in BCL's greater, if the patients were more meticulous with their diet. This was repeatedly demonstrated in patients who gradually became more interested or concerned with the importance of fat restriction. I learned early that substituting margarine for butter had no influence on BCL.

Cytellin was used in seven patients. This was effective to some degree, but there were a number that seemed to escape after it was used for a period. It is possible that the patients using this

gradually increased their fat intake, tending to diminish its effect.

Administration of thyroid extract was found to

usual care in detection, as they may possess none of the usual clinical characteristics of myxedema. A diagnosis of hypometabolism should be con-

Fig. 7.

*Coronary sclerosis

Fig. 8.

have a marked influence on BCL's in the myxedema and hypometabolic patient. The hypometabolic group, without myxedema, requires un-

sidered in any patient with an elevated cholesterol and even a low normal basal metabolic rate, who is unresponsive to a low fat diet. They may

respond rapidly to small amounts of dessicated thyroid. As an example, a woman, aged sixty, with a history of previous coronary thrombosis and a BCL of 600 mgs. per cent, was totally un-

and they tend to discontinue the medication when it occurs. So far, no males have been willing to accept this medication when the side effects were explained to them.

Fig. 9.

responsive to a very restricted fat intake over a period of several years. Her basal rate was minus 17 and 18 per cent. Peripheral vascular disease with claudication developed subsequently. The patient was given $\frac{1}{4}$ and $\frac{1}{2}$ grain of dessicated thyroid daily, with a resultant drop in BCL to 242 mgs. per cent in a few months. This was associated with a marked general improvement in her vascular picture.

Estrogen was used in a small group of women, who were unresponsive to dietary restriction, and, as has been reported by Barr,¹⁸ resulted in a marked drop in BCL. One patient, age fifty-two, with a BCL of 462 mgs. per cent and unresponsive to prolonged and rigid fat restriction, was given Estinyl, mg. 0.02 daily, with the BCL decreasing to 300 mgs. per cent. Estinyl was then increased to .02 and .04 on alternate days with a further reduction in BCL to 260 mgs. per cent. Uterine bleeding started, and the patient discontinued the medication. The BCL increased to the previous level within thirty days. I have found uterine bleeding generally disturbing to patients,

Summary

A group of 1,515 consecutive records of patients were analyzed in relation to blood cholesterol levels. The control group was composed of 974 patients, 402 of whom had negative examinations, 572 having nonvascular disorders. Chi-square analysis of the BCL of these groups proved them to be almost identical in behavior. Sixty-eight per cent of the combined control group had BCL's under 250 mgs. per cent. There was a striking upward shift of BCL in women more than fifty years of age.

BCL's of the control group were then compared to hypertensive patients without coronary disease, to diabetes mellitus, to hypometabolic patients, to individuals with cerebrovascular or peripheral vascular disease, and finally to a group of patients with coronary sclerosis and coronary thrombosis.

Patients having hypertension without known coronary disease had slightly higher cholesterol levels than the control group.

Diabetes mellitus did not seem to influence the BCL's as much as one would anticipate, 60 per

TABLE XIII. SUMMARY

	Cases Male and Female	Chol. under 250	Chol. 250-300	Chol. over 300	Hypertension
Control groups	974	68%	23%	9%	
Hypertension without coronary	220	52%	30%	18%	100%
Diabetes mellitus	30	60%	30%	10%

Coronary thrombosis	87	28%	37%	36%	32%
Total cases	1515				

Fig. 10.

cent of the diabetic patients having BCL's under 250 mgs. per cent.

Patients with peripheral vascular disease and cerebrovascular disease showed moderate deviation from the controls, 69 per cent having levels over 250 mgs. per cent.

The hypometabolic group was markedly different from the control, 86 per cent having BCL's over 250 mgs. per cent.

The coronary sclerosis group was quite divergent from the controls, showing 62 per cent with cholesterols over 250 mgs. per cent.

A marked rise in BCL was noted in the coronary thrombosis group.

Cholesterol levels were influenced by diet, Cytellin, thyroid, and estrogen.

No definite normal level for BCL's has been stated. It is apparent that these levels are altered

upward from youth into the fifth and sixth decades and tend to drop with advancing years.

Evidence indicating an increase of coronary artery disease has been pointed out. Data showing an increase in the content of fat in the American diet were also presented.

Recognizing that much of this evidence is indirect and so far no scientific data have demonstrated a direct causal effect, it would seem that indirect evidence should warrant careful study of patients in regard to cholesterol metabolism. Probably we should question composition of our present diet in regard to its high fat content, possibly looking with suspicion upon some of the newer compositions that have been added. Investigations being carried out in numerous laboratories on the effect of unsaturated fats in atherosclerosis hold real promise and may answer some disturb-

ing questions, such as the lack of atherosclerosis in the Eskimo. Much more study is indicated, and the final answer must wait upon scientific advancement.

Addendum

Subsequent to the completion of this paper, a group of patients were placed on corn oil, the amount varying from 1 dram to ½ ounce three times a day, and cholesterol determinations were made at an interval of two to four weeks. Most of these patients had been on restricted fat diets prior to this. The cholesterol level dropped between 25 and 50 mgs. in twelve patients, 50 to 75 mgs. in ten patients, and 75 to 100 mgs. in five patients. The cholesterol level became moderately elevated in four patients. It would seem that a relatively small amount of this unsaturated oil had about the same influence as a larger amount. These patients have all been on corn oil for a short period of time, and one should not predict what influence it might have over a long period of time, nor should one attempt to draw any conclusions at this time upon its influence on atherosclerosis. Only a prolonged period of subsequent observation will determine this.

DIODOQUIN IN THE TREATMENT OF CHRONIC DIARRHEA

Attention is drawn to the beneficial effects which may follow therapeutic trial of Diodoquin in chronic diarrhea. Nine cases of chronic diarrhea are reported. Seven had been studied carefully elsewhere. All had been diagnosed and treated as functional diarrhea. All patients complained of persistent diarrhea in spite of treatment. Several had developed very serious complications. All patients made a satisfactory response to this drug. The therapeutic trial can be accomplished as follows:

The patient is instructed not to change his medication or diet. Thirty 10-grain tablets are ordered. The patient is instructed to take one tablet at 9:00 a.m., one at 3:00 p.m. and one at 9:00 p.m. The doctor must avoid entering into a detailed discussion with the patient. If some explanation is unavoidable, the patient can be told that his diagnostic examination is continuing. He is asked to return in ten days.

If the disease is functional, the patient is likely to report no marked change. If the patient reports that he feels considerably stronger, that intestinal cramps and aching have decreased, that the stools are fewer and definitely better formed, and that gas, bloating and urgency have decreased—then real progress has been made.

Physical examination usually reveals less tenderness over the cecum and in the descending and pelvic colon. If this prevails, a second course is started, to last ten more days.

The physician must remember to explain that continued improvement may be interrupted by mild flare-ups. The usual course lasts thirty days. It is believed that no patient with recurrent diarrhea should be denied a therapeutic trial because all laboratory examinations have been reported negative.—A. L. JENKS, JR., *J. Iowa M. Soc.*, 47:529 (Aug.) 1957.

Evaluation and Management of Minor Contusions of the Eye

KENNETH L. ROPER, M.D., F.A.C.S.
Chicago, Illinois

OCULAR trauma is a large subject; therefore this discussion will be limited to minor contusions of the eye.

The "old-fashioned black eye" must not be belittled—at least by the eye physician consulted. A "black eye" is often the object of derision, the source of much humor and kidding; but it may be mute evidence behind which serious injury to the eye is hidden and which, if neglected, may turn comedy into tragedy.

All phases of human activity give rise to minor and major injuries. It behooves us to give thought to what to expect in the event of a national emergency when injuries will far outnumber our refractions and cataracts; then, certainly, contusions will be one of the major causes of ocular disability. Such injuries may appear insignificant on first inspection, but major complications may develop within a few days or a few weeks.

Concussions and contusions of the eye are caused by blunt objects, jarring or blasts; they are nonpenetrating.

The term "concussion" is best applied to changes which are in a large part reversible; but when the force of the impact has been sufficient to disrupt the walls of small vessels, the term "contusion" is more appropriately employed. It must be remembered that an external impact of sufficient force will cause internal lacerations, at the same time leaving the surface layers intact.

Since minor eye accidents occur very frequently, it is important to consider the normal anatomic and physiologic factors which protect the eye. The bony orbital margins are an important line of defense. The eye is well protected by the forehead, bridge of the nose, and the malar and zygomatic prominences. The globe is suspended within the socket and is cushioned by fat. The eye is movable

and gives way when pushed. The winking reflex, and the ability of the head to move rapidly and reflexly if an object is seen coming toward it are important safety mechanisms. All of these are factors in the protection of the eye, which otherwise would be injured to a much greater extent.

Because of the modern tendency of the injured to invoke legal procedure or at least to submit a batch of insurance papers to be filled out, it is extremely important that every traumatic case the physician sees be considered from a medicolegal point of view. This not only offers protection to the patient primarily, but also to the doctor who handles the case and to any third party, such as an employer or an outright attacker. Much of the viciousness of the present malpractice situation may be ascribed to carelessness in recording the facts, findings and observations in patients' records. It is easy to say "Oh, he just has a good old-fashioned black eye" and to be careless in the examination. A jury in court for malpractice may feel differently. Examination and history should be as thorough as time and opportunity permit.

History

First, and most important of all, is a short, concise but detailed, history. This must include the patient's full name, age, address and phone number; if injured at work, the name, address and phone number of the employer; and the name or names of persons who might have been attackers or in some way responsible for the injury.

One must know as much as possible about the cause of the injury—the kind, size and shape of the object that produced it. Such information often suggests the type of damage to look for and often makes a great difference in the treatment and prognosis. A blow on the eye with a fist and a blow from an explosion may look the same so far as the eye is concerned, but in one we will look for a retained foreign body and in the other we will not.

From the Department of Ophthalmology, Northwestern University School of Medicine, Chicago.

Read before the Sectional Meeting of the American College of Surgeons, Saint Paul, Minnesota, April 8-10, 1957.

The status of the patient's eye prior to the accident should be included in the history. This is a point of prime importance from the medicolegal angle. We are prone to assume that the patient's eyes were normal before injury; whereas we may be dealing with an amblyopic, previously injured, pathologic or actively diseased eye.

It is important to find out if the patient was wearing glasses or goggles at the time of injury and if possible to examine them for breakage or a bent frame. If the patient has glasses, it is of value to have in your record the lensometer readings of his correction. Myopic persons, for example, can be expected to suffer more often from retinal detachment than a hyperope. The same, perhaps, is true of the patient with an old healed chorioretinitis. These individuals should be examined more carefully and should be followed up with these factors in mind.

Examination

The most important aid in the examination of an injured eye is not a flashlight, not an ophthalmoscope, not a slit-lamp and corneal microscope, but a visual acuity chart. A visual acuity determination of some sort must be made—not of just the injured eye, but of both eyes—and if glasses are worn, the vision both with and without glasses. True, it may be inconvenient and time-consuming, but it is important. If the patient can only count fingers or see hand movements, we have reason to be concerned about the extent of his injury. On the other hand, if he can read 20/20, despite a tremendous ecchymosis, we are quite relieved.

Gross inspection is next. Most cases of ocular trauma affect one eye only and naturally, we examine this eye carefully. It is of valued importance to examine the uninjured eye and to use it as the "control eye" for comparison purposes as one's systematic inspection is carried out. Further inspection is then made with a loupe, oblique, retro- and slit-lamp illumination, as indicated in each case. Transillumination over wide areas of the sclera often reveal injury not disclosed by other methods of examination. Ophthalmoscopic examination is necessary for inspection of the posterior segment of the eye.

With minor contusions of the eye a variety of effects can occur making themselves evident in characteristic fashion in the various ocular structures. I shall mention and discuss briefly some of the resulting lesions.

Lesions of the Lids

Edema and hemorrhage.—Here the treatment is expectant; the suffusion is self-limiting and is best left alone to absorb. In the beginning, cold compresses are usually recommended, to be followed in twenty-four hours by warm applications and massage.

Emphysema.—This complication will occur with fractures of the nasal and ethmoid bones of the medial side of the orbit. Injudicious blowing of the nose will not only make the condition worse, but there is the danger of spreading infection from the nose into the orbit and eyelids. A "black eye" associated with bleeding from the ear must be treated as potentially very serious because the patient may have a skull fracture.

Lesions of the Conjunctiva

Hemorrhages.—In the conjunctiva, minor contusions may produce hemorrhages which may vary from small petechiae to extravasations of considerable size. Of themselves, they are of little importance. When the most dense portion is quite forward toward the limbus, it is likely only local bleeding. If the denser and more extensive part of the hemorrhage lies posteriorly, where no edge is apparent, and anteriorly does not reach the limbus, one can suspect it is blood that has tracked forward from the orbit following a fracture of the orbital walls or the base of the skull. Blood from a remote point is purplish, not bright red; also subconjunctival in site (rather than intraconjunctival) over which the conjunctiva can be moved.

Edema and chemosis.—Conjunctival edema and chemosis may occur. In minor contusions, this is of no consequence, but one must inspect carefully in these instances for ruptures of the sclera, et cetera.

Lesions of the Cornea

Edematous changes.—Often after slight contusions, edematous changes may be evident in the corneal epithelium, endothelium or substantia propria. The superficial edematous opacity may actually become an abrasion—the treatment of which is simple. In interstitial edema the opacity is associated with some pericorneal injection and subjective irritation, but it clears without specific treatment, frequently in a few days, although its final disappearance may be delayed for some weeks.

Blood-staining of the cornea.—Fortunately, this is a somewhat uncommon result of a contusion. It occurs with a massive hyphema and raised intraocular pressure. Treatment is unavailing once the opacity has developed.

Folding of corneal tissues.—Folds of Bowman's, but more commonly of Descemet's, membrane are an occasional result of contusions, producing deep striate opacities. Treatment is expectant.

Lacerations of the cornea.—If the cornea has been indented quite forcibly, interstitial tears of its tissue will occur. Bowman's membrane and the epithelium survive better in these instances because of their elasticity, but Descemet's membrane with its slight elasticity will give way. These ruptures are usually obscured by coincident edema of the corneal tissues, but as the endothelium repairs the defect by laying down a new membrane, this generalized opacity tends to clear. At other times, the formation of fibrous tissue leaves a permanent interstitial opacity. Frequently a high degree of myopia or irregular astigmatism results.

Lesions of the Iris and Ciliary Body

Traumatic Miosis and Spasm of Accommodation.—This condition is usually transient, followed frequently by iridoplegia. Often it lasts for a considerable period. No treatment is necessary, but if inconvenience is caused, the instillation of atropine may give relief.

Traumatic Iridoplegia and Cycloplegia.—A dilatation of the pupil is a very common sequel of a contusion of the globe. The functions of the iris and ciliary muscle are usually affected simultaneously. The pupil is moderately dilated with very diminished reaction to light and accommodation, both direct and consensual. The condition may resolve in a few weeks, but as a rule the deformity is permanent.

The symptoms following a lesion of this type concern mainly the impairment of the function of the ciliary muscle. This requires the use of a cycloplegia correction, and later the constant wearing of the full refractive correction for both distant and near vision. Miotics can be used to constrict the pupil and diminish any discomfort due to dazzling.

Vascular Changes.—Contusions initially produce an ischemic spasm of the uveal vessels, followed by prolonged reactive hyperemia. Clinically, one sees

circumcorneal injection and an edematous appearance of the iris. Slit-lamp examination will reveal a flare due to the presence of increased protein in the anterior chamber. Such manifestations disappear very rapidly.

Small hemorrhages in the iris are merely a further extension of the hyperemia and exudative reaction just described. They are of no special importance and are absorbed in a few days.

Traumatic hyphema is an accumulation of free blood in the anterior chamber, is a logical sequence of the same process, and is a common observation in mild contusions of the eye. Such hemorrhages usually absorb rapidly, but the picture may be complicated by the occurrence of secondary hemorrhages.

Complications may arise with hyphema, particularly when it is massive and when secondary hemorrhages occur. The most important is the occurrence of secondary glaucoma, and associated with the rise in tension is the development of blood-staining of the cornea.

Traumatic hyphema, particularly the recurrent type, has been generally overlooked in ophthalmologic textbooks, and the literature concerning it is meager. In the presence of hyphema, expectant treatment without the instillation of atropine is probably the safest course, as long as the tension is normal or low. The use of any mydriatic seems unnecessary and may be dangerous. From the theoretical point of view, the greater the surface of the iris available, the more rapid will be the absorption of the hyphema. In those cases where treatment is indicated a miotic is suggested, since mydriasis may actually embarrass the drainage channels. If the entire chamber is filled with blood, and at the earliest moment if a raised tension appears, a paracentesis should be done.

Lacerations of the Iris and Ciliary Body.—Small tears and lacerations of the iris and ciliary body after comparatively slight injuries are more common than is realized. Tears of the sphincter muscle are often difficult to see clinically, and are made most obvious by transillumination, in which case the torn area appears as a reddish glow. Changes in the pupillary contour and local embarrassment of dilatation are findings associated with such tears.

Tears at the pupillary border are common and generally involve the whole depth of the tissue, anterior stroma, sphincter and pigment epithe-

lium. Only when the sphincter itself is torn is there a permanent functional disability. In these lesions no treatment is of value.

Iridodialysis.—When the trauma is of considerable severity, the iris may be to a greater or lesser extent torn away from its insertion into the ciliary body. In most instances the tear is small, and depending on the size of the tear, the pupillary margin is deformed, becoming flattened opposite the lesion. In most instances, after the usual period of rest and expectancy, no treatment is required.

Inflammatory Changes.—Vasodilatation and varying degrees of inflammatory reaction in the anterior uveal tract occur after contusions. The reaction may be transient and of little consequence, but one must bear in mind that even extensive changes (edema and inflammatory infiltration, subsequent development of fibrous tissue which replaces muscle fibers, and eventually atrophy) can occur after comparatively trivial contusions.

Pigmentary Changes.—Following minor ocular contusions one almost always sees a powdering of uveal pigment on the surface of the iris, back of the cornea, the anterior lens capsule and frequently in the vitreous. The corneal pigmentation is usually transient, but the deposits on the lens and in the vitreous tend to be permanent.

Direct blows on the eye may leave an imprint of the pigmented pupillary border on the anterior lens capsule. Vossius ring is interesting by itself, but is not dangerous and usually clears up within a few weeks.

Lesions of the Lens and Zonule

Lens Opacities.—Next to hemorrhage in the eye, the most noticeable result of contusion, although not always immediately visible, is lenticular involvement. Injury to the lens and its supporting mechanism occurs with unexpected frequency even after minor contusions of the globe—in 60 per cent of cases according to Davidson.*

Contusion cataracts may be associated with or without a capsular tear. The opacification in the

first type is due to the free entry of aqueous into the lens; in the second, to a derangement of the normal semipermeability of the capsule leading to a similar but less dramatic imbibition of fluid. Even in the observable presence of a tear in the anterior lens capsule, the opacification may remain localized or even disappear so that normal vision results.

A great variety of lenticular changes follow contusions. As a rule the opacity is localized and stationary, with quite characteristic morphologic appearances.

Apart from the rapid development of a diffuse cataract in the presence of a large capsular tear, the prognosis of contusion opacities in a lens under the age of thirty is good, while after this age it should be guarded.

Subluxation and Dislocation of the Lens.—Injury to the suspensory mechanism of the lens is a common sequel of contusion. It is quite understandable that if the zonule is already degenerate or atrophic, as occurs in the elderly, in high myopia or in old uveitis, an injury so slight as rubbing the eyes may cause dislocation of the lens.

Partial dislocation or subluxation is frequent. The clinical appearance, signs and symptoms of the dislocated or subluxated lens are well known. Occasionally, the eye remains quiet indefinitely. Usually less fortunate events ensue and traumatic opacities appear, but more frequently, perhaps, is the complication of a violent irritative iridocyclitis and a secondary glaucoma.

In complete traumatic luxation the lens will be found in the vitreous twice as often as in the anterior chamber. It is better tolerated in the vitreous. If it is dislocated into the anterior chamber, an intractable iridocyclitis and fulminating glaucoma supervenes.

The treatment of subluxation and dislocation of the lens presents problems of unusual difficulty in pre-operative judgment and operative technique. In recent years I have handled cases of subluxated lenses much more successfully than I did some years ago. Anesthesia is most important. Essential requisites are full akinesia of the facial nerve, a retrobulbar injection with Wydase®, a prepared conjunctival flap and three preplaced sutures. Capsule forceps are dangerous, whereas extraction of the lens without vitreous loss is often possible with the erisophake. A wide iridectomy and scoop extraction are often necessary.

*Davidson, M.: The minor sequelae of eye contusions, *Am. J. Ophth.*, 19:757-769 (Sept.) 1936. Lens lesions in contusions: A medico-legal study, *Am. J. Ophth.*, 23:252-271 (Mar.) 1940.

Lesions of the Choroid

The choroid suffers the same type of contusion effects as the iris. The wave of pressure causing the vitreous to force the choroid against the resistant sclera and the rebound gives rise to a traumatic ischemia, followed by a reactive hyperemia with edema and hemorrhage. To this must be added the possibility of lacerations involving tearing of the blood vessels and stroma.

The symptoms of a choroidal rupture vary with the site. The function of the overlying retina is always destroyed.

The treatment of choroidal rupture is rest and expectancy.

Traumatic choroiditis varying in size and distribution frequently follows the traumatic vascular reaction characteristic of contusions. The symptoms of traumatic choroiditis correspond with those of a mechanical rupture, and treatment again is expectant.

Lesions of the Retina

Damage to the retina after even minor contusions to the globe, affecting particularly the macula and periphery, is common. The contusion causes necrosis of nerve cells, edema and hemorrhage with minute lacerations of the tissues themselves. In the retina these changes are especially important. The ophthalmoscopic picture of abnormality may be transient, but the after effects can be permanent and disastrous. Slight pigmentary changes at the macula, often seen with difficulty and readily overlooked, may permanently impair central vision to a degree far greater than the clinical picture would suggest.

Again, degeneration in the periphery of the retina or a small tear in this region may lead to a retinal detachment a considerable time after the contusion.

Contusion injuries to the retina carry unusual medicolegal importance and careful and repeated examinations of the fundus should be made after any accident.

Lesions at the Optic Disk

Papillitis causing considerable swelling of the disk may be associated with ocular contusions of moderate severity, and, of course, optic atrophy may be a sequel of widespread retinal or choroidal damage.

Effects on the Vitreous

Even in minor contusions we can expect to find changes in the vitreous. As a result of the reactive vasodilatation, a plasmoid diffusion rich in protein appears in the aqueous, which penetrates the vitreous, disrupting its framework and leaving elements deposited on its fibril framework.

Vitreous hemorrhage is a common observation in minor contusions originating probably from the ciliary region. Absorption of these hemorrhages is usually slow, and little can be done therapeutically to hasten resolution.

Minor contusions rarely cause damage to the sclera. Ruptures of the sclera occur in instances of both direct and indirect contusion.

Changes in Refraction

Post-traumatic changes in refraction are well known, occasionally involving a hypermetropia, but more commonly myopia.

Traumatic hypermetropia is usually associated with paralysis of accommodation and may be either temporary or permanent. Bifocal glasses may have to be used in order to tide the patient over in his near work. Organized material beneath the retina after rupture of the choroid explains the phenomenon in some cases. Posterior dislocation of the lens with increased depth of the anterior chamber will, of course, change the refraction in the direction of hypermetropia.

Traumatic myopia is the more common refractive change following contusions of the globe. Ciliary spasm probably accounts for most of the cases and explains why they improve in a few days. If the refractive change persists, the plausible explanation is damage to the suspensory apparatus, permitting an increase of the lenticular curvature.

Changes in the Ocular Tension

Contusions often affect ocular tension and when this is so the tension tends to be unstable, sometimes being raised, sometimes lowered. This instability is often shared to some extent by the uninjured eye. Usually the instability passes without serious effects, but a severe and intractable glaucoma can be an end result as well as a persistent hypotony. The underlying cause in all such cases is probably vascular in origin.

Treatment of Tuberculosis in the Aged

THOMAS J. KINSELLA, M.D.
Minneapolis, Minnesota

THE PAST generation has witnessed many changes in the makeup of the population in this country. The more adequate food supplies and better facilities for their distribution have decreased deaths from famine. Better living conditions and improved health measures have reduced mortality rates and eliminated epidemics which formerly depleted populations. Medical science, antibiotics and chemotherapy have saved thousands of lives that otherwise would have been lost. These and many other factors have resulted not only in an increasing population, but also in a greater percentage of older individuals. These shifts have brought new responsibilities to the medical profession, and particularly to the sanatoria treating tuberculous patients.

About thirty years ago, the usual patient entering the sanatorium with active tuberculosis was a young girl between fifteen and twenty-five years of age. At this time the females outnumbered the males by a wide margin. Today the average patient entering the sanatorium is an elderly male, often discovered to have tuberculosis by a routine chest x-ray taken in the city jail where he was detained for drunkenness. The routine general hospital admission x-rays are responsible for the discovery of many cases and the x-ray screening of inmates in homes for the aged and rest homes account for others. Some are discovered as a result of studies of contacts of known tuberculous patients.

That the shift in the age distribution is not a local phenomenon is well demonstrated in the accompanying tables.

There was a time when tuberculosis in the older age groups was considered to be a slow chronic process which smoldered along without too much reaction on the part of the patient and without too much damage to those around him. Such individuals were thought to possess good resistance and to handle their disease quite well. When bed rest constituted our chief weapon against tuberculosis, the results from treating older persons were not particularly good, because it was found in-

advisable to keep these patients immobilized for long periods of time because of the intercurrent complications which developed. Nor were collapse therapy measures of great help.

Increasing experience and knowledge has shown that many of our previously-held ideas and notions concerning the age and development of tuberculosis in these people were not true. The previous concept that the tuberculosis in many of these persons had been present for years and merely smoldered along has frequently been disproven by the records of previous tuberculin tests or a review of previous x-ray films. This may have been true many years ago when most of our population received their contamination and infections early in life, but does not hold today when the vast majority reach adult life or even middle age without having acquired a tuberculous infection. It is not at all uncommon to have people of advanced years, even up into their eighties, present an apparently primary pleural effusion or a massive apparently primary parenchymal infiltrate similar to those we used to see in young people, and at the same time have medical records of previous tuberculin tests or chest x-ray films of fairly recent date to prove that these lesions did not exist a short time before. Likewise, the response of many such lesions to specific treatment has been too rapid for old chronic fibrotic disease.

The diagnosis of tuberculosis in the aged is frequently delayed or missed because of past disease or previous diagnosis of associated conditions which may simulate, mask or obscure the tuberculous process. Probably the most frequent mistake that is made lies in accepting a previously established diagnosis of bronchitis, bronchiectasis, asthma or emphysema without making adequate studies to be sure there is not also an associated condition. Unless the physician carries with him a high index of suspicion for tuberculosis and carcinoma when confronted with any pulmonary condition in an older patient, he will not infrequently fail to arrive at the correct diagnosis.

Tuberculosis is where we find it, in all ages, all

ances, and all circumstances of life. Especially confusing from the clinical standpoint are the patients who present, not one, but two or three different conditions at the same time, such as bronchogenic carcinoma and tuberculosis, bronchiectasis and tuberculosis, bronchial asthma, pulmonary emphysema and tuberculosis. The tubercle bacilli disseminated by such a patient are just as infectious as those of any other open active case of the disease and are more dangerous to the attending nurses and to the family or associates, because no precautionary measures are invoked.

There are certain groups who should always bear careful scrutiny because of the increased incidence of tuberculosis among them. These include patients with diabetes, alcoholism, silicosis, the mentally disturbed, those receiving cortisone, and some who have had an extensive gastric resection. In some of these, it is probably not the original condition *per se* which is responsible, but rather the semi-starvation or associated undernutrition. It has been estimated that approximately ten per cent of all diabetic patients develop tuberculosis. It is likely to develop insidiously and not infrequently in a rather bizarre and unusual manner, often with basal or midlung involvement rather than the more usual apical or posterior segmental distribution. Certainly all diabetic patients should be carefully watched, and particularly those presenting a positive Mantoux test. A chest x-ray study at least every six months would appear to be warranted.

Chronic alcoholic individuals are not too careful about their habits and associates, and over long periods of time allow their drinking to interfere with their nutrition and rest; hence they are more than usually susceptible to the development of tuberculous disease. Each year our sanatoria admit a number of persons whose tuberculosis was first discovered following routine x-ray studies of the chest of inmates of the jail or workhouse, detained there usually because of drunkenness. These same alcoholics subsequently become a serious disciplinary problem in the sanatorium because of their drinking propensities.

The high incidence of tuberculosis among patients suffering from silicosis has long been known to the medical profession. These people require repeated and careful screening to detect tuberculosis before it has progressed too far, especially among those who are tuberculin-positive. It is essential that these persons be discovered

TABLE I. AGE DISTRIBUTION IN TUBERCULOSIS

	1925		1955	
	Under 50	Over 50	Under 50	Over 50
Glen Lake Sanatorium 518 admissions	M 206 F 265	33 405 14	M 113 F 118	123 51
	471	47 9.05%	231	174 42.9%

	1955	41	21	38	271

promptly so that they may be removed from their usual work and contact with their fellow workers, many of whom may also have silicosis. From the standpoint of treatment, they must be treated early and intensively to avoid an unfavorable prognosis.

The insane and others who are mentally disturbed often have poor hygienic habits, have feeding problems which interfere with their nutrition, and are frequently in contact with others who are ill. These same factors apply to the senile as well as to the truly insane. Repeated and careful observation should be made of all such patients.

Many older persons suffer from arthritis and not a few from the rheumatoid type. The present tendency of physicians to use the steroids in the treatment of these and other conditions has brought to the sanatoria some patients who have developed tuberculosis or whose old tuberculosis has flared up following steroid therapy. A note of caution, then, should be sounded in using such therapy in any patient who has any evidence of previous tuberculosis, even if apparently obsolete and perhaps also in any patient presenting a positive Mantoux test. If the steroid therapy must be administered for the relief of symptoms which cannot be alleviated in any other way, then the advisability of giving concomitant anti-tuberculosis therapy should be given serious consideration.

Patients who have had an extensive gastric resection, either for ulcer or for malignant dis-

ease, may present serious nutritional problems because of anorexia or other reasons. When the general nutrition is impaired, these persons may become good candidates for acquiring or developing tuberculous disease. Most sanatoria have occasional patients in this category. Their successful treatment is not an easy problem.

Treatment

Adequate treatment of tuberculosis in the elderly individual is essentially the same as the treatment of tuberculosis in others, modified to meet the needs and limitations of the elderly patients. This consists essentially of isolation, a modified rest program, specific anti-tuberculosis therapy, complete general study of the individual, and later, perhaps, surgical therapy by collapse or resection of specific areas of the lung.

Isolation.—While it may seem cruel to uproot these elderly people from their homes and families and familiar surroundings, it must be remembered that we are dealing with an infectious and contagious disease in whose management maudlin sympathy should play no part. The tubercle bacilli from these patients are just as dangerous as those from any other case of active tuberculosis. The danger of their disseminating disease is considerably greater, because many of them are careless in their habits and will not co-operate or use the ordinary sanitary precautions which other patients rapidly learn. These patients should be admitted to the sanatorium where they may be isolated, thoroughly studied and adequately treated, for home treatment of tuberculosis is frequently nine parts home and one part treatment. It is almost impossible to keep children away from their favorite grandfather who will still slip them candy from his pocket and tubercle bacilli with it.

Modified bed rest.—Previous treatment programs which placed so much reliance on strict bed rest have never been particularly good for the elderly patient. Prolonged immobilization in bed, in spite of good nursing care, frequently results in decubitous ulcers, contractures, and fixation of joints already stiffened by arthritis, hypostasis and embolic phenomena, all detrimental to the aged patient.

Modern treatment with specific anti-tuberculosis medications no longer requires such strict bed rest, and while a modified restriction of activities is

probably advisable, these patients should be kept ambulatory at least to the extent of bathroom privileges if at all possible, perhaps even to a certain extent during the febrile period of their illness.

Specific anti-tuberculosis therapy.—Specific drug or antibiotic therapy in the chemotherapeutic era has added much to the therapy of tuberculosis, but probably more to this group than to any other. Drug therapy in the aged should be just as intensive and along the same lines as utilized in other patients with tuberculosis. Some concessions may have to be made, however, in some cases as in the younger group. The emaciated person with poor gluteal muscles may not tolerate repeated Streptomycin injections, whereas the patient with a poor appetite, digestive disturbance, or a previous gastric resection may be a poor candidate for large doses of PAS. Most remarkable changes may occur in the disease in some of these people, indicating that some of the lesions are of recent origin and are not the old chronic fibrotic lesions which we once thought existed in many of these patients. In no other group has extremely prolonged chemotherapy found a better place than in the treatment of the aged, for, if such a patient may be kept symptom-free and culture-negative, he may perhaps with safety be returned to his home, to the home for the aged or a rest home, even if he must be kept on chemotherapy for the remainder of his life. Not infrequently the problem of resistant organisms may be encountered in these patients as it will in others who have had previous or inadequate chemotherapy. This will have to be met by the substitution of other antibiotics to which the organisms are still sensitive.

Complete study of the individual.—A complete and careful study of the entire patient is especially important in this group, for elderly people are more likely to have other ailments in addition to the pulmonary tuberculosis. Unless all such factors are realized and evaluated, no true estimate of the patient's true condition or his ability to withstand any contemplated additional procedure can be ascertained. A complete history and physical examination are, of course, fundamental. Complete blood and urine studies are routine. A complete cardiovascular workup including blood pressure, electrocardiogram, and, perhaps, venous pressure and circulation time are essential if any

surgery is contemplated. Old age and pulmonary disease add to the burden the heart must carry and any additional thoracic surgery may add very materially to the load. Renal function studies and at times liver function studies may also be advisable. Pulmonary function studies are extremely important if the inroads of age and disease are to be ascertained, for any surgical intervention will inevitably interfere with this respiratory function. Bronchial spasm, asthma, emphysema, fixation of chest wall by arthritis or the diaphragm by age, adhesions or previous surgery may be important factors in the patient's ability to tolerate any contemplated surgery. The timed one-second and total vital capacity, maximum breathing capacity, exercise tolerance to walking or climbing and at times bronchspirometry may be necessary in order to get a complete evaluation of local conditions.

X-ray studies, both in the posterior-anterior and lateral projections, over-exposed films, planigrams and perhaps bronchograms may be essential to a proper evaluation of the pulmonary lesion. Bronchoscopy, local biopsy and collection of specimens by aspiration for careful microscopic study for malignant cells and culture of the material for secondary organisms, fungi, and tubercle bacilli, may be essential. It becomes the duty of the clinician in charge, with all of this information available, to evaluate it and to make the decision whether surgical intervention is advisable or necessary.

Surgery.—Many patients in the older age group present disease which does not clear completely under conservative measures plus chemotherapy. They may present conditions which in younger persons would immediately be accepted as suitable lesions for collapse or surgical excision. Before pneumothorax had fallen into disfavor, numbers of these people in the older age group were successfully treated by this means. Now with specific drugs available to control the tuberculous complications previously encountered, it may still be used to advantage in certain older persons not suitable for the more drastic types of therapy.

The idea of collapse therapy for our older patients is not new, nor is its application to this group a new departure. The first thoracoplasty carried out at Glen Lake Sanatorium in 1922 was on a sixty-four-year-old man, who not only survived the procedure but was rehabilitated to

TABLE III. AGE DISTRIBUTION OF RESECTIONAL SURGERY IN PATIENTS OVER AGE FIFTY

useful work and survived for eighteen years, eventually dying of arteriosclerotic gangrene of both feet. Many others have been carried out over the years, were fairly well tolerated and gave some very satisfactory results. They might still be performed to advantage today in certain individuals. Extra-pleural, or more preferably extra-periosteal plombage, might be used to advantage occasionally, as it possesses the advantage of maximum collapse for one procedure without the disadvantage of chest wall motion from thoracoplasty of comparable degree. Even when such procedures prove inadequate after they are carried out, they may still be of value in setting the field for subsequent resection if it becomes indicated. The possibilities of surgical resection of residual significant cavitary or symptom-producing disease has always been a tempting one to the surgeon, but it has been necessary to exercise caution and establish certain limits with this type of treatment in older people. The general surgeons have taught us that it is perfectly possible to repair hernias, plate or pin fractured hips, and perform abdominal surgery on patients of almost any age, even those one hundred or more years old. These procedures, of course, do not upset the cardiorespiratory physiology the way intrathoracic surgery does. The thoracic surgeon works much closer to "where people live" than the general surgeon, and his procedures are more hazardous to the older individual than the major surgery of the abdomen, pelvis, or skeletal structures.

Under certain circumstances the possibilities of using some of the older forms of collapse therapy

now out of style might be considered to control tuberculous disease. Pneumothorax, phrenic nerve operations, and some of the extrapleural or extrapariosteal procedures, usually well tolerated even by poor risk patients, might at times be used to advantage in this group. We do not consider them as reliable as the resectional procedures, but occasionally they may be of a distinct help. During the past decade we have performed resectional surgery on 124 patients beyond the age of fifty up to and including two who were seventy-five years of age, as shown on Table III.

The procedures carried out included thirteen pneumonectomies, thirty-three lobectomies, seventy-five partial lobectomies, with three bilateral resections as shown in Table IV.

This group has included eight diabetic patients (6.5 per cent) ranging in age from fifty-seven to sixty-nine. There were ten Indians (8 per cent) ranging in age from fifty to seventy-five. The operative mortality has been satisfactorily low (2.4 per cent); there were three deaths within the two-month period following surgery: one woman, aged sixty-one, two days after right middle and upper lobectomy under thoracoplasty, from coronary occlusion; one woman, aged sixty-three, on the day of pneumonectomy and six-rib thoracoplasty, from pulmonary edema; one man, aged fifty-four, sixteen days postoperatively, following a left partial upper and lower lobe lobectomy, from a pulmonary embolus. One additional patient, a man aged sixty-seven, who had had bilateral partial resections with partial thoracoplasties, died six months following his last surgery from gradual decline. His tubercle bacilli were resistant to many of the antibiotics. He had tolerated his operative procedures surprisingly well.

The complications encountered have been similar to, and no more frequent than in, the total resection series, and have been more closely related to bacterial resistance than to patient age or the disabilities of age.

It is often physically impossible and more frequently surgically inadvisable to attempt to re-

sect all tuberculous disease in these elderly patients. Our surgical attack should be directed at removal of significant residuals, caseous abscesses, open or inspissated cavities, symptom-producing bronchiectatic areas, leaving old scarred and fibrotic nodular disease areas of smaller size undisturbed. There is little virtue in excising so much pulmonary tissue that the patient is left a respiratory cripple without sufficient capacity to enjoy life. Our aim should be to remove symptom-producing and bacteria-dispersing lesions so that the patient no longer is infectious or dangerous to those around him and may safely be returned to ordinary living conditions.

Because of extensive emphysematous changes so frequently found in these people, special precautions must be taken in resecting these lesions to prevent serious air leakage and persistent pneumothorax postoperatively. When resecting localized lesions from such lungs, the clamp-and-suture method of excision more satisfactorily controls air leakage than the conventional segmental resection.

Care must be exercised in the handling of these elderly patients to avoid even short periods of cyanosis, if myocardial or cerebral damage is to be avoided. Oxygen must be used frequently. Fluctuations in blood pressure, either up or down, must be anticipated and prevented if complications are to be avoided. The legs must be wrapped and early and persistent active motion of the lower extremities insisted upon in an attempt to prevent venous stasis, thrombosis or embolic phenomena. Efficient nursing care with kindness, encouragement and assistance in their coughing and moving are especially important for this group of patients.

Much can be accomplished by intensive treatment, chemotherapy and the judicious use of surgical procedures in the management and rehabilitation of the elderly tuberculous individual. The extra care and attention required in the treatment of these patients will be more than amply repaid by the results which can be obtained in treating them.

TUBERCULOSIS CONTROL

Until recently the emphasis of tuberculosis control programs has been centered on mass surveys, mobile roentgenographic units, and hospital admissions, while a segment of the population with one of the highest rates of infection has been somewhat neglected. Continuous case-finding programs in prisons offer a fertile field for the control of tuberculosis for several reasons.

The increased prevalence rate of the disease in prisoners makes such programs much more rewarding than are those which are carried out in the general population.—HARVEY I. MEYERS, M.D., GEORGE JACOBSON, M.D., and FRANK W. OECHSLI, M.D., *Am. Rev. Tuberc.* (Oct.) 1956.

Cutaneous Manifestations of the "Carcinoid Syndrome"

ALVIN S. ZELICKSON, M.D.
Minneapolis, Minnesota

THE CARCINOID syndrome recently has become popularized by the work of Rosenbaum,¹ Isler,² Thorson³ and their co-workers. Its manifestations are protean but, since one of its earliest and chief symptoms may be dermatologic, a review of the cutaneous changes seems justified.

The syndrome, as described by Thorson et al,³ consists of the following five components:

1. A slowly growing, malignant carcinoid of the small intestine with metastases to the liver or other, especially intra-abdominal, organs. Dependent edema, change in bowel habits, occasional episodes of ileus and abdominal pain may occur secondarily. Ascites and pleural effusion occur less frequently.

2. General dilatation of the small vessels of the skin and, in some cases, telangiectasia are present.

3. Plethoric coloration and generalized or blotchy cyanosis in the absence of polycythemia have been observed, as has peculiar, patchy flushing of the skin.

4. Pulmonary stenosis of the valvular type and tricuspid regurgitation may be associated with the aforementioned findings.

5. Finally, the patient may complain of atypical attacks of bronchial asthma.

Lubarsch⁴ first described the carcinoid tumor and distinguished it from the more common adenocarcinoma of the small bowel. Bunting⁵ commented on the histologic resemblance of the tumor to a basal cell carcinoma, while Oberndorfer⁶ first used the term "carcinoid" to describe this new-growth.

Carcinoid tumors are most commonly found in the small intestine, although all parts of the gastrointestinal tract below the esophagus, including the gall bladder and appendix, may be involved. Reported extra-alimentary sites include the ovaries and lungs. The tumors are composed of argentaffine cells which are normally found in these various organs. Masson demonstrated the same silver staining characteristics of both the argentaffine cells of the gastrointestinal mucosa, and the cells of the carcinoid tumor, hence the

synonym argentaffinoma. It has also been shown that these cells have an affinity for chromium, and therefore are often referred to as chromaffin cells. Macroscopically, the tumor is firm, rubbery and of a pale yellow color. Microscopically, the growth is composed of small, irregular solid masses of cells supported by a scant connective tissue stroma. The cells have poorly defined cytoplasmic borders and dark basophilic nuclei, which are round and vesicular. Many cells show vacuoles in the cytoplasm, apparently containing a lipoid substance. The cytoplasm also contains specific granules which stain with silver or chromium salts, as well as with eosin.

The argentaffine cells secrete both serotonin (5-hydroxy-tryptamine) and glucagon. Serotonin appears to play a definite role in the development of this syndrome and may also be found outside the argentaffine cells, adsorbed to platelets, in the spleen, brain, glandular tissue, and in the tumor itself. It is normally excreted in small amounts in the urine of humans and dogs. Serotonin is broken down by mono-amine oxidase into a metabolite (5-hydroxy-indole-acetic acid) (5-HIAA) which is excreted in the urine in high amounts in cases of proved carcinoid tumors.

Several hypotheses have been advanced by McKusick⁷ concerning the physiologic actions of serotonin.

1. It is a factor in hemostasis by production of vasoconstriction.
2. It contributes to the control of vascular tone and therefore of arterial blood pressure.
3. It plays a role in the normal function of the central nervous system.
4. It participates in the regulation of renal function.
5. It helps to regulate normal intestinal tone.

The chief dermatologic manifestations of the syndrome are as follows:

1. Reddish-blue cyanosis of the face resulting from pulmonary stenosis.
2. Telangiectasia over the central portion of the face.
3. Thickening of the skin and urticaria of the face.
4. The most characteristic symptom is a bright to

From the Department of Dermatology, Minneapolis General Hospital, Carl W. Laymon, M.D., Director; and the Division of Dermatology, University of Minnesota, Francis W. Lynch, M.D., Director.

deep purple flush. The flush may be brought on by alcohol, emotion, food, spices, or have no apparent cause. It has an abrupt onset with rapid spread from the neck to the chest and face, including the conjunctivae, and then to the upper arms. There is increased warmth and a burning sensation in the parts affected, with simultaneous bitemporal headache. After one to fifteen minutes the symptoms subside spontaneously, leaving no residuals.

Thorson et al³ divided the flush into four different stages:

1. Diffuse reddening of the face and the neck.
2. Disappearance of the flush, or spread to the trunk and extremities.
3. The flush disappears in a blotchy manner, leaving sharply demarcated, irregular deep red plaques which stand out against the surrounding normal skin. These patches are often surrounded by broad, blanched margins. They may enlarge and coalesce.
4. The final stage is characterized, in addition to the aforementioned lesions, by cyanotic areas of varying intensity and location. The different stages vary in intensity and duration.

The clinical picture is usually diagnostic but laboratory studies may be of aid. The following are readily available:

1. A qualitative colorimetric screening test, described by Sjoerdsma and co-workers,⁸ for 5-hydroxy-indoleacetic acid, employing 1-nitroso-2-naphthol. The technique is as follows: Mix 0.2 ml. of urine, 0.8 ml. of water and 0.5 ml. of 1-nitroso-2-naphthol solution. Then add 0.5 ml. of nitrous acid and mix again. Let stand ten minutes, then add 5 ml. of ethylene dichloride and shake. A positive test is a purple color in the top layer.
2. Roentgenologic examination demonstrates tumors of the gastrointestinal tract.

It must be remembered that only 20 per cent of carcinoid tumors are malignant and this syndrome apparently occurs only in those cases with metastases, especially to the liver. The syndrome, therefore, has a serious prognosis.

Report of a Case

G. B., a white man, aged seventy-one years, was admitted to the Minneapolis General Hospital in January, 1957, complaining of sharp abdominal pain made worse by eating and relieved by belching or vomiting. He stated that the pain had been present intermittently for the past four years, occurring approximately once every two months and lasting twelve to twenty-four hours. In the four weeks prior to his hospitalization, he had almost constant episodes of stabbing pain which radiated to both sides and to his back. He also complained of alternating diarrhea and constipation and a weight loss of twenty pounds.

The physical examination was essentially negative except for prominent telangiectasia and erythema of the bridge of the nose and cheeks. The cutaneous lesions strikingly simulated rosacea. The liver was palpable 3 cm. below the rib margin.

The only abnormal laboratory findings were 35 per cent retention of bromsulphthalein in the blood in sixty minutes and 1+ reaction with quaiac in a sample of stool. A barium enema showed several small diverticuli in the sigmoid portion of the colon. A roentgenogram of the abdomen with the patient upright showed many distended loops of small bowel with gas and fluid in some loops, suggesting a probable obstruction. Subsequent roentgenograms four days later showed essentially the same findings.

An exploratory laparotomy was performed. The cecum and colon were normal but the distal ileum and adjacent mesentery were matted and necrotic. The surface of the liver was studded with numerous firm yellow nodules ½ cm. to 2 cm. in size. The pathologist reported a carcinoid tumor with spread to the mesentery and metastases to the liver.

Following the operation telangiectasia of the face, which had become increasingly more evident while the patient was in the hospital, gradually disappeared and at the time of discharge was only slightly visible.

Summary

Abdominal complaints are usually the first manifestation of the carcinoid syndrome. The cutaneous changes soon become prominent (flushing or telangiectasia). The cardiac signs may not appear until many years later. At present there is no effective treatment.

The cutaneous changes which occur in the carcinoid syndrome resemble rosacea. Gastrointestinal disturbances are also common in both of the disorders. Whether the dilated vessels in rosacea are related to an increased blood level of 5-hydroxy-tryptamine is questionable. In an attempt to evaluate the relationship of rosacea to increased blood levels of serotonin, urine samples from patients with rosacea are being studied to determine their content of 5-HIAA. A further report on this study will be forthcoming.

Endocrinopathies in Childhood

VINCENT C. KELLEY, M.D., Ph.D.
Salt Lake City, Utah

BOTH hyperfunction and hypofunction of every endocrine gland *can* and *do* occur in children. Likewise, practically every tumor of endocrine tissue, either benign or malignant, which occurs in adults also occurs in children. Many of these are encountered less frequently in children than in adults, but conversely some of them occur with considerably greater frequency in childhood. Certain endocrinopathies of relatively frequent occurrence in childhood are seen rarely, if ever, in adult patients.

Because of the magnitude of the subject of endocrinopathies in childhood, no attempt will be made to discuss it completely; rather, emphasis will be placed upon outlining a practical approach for the clinician to the evaluation of important endocrine problems in children. This discussion will be confined to a consideration of those endocrine disorders which occur only, or with greatest frequency, in the very young, those in which definitive diagnosis at the earliest possible moment is of great urgency, and those concerning which there are common and important misconceptions among the medical profession.

In this age we all are attempting to practice "scientific medicine." What has been called the "art" of medicine is giving way to what has been called the "science" of medicine. We must remember, though, that the "art" of medicine was practiced effectively only by those who focused on the problems they met a great deal of painstaking care, accurate observation, and *especially* intelligent, thoughtful evaluation. A similar approach is necessary in order effectively to practice the "science" of medicine. It is not necessarily true that the more laboratory procedures a physician orders the more scientific is his practice of medicine. Rather, the physician who is effectively practicing the science of medicine orders all of the laboratory procedures he needs which may be available to him, but orders each one only on

a specific indication. When the results are returned, he evaluates these in a careful and intelligent manner, remembering always that his measurements of height, weight, head circumference, pulse rate, blood pressure, et cetera, also represent precise data and must be given serious consideration in the overall evaluation of the patient. If the result of a certain laboratory procedure is not in conformity with his own observations, he must hold that result in question until he has reconfirmed it or must re-evaluate his thinking about the patient to determine whether or not that result actually does necessarily conflict with his own observations.

Laboratory data must be used only for what they are, i.e., tools to help in the evaluation of the patient. Any tool is only as effective as the man who is using it. The baseball bat in the hands of Mickey Mantle is a very effective tool, but in the hands of most of us it is only a long, cylindrical piece of wood. The scalpel in the hands of the surgeon is a very effective tool, but in the hands of Mickey Mantle it is only an over-sharpened butter knife. There are very many expensive and complicated laboratory procedures for evaluation of endocrine function; most of these are available only at certain referral centers and many of them are notorious for their unreliability. Therefore, in this field it becomes especially important for the clinician to have a thorough basic knowledge of fundamental principles and to develop to the utmost his clinical proficiency, thereby decreasing to a minimum the number of hormone assays and other laboratory procedures needed to verify or clarify his clinical impressions.

In the evaluation of laboratory data concerning the child suspected of having an abnormality of endocrine function one basic and well-known principle must always be remembered, i.e., that almost all biologic phenomena can be represented by the "normal distribution curve." But, do physicians remember this in the evaluation of patients, especially in the evaluation of laboratory data?

From the Department of Pediatrics, University of Utah College of Medicine, Salt Lake City, Utah.
Presented at the annual meeting of the Minnesota State Medical Association, Saint Paul, May 15, 1957.

TABLE I. EVIDENCES OF ENDOCRINE ABNORMALITIES
IN CHILDREN

1. Accelerated or retarded somatic growth
2. Accelerated or retarded bone age
3. Accelerated or retarded sexual development
4. Retarded mental development
5. Specific findings characteristic of individual endocrine abnormalities.

For example, as applied to endocrinopathies in childhood, regardless of which objective criteria are being studied—whether it be height, weight, bone age, occipito-frontal circumference, pulse rate, intelligence, serum calcium, protein-bound iodine, urinary 17-ketosteroids, the age at appearance of sexual hair, the histologic findings on testicular biopsy, the age at onset of menses, or the results of an insulin response test—the data must be evaluated in terms of the principle illustrated by this curve. If a large enough series of individuals is studied with regard to any one of these criteria, the results will be found to distribute themselves around a mean in accordance with the mathematical expression corresponding to this curve. Just a moment's reflection upon this fact makes it apparent that it is utterly impossible—and most unscientific to attempt—to state precisely the upper or the lower limit of "normal" for any given measurement. However, one can state quite precisely what the chances are that a given value would occur in a random sampling of the population at large. The laboratory has no right to report a value as "abnormally low (or high)"; rather the report should state "the chances are such and such that this value is abnormal."

Hypofunction and hyperfunction of endocrine glands are not all-or-none phenomena. As one would expect, it is much more common to obtain data indicating "borderline" function than it is to obtain data indicating almost certain abnormality. The physician is not being any more scientific if he concludes that all patients with these "borderline" values are normal than he is if he concludes that they all have endocrine abnormality. The physician's stock-in-trade is his *educated brain*. The reason the patient does not go directly to the commercial laboratory, have a battery of tests done, and be handed a slip of paper stating his diagnosis is that it is presupposed the physician will *think* about the laboratory results and evaluate them in relationship to the mass of other information about the patient which he has available.

Clinical Evidence of Endocrine Abnormalities in Children

How then does one suspect the existence of an endocrine disorder in a child? As shown in Table I, the early indications in children are considerably different than in adults. The child is a developing organism and the rate and sequence of his development are to a considerable extent under endocrine control. Accordingly, in a great many instances, the first clinical evidences of endocrine abnormality are those provided by abnormalities in the child's development. These include delay in mental development and delay or acceleration of somatic growth, epiphyseal maturation, and sexual development. The last three of these—somatic growth, epiphyseal maturation, and sexual development—are intimately inter-related. Quite commonly in any situation in which there is acceleration or delay of one of these, there is a similar deviation of the others from the expected developmental pattern. On the other hand, mental development does not appear to bear such an intimate relationship to any of these. Mental retardation is quite commonly found in association with severe impairment of development in somatic growth, epiphyseal maturation, and sexual maturation, but frequently occurs in the absence of these latter; and conversely, the latter frequently occur in the absence of mental retardation. Also, patients with advanced physical maturation seldom have correspondingly advanced mental development.

Of course, alterations in developmental patterns require at least months and usually years to manifest themselves clearly. Often it is possible and even quite urgent to diagnose endocrine abnormalities in children before time enough has elapsed to permit definitive alteration in developmental patterns. For example, the child with diabetes mellitus often presents himself to the physician in acidosis and coma as the initial manifestation of his disease. In retrospect, there may have been some mild preceding symptoms, but none alarming enough to have prompted the parents to consult the physician. In the converse situation, the child with hypoglycemia may be brought to the physician for the first time during or following a convulsion or loss of consciousness due to hypoglycemia. The child with a pheochromocytoma well may have and usually does have such severe symptoms that the diagnosis is made or death ensues before there has been

time for his disease to be reflected in his developmental pattern. This observation is equally true of the child, and especially the infant, with adrenal insufficiency. As will be mentioned later, the female with congenital adrenal hyperplasia should be recognized at birth by the alert physician. Unfortunately, this diagnosis usually is not made, and these patients who are female pseudohermaphrodites are considered to be males with hypospadias and cryptorchidism until many months or even a few years have elapsed, when they begin to show obvious signs of advanced development in somatic growth and sexual and epiphyseal maturation. At this time, the embarrassed doctor must confront the parents with the catastrophic announcement that the child is really a girl and that they now are faced with the dilemma of either changing the child's sexual role or permitting her to continue through life as a grossly abnormal male.

A sound knowledge of the manifestations of specific endocrine disorders is mandatory for the diagnosis of such disorders in children, just as it is for diagnosis in adults. However, in evaluation of possible endocrine abnormalities in children, the clinician has at his command some additional and very valuable criteria which are of little value in adults. Somatic, sexual and mental development can be evaluated with no "hocus-pocus" and with no complicated laboratory procedures. They require only careful observation on the part of the physician, a knowledge on his part of normal developmental patterns, and an alertness concerning the significance of deviations from these norms. A simple x-ray of the wrist and comparison of the film with standard tables of epiphyseal development will yield a reasonable estimate of bone age. If no specific findings characteristic of individual endocrine abnormalities and no gross abnormalities in somatic, sexual, epiphyseal, or mental development are observed, the chances of significant endocrine disorders existing are quite remote.

Mechanisms of Endocrine Homeostasis

The present concept of endocrine homeostasis is that this represents an extremely complicated process. As indicated in Figure 1, it appears that the central nervous system, probably the hypothalamus, is intimately involved in the regulation of all or nearly all of the endocrine glands. By some mechanism—and there still is some disagree-

ment as to whether these mechanisms are neural or humoral—the hypothalamus stimulates the pituitary, the heretofore so-called "master-gland," to secrete its appropriate tropic hormone. This

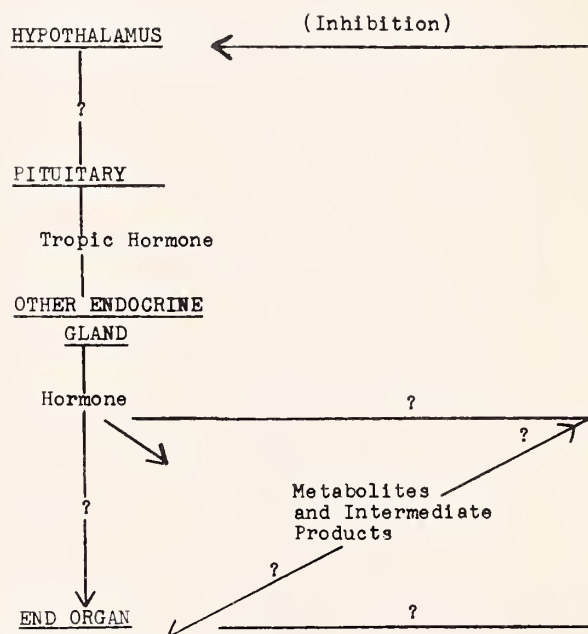

Fig. 1. General scheme for endocrine homeostasis.

hormone in turn stimulates the corresponding endocrine gland to produce its hormone or hormones. In view of recent studies, there now appears to be a strong likelihood that all endocrine glands produce more than one physiologically active substance, and consequently that the field of endocrinology is even much more complicated than previously it was thought to be. The hormone secreted by each gland is in turn metabolized to a variety of intermediates and end-products; the hormone itself as well as any of these derivatives may influence various end-organs or tissues. Two active compounds produced by one gland may be similar or antagonistic in the tissue response which they elicit.

Homeostasis is achieved by virtue of the fact that the products of each endocrine gland by some little understood mechanism are able to inhibit the release of additional hormone by that gland. In some instances, this may be accomplished by inhibition of the hypothalamus when some critical concentration of the hormone in the circulation is attained. In other instances, it appears that certain metabolites of the hormone are of key importance in producing inhibition; and in still other instances, the end-organ re-

-

sponse to the hormone produces physiologic effects, which in turn cause inhibition of release of that hormone and/or stimulation for the release of an antagonistic hormone.

In addition, there are known to exist certain inter-relationships among the hormones produced by different endocrine glands. For example, thyroid hormone is known to increase the rate of metabolism of adrenocorticosteroids. These steroids, in turn, are known to inhibit the production of thyroid hormone. Progesterone not only is the principal hormone produced by the corpus luteum, but also is an intermediary product formed by the adrenal cortex in the process of steroidogenesis. In view of these and many other known direct interactions of the products of different endocrine glands, one no longer can think of the pituitary as *the* master gland in the classic sense. To some extent, in all probability, the function of each endocrine gland affects the function of every other endocrine gland.

Causes of Delayed Somatic, Sexual, and Epiphyseal Maturation

Table II shows a classification of the causes of delayed somatic growth and sexual and epiphyseal maturation. The hypothalamus may be the site of the basic abnormality. This is commonly assumed to be the mechanism of the delayed maturation seen in such syndromes as Froehlich's Syndrome and the Laurence-Moon-Biedl syndrome.

Specific endocrine abnormalities are responsible in certain endocrinopathies. Pituitary abnormalities classically are considered to play an important role in producing delayed maturation. Without doubt, in those patients with generalized pituitary deficiency there results a delay in somatic, sexual and epiphyseal maturation. The pituitary dwarf is a real entity, but this diagnosis is one which is made much too frequently and is not justified unless there is evidence of generalized pituitary deficiency, including hypofunction of the adrenal and thyroid glands as well as evidence of delayed growth and maturation. Whether or not a specific growth hormonal deficiency exists in many

so-called pituitary dwarfs is a moot question and must remain so until a satisfactory assay for growth hormone is devised. At the present time, although this is assumed by many to be a common cause of growth failure, there is little direct evidence to support this concept.

Either hyperfunction or hypofunction of the thyroid, the adrenal or the pancreas may cause delayed growth and maturation. Classically, this effect has been considered to be produced by inhibition of the pituitary. In the entire field of pediatric endocrinology, one of the most common misconceptions among physicians is that hypothyroidism is a common cause of delayed growth and maturation in the young child. Certainly, most hypothyroid children have delayed growth and retarded bone age, but only a relatively small proportion of children with these findings have hypothyroidism. This diagnosis should never be made on the sole basis of retarded growth and bone age development in the absence of the other characteristic clinical manifestations and/or laboratory confirmation.

Abnormal metabolism of hormones, after their formation, may result in a failure to produce effective stimulation of the end-organ and therefore may result in delayed maturation.

Abnormal end-organ response may be the cause of delayed maturation. The classic example of this is the "Seabright-Bantam Syndrome" or pseudohypoparathyroidism, which occurs because of insensitivity of the end-organ response to parathyroid hormone.

Chronic disease—whatever the type—is a common cause of developmental retardation. The responsible mechanism in this instance usually is considered to be secondary pituitary inhibition. Whether or not this is a justifiable interpretation is open to question.

Hypogonadism*

This is a diagnosis that seldom should be made in a child. Actually, all children have hypogonadism until the onset of pubescence. The age at the onset of pubertal changes may vary quite extremely, occurring as late as the twenty-second year, in individuals who eventually mature into normal adults. For this reason it is extremely difficult to decide at what age to institute en-

*In preparing this and subsequent sections concerning abnormal sexual maturation, the author has followed closely the classification presented by Wilkins.¹

docrine therapy in an attempt to hasten sexual and somatic maturation. This often can be accomplished, but whether or not it should be undertaken is a question that must be decided in each individual patient on the basis not only of physical but also of emotional and psychiatric aspects of the case. For the small, underdeveloped 'teen age boy who is emotionally maladjusted because of his slow development, there is little consolation in the statement that he eventually will mature into a normal adult. Even though he does eventually mature normally with regard to sexual and somatic development the delay in this maturation well may have left permanent emotional scars which prevent him from ever becoming an entirely normal person.

Neurogenic causes of sexual infantilism in the male and female are manifest in both the Froehlich's syndrome and the Laurence-Moon-Biedl syndrome. Both of these syndromes are characterized by obesity and stunted growth. *Pituitary causes of sexual infantilism* are the same in both sexes, and include panhypopituitarism, specific growth hormone deficiency, and specific gonadotropic deficiency. Panhypopituitary dwarfs and those patients with specific growth hormone deficiency have stunted growth. Patients with specific gonadotropic deficiency may be normal in stature or may be tall and eunuchoid. *Gonadal causes of sexual infantilism* are those that have to do with failure of the gonads to develop, i.e., gonadal dysgenesis (or the so-called Turner's syndrome), testicular dysgenesis, and arrested development of the ovary. In these conditions, growth is stunted, but usually the features are mature and epiphyseal development is normal. Prepubertal castration in either sex results in tall, eunuchoid stature. Degeneration of gonads from trauma, disease, x-ray irradiation, et cetera, in either sex results either in normal or in tall, eunuchoid stature, depending upon the age at which the degeneration occurred. In the male, gynecomastia may be present in association with the Klinefelter syndrome or other conditions with testicular degeneration.

In general, urinary follicular stimulating hormone (F.S.H.) are low in those individuals with hypogonadism based on hypothalamic or pituitary abnormalities, and elevated in those whose primary site of abnormality is gonadal. However, it must be remembered that F.S.H. usually is not detectable in children before the age of puberty,

and therefore this determination is of no value in the young child and of little worth in any person in the pediatric age range unless a high excretion value is observed.

The importance of testicular biopsy in the differential diagnosis of male hypogonadism should be emphasized. In patients with primary pituitary lesions, testicular biopsy reveals simply an immature prepubertal testis. On the other hand, in testicular dysgenesis of the del Castillo type both Sertoli cells and Leydig cells are present but germinal epithelium is absent and the tubules are composed of Sertoli cells only. In the Klinefelter syndrome the tubules are hyalinized and neither germinal epithelium nor Sertoli cells are present. In castration, of course, whether due to absence or atrophy of testes, the Leydig cells are absent, along with the germinal epithelium and Sertoli cells. Testicular biopsy is the one most useful diagnostic procedure in the adult or older child. It is of little or no value, however, in the young child.

All of these categories of patients have very small testes and azospermia. As mentioned before, F.S.H. is low in those with primary pituitary lesions and elevated in those with primary gonadal lesions. Androgenic manifestations approximate normal in those patients with no or little involvement of Leydig cells. Urinary 17-ketosteroids in large part reflect adrenal function as well as testicular. Therefore, they are very low in the patients with primary pituitary lesions and, at most, moderately reduced in those with primary gonadal lesions. If Leydig cells are intact, 17-ketosteroids well may be normal in patients with testicular pathology, that is, in testicular dysgenesis of del Castillo and in Klinefelter's syndrome. Gynecomastia may occur either in Klinefelter's syndrome or in castrates, but is not a consistent finding in either.

Sexual Precocity in Females

Sexual precocity in females may be neurogenic, idiopathic, or gonadal in origin. In Wilkin's series,¹ 70 per cent were idiopathic in type. Of the remainder, half were neurogenic and half gonadal in origin. Both neurogenic and idiopathic types apparently result from early activation of the pituitary to stimulate the development of sexual maturation in the usual manner. Thus, the ovaries mature normally, ovulation may occur, and sex hormones are excreted in normal

adolescent amounts. Many types of neurogenic lesions have been implicated: some brain tumors, encephalitis, congenital defects of the hypothalamus, and Albright's syndrome (polyostotic fibrous dysplasia), which is characterized by fibrous areas of decreased density in the long bones and advanced sexual maturation. It seems important to emphasize that only 15 per cent of all cases of advanced sexual maturation in the female are due to ovarian tumors and that these patients, in contrast to those with central lesions, do not progress in an orderly fashion through the usual stages of maturation, but rather have rapid and spotty manifestations of advanced sexual development. One other cause of symptoms of advanced sexual maturation in the female, which occurs more frequently than one might expect, is the ingestion of estrogens. In these children the areola of the breast becomes heavily pigmented, there is a sudden growth of pubic hair, and bleeding may occur in rapid succession. This series of events may prove extremely frightening to the parents until its cause is determined.

Sexual Precocity in Males

Sexual precocity in males may be neurogenic, idiopathic, gonadal, or adrenal in origin. Neurogenic and idiopathic types, as in the female, lead to an orderly pattern of sexual development on an accelerated schedule. The testes mature normally, spermatogenesis may occur, and male sex hormones are excreted in normal adolescent amounts. Gonadal pathology causes only 5 per cent of all cases of advanced sexual development in the male. As these tumors usually involve only one testis, with the other being immature or atrophic, careful physical examination often may lead to a correct clinical diagnosis. Spermatogenesis does not occur, but sex hormones are excreted in excessive amounts.

Advanced sexual maturation of adrenal origin in the male may be due to tumor or to adren-

al hyperplasia. In either case, the testes are usually small and immature, there is no spermatogenesis, and androgens are excreted in excessive amounts. In those patients with adrenal hyperplasia, adrenal insufficiency often may be evident.

Heterosexual Development

The types of heterosexual development may be considered to be two: (1) sex reversal, or (2) intersex. *Sex reversal* in the female occurs with congenital adrenal hyperplasia which has its onset during embryonic life. These patients are female pseudohermaphrodites. They have ovaries and complete or partial female internal sexual structures, but the external appearance of males with a urogenital sinus and enlarged phallus. These patients exhibit excessive growth, increased bone age, precocious development of sexual hair, increased 17-ketosteroid excretion, and the early development of male secondary sexual characteristics.

In those female patients with adrenal tumor, arrhenoblastoma, or adrenal hyperplasia with its onset after birth, *virilism* results. The phallus enlarges and 17-ketosteroid excretion increases. If they are young enough at the time of onset, they exhibit excessive growth, increased bone age and precocious development of sexual hair.

Sex reversal occurs also in the male with a feminizing adrenal tumor. At the time of birth these patients have no abnormality, but later they develop feminization often with considerable gynecomastia. They do not have excessive growth, increased bone age, precocious sexual hair, or increased 17-ketosteroid excretion.

True intersexes may be true hermaphrodites or male pseudohermaphrodites. The true hermaphrodites are those with mixed gonads—either one ovary and one testis or with one or each gonad being an ovo-testis. Male pseudohermaphrodites have external features of females but their gonads are testes. Neither of these groups of patients have excessively rapid growth and maturation or increased 17-ketosteroid excretion. Female pseudohermaphrodites, other than patients with congenital adrenal hyperplasia, are extremely rare.

Influence of Adrenal Function on Sexual Development

Table III summarizes several ways—all of which have been mentioned earlier—in which abnormal adrenal function may influence sexual maturation. Delayed sexual maturation may result from either

chronic adrenal insufficiency or chronic overproduction of adrenal steroids of the 17-hydroxycorticosteroid type such as occurs in Cushing's syndrome. Advanced sexual maturation may result

Fig. 2. Genitalia in female pseudohermaphroditism: (a) before plastic repair; (b) after plastic repair.

either from tumor or hyperplasia of the adrenal. Tumors may be either virilizing or feminizing and may cause either isosexual or heterosexual development.

Adrenal hyperplasia in the female produces pseudohermaphroditism if present by the third to fifth fetal month. If it occurs later or after birth, it produces virilism. Adrenal hyperplasia in the male produces the syndrome known as macrogenitosomia precox, which consists of advanced growth and sexual development according to an isosexual pattern. With adrenal hyperplasia in both males and females there is early masculinization, excessively rapid somatic growth, and accelerated epiphyseal maturation. However, because of the accelerated epiphyseal maturation, growth ceases at an early age and in many cases the patient becomes a somewhat stunted adult.

The typical appearance of the female pseudohermaphrodite with enlarged chordee phallus, and urogenital sinus is illustrated in Figure 2a. This appearance of the external genitalia is pathognomonic of congenital adrenal hyperplasia and permits the diagnosis of this condition at birth. Furthermore, when this typical anatomic configuration is present, one need not be concerned about adrenal tumor, since these have not been reported to occur as early as the third to fifth fetal month as would be necessary to cause this developmental anomaly. Figure 2b shows the excellent result of plastic repair in the female—

TABLE IV. PITUITARY-ADRENAL HORMONE PATTERNS IN CONGENITAL ADRENAL HYPERPLASIA

Hormone Type	Pre-Therapy	During Cortisone Therapy
17-ketosteroid (Urine)	High	Normal
17-hydroxycorticosteroids (Urine) (Plasma)	Low Low	Normal Normal
ACTH (Blood)	High	Normal

one year after operation. This plastic repair is a simple operation which should be done as early as possible and usually can be accomplished as a one-step surgical procedure.

Biochemical Abnormality in Congenital Adrenal Hyperplasia

Table IV shows typical hormone patterns in untreated patients with congenital adrenal hyperplasia and the influence of cortisone therapy on these patterns.² It long has been known that patients with congenital adrenal hyperplasia produce excessive amounts of 17-ketosteroids. This formerly was interpreted as an indication of generalized hyperfunction of the adrenal cortex. Quite the opposite, however, is true; these patients have a segmental adrenal insufficiency and are unable to produce normal amounts of 17-hydroxycorticosteroids. This latter group of steroids includes compound F, the major steroid produced by the normal human adrenal cortex. Homeostasis of adrenal function is dependent upon the intermittent inhibition of pituitary release of ACTH; this results when blood concentrations of 17-hydroxycorticosteroids attain some critical level. In patients who cannot produce 17-hydroxycorticosteroids in a normal manner, inhibition fails to occur and ACTH is overproduced. This in turn causes overstimulation of the adrenal cortex and overproduction of 17-ketosteroids, as well as histologic hyperplasia of the cortex. As shown in the pretherapy column, blood ACTH levels and urinary 17-ketosteroid excretion are high, but both plasma and urinary 17-hydroxycorticosteroids are extremely low. During therapy with cortisone, this pattern reverts to normal, since cortisone is a 17-hydroxycorticosteroid and furnishes ideal substitution therapy.

The biochemical abnormality of the adrenal cortex in patients with congenital adrenal hyperplasia has been defined clearly in recent years. Figure 3 shows a simplified representation of the

chemical steps involved in steroidogenesis by the adrenal cortex.^{3,4} Compound F (17-hydroxycorticosterone) and compound B (corticosterone) are the principal end-products of steroidogenesis

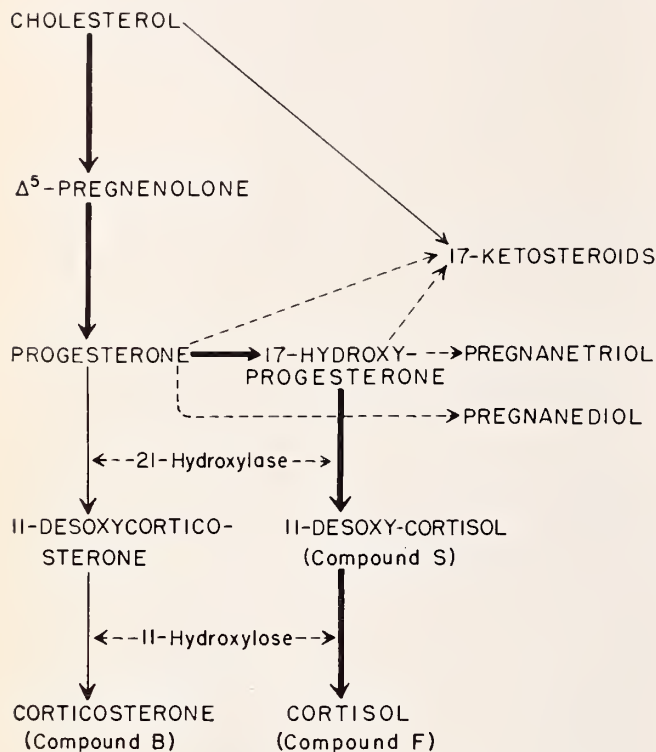

Fig. 3. Steroidogenesis by the adrenal cortex. Heavy arrows show the usual principal pathway. Solid lighter arrows show usual secondary pathways. Dotted arrows show alternate pathways which are insignificant in normal subjects. In congenital adrenal hyperplasia, 21-hydroxylase is absent or greatly reduced in quantity thus blocking conversion of progesterone to 11-desoxycorticosterone and 17-hydroxyprogesterone to 11-desoxycortisol and causing increased production of 17-ketosteroids, pregnanediol, and pregnanetriol. In hypertensive type 11-hydroxylase is affected rather than 21-hydroxylase, thus preventing formation of compounds B and F and increasing the end-products of the alternative pathways.

in the normal individual. Among the other end-products of steroidogenesis are the 17-ketosteroids and insignificant amounts of pregnanediol and pregnanetriol.

In patients with congenital adrenal hyperplasia the basic abnormality consists of a deficiency of certain hydroxylating enzymes necessary for the process of steroidogenesis. This deficiency ordinarily is in the 21-hydroxylating enzyme but in occasional patients (hypertensive type) may be in the 11-hydroxylating enzyme.⁵ Because of this enzymatic block the principal end-products of steroidogenesis are the 17-ketosteroids, pregnanediol, and pregnanetriol (or compound S in the hypertensive type) rather than compound F and compound B as in the normal.

TABLE V. LABORATORY DIFFERENTIATION: ADRENAL TUMOR VS. HYPERPLASIA

	Hyperplasia	Tumor
Plasma 17-OHCS	Low	Normal or high
Urinary 17-OHCS	Low	Normal or high
Urinary Beta 17-ketosteroids	Moderate	High
Urinary pregnanediol and pregnanetriol	High	Normal
Plasma 17-OHCS-ACTH response	No change	Increase
Pregnanediol-pregnanetriol ACTH	Large increase	Slight increase
17-keto response to cortisone	Decrease	No change

Because of this enzymatic abnormality, it is possible to make a positive laboratory differentiation between congenital adrenal hyperplasia and adrenal tumor, since patients with tumor do not have similar enzymatic deficiency. As shown in Table V, plasma and urinary 17-hydroxycorticosteroids are low in patients with congenital adrenal hyperplasia and normal or high in patients with adrenal tumor. Urinary beta-17-ketosteroids are moderately elevated in congenital adrenal hyperplasia patients and very high in adrenal tumor patients. Although this is one of the oldest and best-known differential tests, it is the least reliable of those shown in this table. Urinary pregnanediol and pregnanetriol are high in patients with congenital adrenal hyperplasia and normal in patients with adrenal tumor. In response to ACTH stimulation, the plasma 17-hydroxycorticosteroids do not increase appreciably in patients with congenital adrenal hyperplasia but increase normally or excessively in patients with adrenal tumor. Conversely, pregnanediol and pregnanetriol increase excessively in response to ACTH in patients with congenital adrenal hyperplasia but only slightly in patients with adrenal tumor. Finally, the urinary 17-ketosteroids decrease remarkably following cortisone administration for a period of several days in patients with congenital adrenal hyperplasia but not in patients with adrenal tumor.

Endocrine Conditions in Which Diagnosis Is Urgent

Table VI shows a group of endocrine conditions in children in which it is urgent to make the diagnosis at the earliest possible time. These

TABLE VI. URGENT ENDOCRINE DIAGNOSES

Diagnosis	Reason
1. Diabetes mellitus	Imminent death
2. Diabetes insipidus	" "
3. Acute adrenal insufficiency	" "
4. Pheochromocytoma	" "
5. Hypoglycemia	Brain damage and mental retardation
6. Hypothyroidism in infant	" " "
7. Advanced sexual maturation	(a) Danger of malignancy (b) Psychologic implications
8. Heterosexuality	Psychologic implications
9. Congenital adrenal hyperplasia in newborn	(a) Imminent death from dehydration (b) <i>In female:</i> Danger of unnecessary psychologic trauma and family hardship if error made in determination of sex at birth.

include diabetes mellitus, diabetes insipidus, acute adrenal insufficiency and pheochromocytoma, which often may not be discovered until the patient is in imminent danger of death. Hypoglycemia and hypothyroidism in the young infant are diagnoses which must be made as early as possible because, if allowed to remain untreated, they commonly cause brain damage and mental retardation which is irreversible. Conditions causing advanced sexual maturation must be diagnosed as early as possible because of the danger of malignancy and because of the psychologic implications in these conditions. Similar considerations make it necessary to diagnose as early as possible patients with heterosexuality. If the sexual role of such patients must be altered by surgical intervention, this should be done at as young an age as possible because of the psychologic trauma that almost inevitably results in the older child. Congenital adrenal hyperplasia can be diagnosed in the newborn, and this may be a very urgent diagnosis. In either sex, the patient may be in imminent danger of death from dehydration and adrenal insufficiency. In the female, especially, the diagnosis nearly always should be possible at the time of birth because of the characteristic appearance of the external genitalia. It is important that this diagnosis be made because of the unnecessary psychologic trauma to the patient and hardship for the family if an error is made in the determination of the sex at the time of birth.

Endocrine Diagnoses Too Frequently Made

Table VII indicates some endocrine diagnoses which are made too frequently without proper substantiation. Hypothyroidism in the infant is

TABLE VII. ENDOCRINE DIAGNOSES TOO FREQUENTLY MADE

1. Hypothyroidism
2. Pituitary Dwarfism
3. Hypogonadism
4. Froehlich's Syndrome
5. Cushing's Syndrome

a relatively rare condition. All too frequently this diagnosis is made and thyroid therapy instituted in infants who have only mental retardation or delayed somatic or epiphyseal development. Such patients deserve intensive diagnostic study since many of them may have conditions which are amenable to therapy, such as hypoglycemia, phenylketonuria, etc. The initiation of thyroid therapy in such patients accomplishes nothing and frequently causes such a prolonged delay in establishing the proper diagnosis that irreparable brain damage has resulted to the patient in the interim. In this regard, it should be remembered that a basal metabolic rate test is virtually of no value in infants and young children. The diagnosis of hypothyroidism in this age group, or in any child for that matter, should not be made in the absence of confirmatory laboratory evidence of a more specific nature.

As mentioned earlier, pituitary dwarfism and hypogonadism are diagnoses that are extremely hard to verify in the child and are made much too often. Both Froehlich's and Cushing's syndromes are rare but these diagnoses often are considered and all too frequently made without adequate substantiation.

Summary

It has been impossible in this brief presentation to discuss in great detail the subject of endocrinopathies in childhood. An attempt, therefore, has been made to stress a practical approach to the consideration of these conditions and to emphasize how rewarding careful and repeated physical examination and observation of the patient may be in their evaluation. Finally, although definitive diagnosis in endocrine conditions in childhood often may be dependent upon laboratory evaluation, laboratory results alone may be quite misleading unless one is extremely careful in his interpretation of them; if maximum information has been gleaned from the history and physical examination, the number of laboratory examinations required may be kept at a minimum.

Hypercalcemia in Hyperthyroidism

Review and Report of Four Cases

M. PIERRE KOENIG, M.D.

DONALD A. SCHOLZ, M.D.

ROBERT M. SALASSA, M.D.

Rochester, Minnesota

SIGNIFICANT changes in metabolism of calcium and demineralization and deformities of the skeleton may occur in patients with hyperthyroidism. Since the initial report by Kummer¹ in 1917, numerous publications²⁻⁴ have appeared in which roentgenographic evidence of skeletal changes in patients with hyperthyroidism are described, yet the underlying factors responsible for these changes remain obscure. While the concentrations of calcium and inorganic phosphorus in the serum are usually normal in hyperthyroidism, hypercalcemia and hypercalciuria may occur.

Several cases of severe hyperthyroidism have been reported^{5,6} wherein a clinical course of loss of weight, tachycardia, nausea, vomiting, muscular weakness and fever was associated with hypercalcemia and hypercalciuria. Diagnoses of both primary hyperparathyroidism and hyperthyroidism were considered in these cases, but after the patients were treated for hyperthyroidism they showed marked clinical improvement and the abnormal values for serum calcium returned to normal. The possible coexistence of hyperthyroidism and hyperparathyroidism must be considered in such cases, since at least six cases⁷⁻¹¹ (Table I) had been reported in which both diseases were present. Ball,¹² Hellström¹³ and Meyer-Borstel¹⁴ have each reported a case in which the patient had elevation of the basal metabolic rate, hypercalcemia, and skeletal changes compatible with osteitis fibrosa cystica; but the presence of a hyperfunctioning tumor or of diffuse hyperplasia of the parathyroid gland was not proved in any of the three cases. In Bergstrand's¹⁵ case, necropsy revealed diffuse hyperplasia of the parathyroids and enlargement of the thyroid gland; however, antemortem studies of blood calcium or phosphorus had not been made, although the basal metabolic rate had been elevated.

Dr. Koenig is a Fellow in Medicine, Mayo Foundation, Rochester, Minnesota.

Drs. Scholz and Salassa are in the Section of Medicine, Mayo Clinic and Mayo Foundation.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Our paper concerns observation of the calcium metabolism in four cases of hyperthyroidism with hypercalcemia and one case of coexisting hyperthyroidism and primary hyperparathyroidism encountered at the Mayo Clinic during the past six years.

Methods

The serum calcium was determined by employing oxalate precipitation and permanganate titration. Values cited in many texts for the normal range of serum calcium are usually 9 to 11 mg. per 100 ml. The mean value for serum calcium in 109 healthy adults in our laboratory by this method was 9.77 mg. per 100 ml. with a standard deviation of 0.31 mg. per 100 ml. The "normal range" including 95 per cent of the normal population so described is 9.2 to 10.4 mg. per 100 ml. The error of the method as indicated by replication is 0.01 mg. per 100 ml.¹⁶ The serum inorganic phosphorus was determined by the method of Gomori.¹⁷

Quantitative studies of the urinary excretion of calcium were made with the patients eating a diet containing 135 mg. of calcium daily. The calcium in the urine was measured by means of precipitation of calcium as oxalate followed by conversion of oxalate to carbonate and acidometric titration of the calcium carbonate so formed. The intravenous calcium-loading test was carried out by the method described by Nordin.¹⁸

Report of Cases

Case 1.—A thirty-seven-year-old white man came to the clinic in January, 1956, complaining of persistent tachycardia and abnormal fatigue of two months' duration. He had been aware of mild intolerance to heat and increased sweating and tachycardia for six months. Tremor of the hands, exophthalmos, or goiter had not been noted. Two episodes of left renal colic had occurred, one in 1949 and one in 1952. Renal calculi had never been passed.

Physical examination revealed a moderately stimulated man with a fine tremor of the outstretched fingers and a radial pulse rate of 120 beats per minute. The blood pressure was 160 mm. of mercury systolic and

TABLE I. REPORTED CASES OF HYPERTHYROIDISM WITH COEXISTING HYPERPARATHYROIDISM

Author	Cases	Basal Metabolic Rate Per Cent	Blood Values (Milligrams Per 100 cc. of Serum)		Roentgenographic Findings	Surgical Findings
			Calcium	Phosphorus		
Ballin and Morse ⁷	1	+27	15.4	1.7	Osteoporosis of spinal column	Two parathyroid adenomas; no mention of thyroid findings—calcified adenoma of thyroid previously removed.
Cooley ⁸	1	+23	13.6 15.2	2.6 3.0	Extensive skeletal demineralization and formation of cysts	Cystic parathyroid tumor; small colloid goiter.
Miller and Evans ⁹	1	+29 +36	17.2	2.5	Slight osteoporosis of skull and femur	Parathyroid adenoma; subtotal thyroidectomy—53 gm. of hyperplastic tissue removed.
Noble and Borg ¹⁰	1	+38 +43	15.0 14.5	2.4 2.6	Extensive osteitis fibrosa	Cystic clear-cell parathyroid adenoma, retromanubrial in location; subtotal thyroidectomy—lymphocytic infiltration without hyperplasia.
Chapman and Maloof ¹¹	2		No data			

94 mm. diastolic. The thyroid gland was symmetrically enlarged, rather firm, and weighed about 25 gm. Moderate weakness of the quadriceps muscles was demonstrable. The results of examination were otherwise normal.

Pertinent laboratory studies revealed initial values per 100 cc. of serum as follows: 11 mg. of calcium, 2.7 mg. of inorganic phosphorus, 10 King-Armstrong units of alkaline phosphatase, and 6.6 gm. of proteins with 4.0 gm. of albumin and 2.6 gm. of globulin. The value for blood urea was 28 mg. per 100 cc. Repeated determinations of serum calcium gave values of 10.2 and 10.8 mg. per 100 cc. with corresponding values for inorganic phosphorus of 2.9 and 3.2 mg. Roentgenograms of the thorax, kidneys, ureters and bladder did not show evidence of any abnormality. The basal metabolic rate was +18 per cent and protein-bound iodine measured 10.2 micrograms per 100 cc. of serum. A radioiodine tracer revealed 41 per cent uptake in the thyroid in six hours and 53 per cent in twenty-four hours, with a thyroïdal clearance of 42 cc. per minute. Specimens of urine collected over a twenty-four-hour period, with the patient eating a diet containing 135 mg. of calcium, revealed 258, 267 and 319 mg. of calcium on three consecutive days. A calcium-loading test revealed a decrease of 79 per cent in the excretion of phosphorus following the intravenous infusion of calcium.

The patient requested treatment with radioiodine due to a profound fear of surgical procedures. The normal results of the calcium-loading test were considered evidence against coexisting primary hyperparathyroidism. The patient received a therapeutic dose of 7.1 millicuries of I¹³¹ on February 9, 1956. A repeat radioiodine tracer in March, 1956, revealed practically no uptake by the thyroid gland, although the patient was still moderately toxic. The basal metabolic rate was now +29 per cent and the values for serum calcium and inorganic phosphorus were 10.7 mg. and 2.1 mg. per 100 cc. respectively. On April 18, he stated that he felt improved, and clinically he appeared less toxic. The basal metabolic rate was +13 per cent and the value for butanol extractable iodine was 8.9 micrograms per 100 cc. of serum. The value for calcium was 10.9 mg. per 100 cc. of serum and that for inorganic phosphorus was 2.9 mg.

The patient returned to the clinic in July, 1956, be-

cause of symptoms suggestive of early myxedema. On physical examination the clinical features of myxedema were present; the basal metabolic rate had fallen to -26 per cent, and the value for protein-bound iodine had decreased to 2.4 micrograms per 100 cc. of serum. The value for serum calcium was 10.3 mg. per 100 cc. and for inorganic phosphorus, 3.3 mg. His clinical response to 1½ grains of desiccated thyroid daily was excellent. In February, 1957, the basal metabolic rate was -9 per cent; calcium measured 10.2 mg. and inorganic phosphorus 3.0 mg. per 100 cc. of serum. Measurement of urinary excretion of calcium, with the patient eating a diet containing 135 mg. of calcium daily, revealed 168, 140 and 102 mg. of calcium in three specimens collected during consecutive twenty-four-hour periods. The slightly abnormal values for calcium excreted in the urine were not considered to be of diagnostic significance, especially in the presence of normal values for serum calcium.

Case 2.—A thirty-six-year-old white man came to the clinic in November, 1954, complaining of loss of appetite and recurrent episodes of nausea of several months' duration. In 1942, he had passed two renal calculi after treatment with sulfonamide drugs for an infection of the urinary tract. Another renal stone had been passed in 1943. Excretory urograms were reported normal at that time.

Physical examination revealed an obese man, whose blood pressure was 140 mm. of mercury systolic and 85 mm. diastolic. The sclerae were not icteric. Enlargement of the liver or spleen was not noted. The results of laboratory studies were normal, except for values for serum calcium of 10.8 and 10.5 mg. per 100 cc. The corresponding values for inorganic phosphorus were 4.4 and 4.2 mg. per 100 cc. of serum; the value for total proteins was 6.4 gm. per 100 cc. of serum with 3.9 gm. of albumin and 2.5 gm. of globulin. He was unable to stay for further studies of calcium metabolism and was dismissed on a 1500-calorie reduction diet. He returned in January, 1955, because of persistent nausea and recent polydipsia. He appeared stimulated and the radial pulse rate measured 106. The skin was warm, moist and velvety in texture. The thyroid gland was palpable and felt somewhat firmer than normal. The basal metabolic rate was +43 per cent. A radioiodine tracer revealed an *in vivo* uptake

within twenty-four hours of 44.8 per cent by the thyroid with a thyroidal clearance of 36 mm. per minute. The blood sugar measured 130 mg. per 100 cc.; the value for calcium was 11.2 mg. per 100 cc. of serum and that of inorganic phosphorus, 3.8 mg.

After preparation with Lugol's solution, surgical exploration was carried out on January 27, 1955. Right lobectomy with removal of the isthmus was performed because a papillary and follicular adenocarcinoma, grade 1, was found just beneath the capsule at the junction of the anterior and lateral borders of the right lobe. Subtotal left lobectomy also was performed. Histologically, the nonmalignant resected thyroid tissue was found to be hyperplastic. The two parathyroid glands on the right were completely devascularized during the course of the dissection. The right inferior gland was implanted into the right sternocleidomastoid muscle. The left inferior parathyroid was easily located, but the left superior gland could not be identified. Two days after operation the value for calcium was 9.9 mg. and that for phosphorus 3.6 mg., both per 100 cc. of serum. Prior to the patient's dismissal, calcium measured 9.6 mg. and inorganic phosphorus 4.4 mg. per 100 cc. of serum.

In March, 1955, symptoms associated with hypothyroidism developed. The basal metabolic rate was now -17 per cent. The patient was placed on a regimen of one grain of desiccated thyroid daily and ten drops of Lugol's solution three times a day. He returned in June of the same year and appeared to be clinically euthyroid, although he had gained twenty-one pounds. Minimal periorbital edema and bulbar chemosis were present bilaterally, but there was no lid retraction or lag.

In January, 1956, he returned because of progressive signs and symptoms of hyperophthalmopathic Grave's disease. The basal metabolic rate was -18 per cent and the value for serum calcium was 9.3 mg. per 100 cc. The dosage of desiccated thyroid was increased to two grains per day along with 10 drops of Lugol's solution three times a day. The ocular condition has remained essentially unchanged since this treatment was instituted.

Case 3.—A fifty-five-year-old man registered at the clinic in June, 1951, with a primary complaint of loss of weight, generalized weakness, marked irritability and heat intolerance of several months' duration. In April of the same year he was found to have mild diabetes mellitus. His history and the family history were non-contributory.

Physical examination revealed a well-developed man who showed evidence of recent loss of weight. A definite tremor of the outstretched fingers, warm, moist skin, and a radial pulse rate of 92 were noted. Blood pressure was 144 mm. of mercury systolic and 86 mm. diastolic. The thyroid gland was not enlarged but felt firmer than normal. The results of examination were otherwise normal.

The results of pertinent laboratory studies revealed 11.2 and 11.1 mg. of calcium and 4.0 mg. of inorganic phosphorus per 100 cc. of serum; fasting blood sugar measured 179 mg. per 100 cc. The basal metabolic rate was +32 per cent, and the value for protein-

bound iodine was 13.4 micrograms per 100 cc. of serum. A radioiodine tracer revealed 70 per cent uptake in the thyroid gland in twenty-four hours. The specific gravity of the urine was 1.011 and results of the Sulzowitch test were strongly positive. Roentgenograms of the thorax and skull and an excretory urogram did not show evidence of any abnormality.

The cause of the hypercalcemia was not clear. It was recognized that elevated concentration of calcium in the serum could be associated with untreated hyperthyroidism, but the diagnosis of coexisting primary hyperparathyroidism deserved consideration. It was decided to defer further studies of metabolism of calcium until the hyperthyroidism was controlled; a therapeutic dose of 6 millicuries of radioiodine was administered with this intention.

The patient returned in three months at which time he was found to be improved. The diabetes was under good control. He had gained ten pounds and showed fewer clinical signs of hyperthyroidism than on the previous visit. The basal metabolic rate was +9 per cent; fasting blood sugar measured 168 mg. per 100 cc. and cholesterol, 197 mg. per 100 cc. of plasma. Two values for calcium were 11 and 10.5 mg. per 100 cc. of serum with corresponding values for inorganic phosphorus of 3.0 and 3.1 mg. The value for serum alkaline phosphatase was 6.3 Bodansky units. Quantitative studies of the urinary excretion of calcium revealed 149, 138 and 174 mg. of calcium in specimens excreted during three consecutive twenty-four-hour periods, with the patient eating a diet containing 135 mg. of calcium per day. Again, surgical exploration of the neck for a parathyroid tumor was deferred.

In December, 1951, the home physician prescribed $\frac{3}{4}$ grain of desiccated thyroid daily because the patient's basal metabolic rate had dropped to -22 per cent. The patient returned to the clinic the following month at which time he appeared euthyroid. The basal metabolic rate was now -5 per cent. The values for serum calcium on two occasions were 9.8 and 9.6 mg. per 100 cc., with a corresponding value for inorganic phosphorus of 3.6 mg. The value for serum alkaline phosphatase had dropped to 4.4 Bodansky units. The patient was advised to continue taking $\frac{3}{4}$ grain of desiccated thyroid per day and was dismissed. He stopped taking the drug several months later, however, without subsequent development of any symptoms of hypothyroidism. During a routine check-up in 1955 he was found to be in good health. The diabetes was under good control. The basal metabolic rate was -7 per cent and the value for serum calcium was 9.6 mg.

Case 4.—A thirty-three-year-old woman was referred to the clinic on March 8, 1956, with a diagnosis of "toxic goiter." Her illness had started in December, 1955, when she noted generalized weakness, which was most pronounced in her legs, and a tremor of the hands. She subsequently became aware of intolerance to heat and felt "nervous." Enlargement of her neck was a recent development, but ocular symptoms had not become apparent. There was no history of renal calculi, polyuria or polydipsia.

Physical examination revealed a stimulated, restless woman whose skin was warm and moist. The blood pressure was 168 mm. of mercury systolic and 88 mm. diastolic. The radial pulse rate was 136 beats per minute. A fine tremor of the hands was obvious. Ocular examination revealed bilateral proptosis with stare and lid lag. Neither chemosis nor muscle palsy was evident. The thyroid gland was diffusely and symmetrically enlarged and weighed an estimated 30 gm. A bruit was audible over both lobes.

Laboratory studies revealed the following significant findings: 10.8 mg. of calcium, 2.8 mg. of inorganic phosphorus, 4.1 gm. of albumin and 1.9 gm. of globulin, all per 100 cc. of serum. The basal metabolic rate was +44. A roentgenogram of the thorax did not show evidence of any abnormality. Subtotal thyroidectomy was advised and the patient was given Lugol's solution in preparation for operation. On the day before operation, she was much less stimulated and the basal metabolic rate was +24. The value for serum calcium was 10.4 mg. and that for inorganic phosphorus was 2.5 mg. Subtotal thyroidectomy was performed on March 30, 1956, with the removal of 22 gm. of thyroid tissue which histologically showed diffuse parenchymal hypertrophy. All four parathyroid glands were identified grossly and appeared normal. Her recovery from the operation was uneventful. On June 2, 1956, the patient returned to the clinic. Clinical evidence of mild myxedema was present. The basal metabolic rate was -19 per cent; calcium measured 9.9 mg. and inorganic phosphorus measured 2.6 mg., each per 100 cc. of serum. Desiccated thyroid was prescribed because of the myxedema.

Case 5.—A sixty-year-old white woman came to the clinic in June, 1955, having a three months' history of exertional dyspnea and fatigue and recent episodes of tachycardia lasting up to thirty minutes. She had taken Lugol's solution for five days in April, 1955, without subjective improvement. Ocular symptoms had not been noted. Mild polydipsia and polyuria had developed in recent weeks. The history revealed that in 1948 transitory hemiparesis and dysarthria of four to five hours' duration had developed. Symptoms of duodenal ulcer had appeared in 1953, but discomfort from this source had abated after the use of a liberal ulcer diet and Gelusil. Her intake of milk was not excessive; absorbable alkalis were rarely used and she denied any intake of vitamin D.

Physical examination revealed a moderately stimulated woman weighing 150 pounds. Her blood pressure was 134 mm. of mercury systolic and 82 mm. diastolic; the radial pulse rate was 112 beats per minute. The thyroid gland was palpable, but not significantly enlarged. A nodule 1 cm. in diameter was palpable in the region of the left lobe of the thyroid. Complete neurologic evaluation failed to reveal any residuum from a previous "stroke."

Laboratory studies revealed the following pertinent data: 30 mg. of urea per 100 cc. of blood; 180 mg. of cholesterol per 100 cc. of plasma; 11.1 mg. of calcium, 3 mg. of inorganic phosphorus, 15.9 King-Armstrong units of alkaline phosphatase, 3.7 gm. of albu-

min and 2.0 gm. of globulin, all per 100 cc. of serum. Repeated evaluations for calcium and inorganic phosphorus showed values of 11.4 and 3.0 mg. respectively. Roentgenograms of the head and thorax did not show evidence of any abnormality, but roentgenograms of the upper portion of the gastrointestinal tract revealed evidence of a duodenal ulcer. The initial basal metabolic rate was +4 per cent, but the protein-bound iodine was 12.6 micrograms per 100 cc. of serum. A radioiodine tracer revealed 35 per cent uptake in the thyroid in six hours and 53 per cent uptake in twenty-four hours, with a thyroid clearance rate of 34 cc. per minute. Quantitative studies of urinary excretion of calcium with the patient on a diet containing 135 mg. of calcium daily revealed 335, 446, and 495 mg. in three specimens collected during consecutive twenty-four-hour periods.

Despite the minimal clinical evidence for hyperthyroidism the laboratory findings of elevation of the protein-bound iodine and increased avidity of the thyroid for iodine were considered significant. In view of the palpable nodule in the neck and the unlikely possibility that the patient's mild hyperthyroidism could be responsible for the hypercalciuria and hypercalcemia, surgical exploration of the neck was advised. On June 30, 1955, the surgeon identified and removed a typical parathyroid adenoma located in the usual position of the left superior gland. The nodule weighed 210 mg. and was a mixed cell type histologically. The other three parathyroid glands were identified grossly and appeared normal. Subtotal thyroidectomy with removal of 13 gm. of hyperplastic thyroid tissue was performed. Her postoperative course was uneventful. On the first day after operation the value for calcium was 9.0 mg. and that for inorganic phosphorus was 3.1 mg. per 100 cc. of serum. The basal metabolic rate was -10 per cent and the values for calcium and inorganic phosphorus were 9.7 and 3.6 mg., respectively, two weeks after operation.

Comment

The results of laboratory studies of thyroid function in the five cases reported herein (Table II) corroborated the clinical impression of hyperthyroidism. In Cases 1 and 2, the values for serum calcium and inorganic phosphorus were checked because of the patients' history of renal colic or passage of renal stones or both; in Case 5 the value for serum calcium was determined because of unexplained polyuria. In the other two patients, the values for these elements were obtained only because of academic interest. All five patients had hypercalcemia on the basis of values in our laboratory (normal values, 9.2 to 10.4 mg. of calcium per 100 cc. of serum). The alkaline phosphatase was elevated in two of the three patients so studied. Quantitative studies of urinary excretion of calcium in three patients revealed hypercalciuria in each patient.

†Per 100 cc. serum.

‡Coexisting hyperthyroidism and hyperparathyroidism.

As mentioned at the outset, the diagnoses of both hyperthyroidism and primary hyperparathyroidism received clinical consideration in each case; however, the fact that in the first four patients the values for serum calcium returned to normal concentrations after correction of the hyperthyroidism, and that in Case 1 the calcium loading test gave normal results indicated that hypercalcemia was secondary to hyperthyroidism. Exploration for a parathyroid tumor was advised in the fifth patient because of the palpable nodule in the neck and the rather unlikely possibility that hypercalcemia and hypercalciuria could be attributed to mild hyperthyroidism. In Case 2, the effect on calcium metabolism of the unavoidable devascularization of the two parathyroid glands is difficult to evaluate. Tetany did not develop during the postoperative period. Values for serum calcium remained normal, which would seem unlikely if a parathyroid tumor was present in the unidentified gland.

The mechanism responsible for the disturbance of calcium metabolism which may occur in hyperthyroidism remains unsolved. In 1929, Aub and co-workers¹⁹ demonstrated that urinary and fecal excretions of calcium and phosphorus frequently are increased in hyperthyroidism. These studies suggested a catabolic action of thyroxine on bone with mobilization of the bone salts. In an effort

to explain the hypercalciuria, Robertson²⁰ theorized a direct action of thyroxine on the kidney with reduction in the renal threshold for calcium, while Hansman and Fraser²¹ expressed the opinion that coexisting hyperparathyroidism is the direct cause of excessive mobilization and excretion of calcium and phosphorus. After recent studies on rats, Engfeldt and Hjertquist²² concluded that thyroxine affects primarily the metabolism of phosphorus by producing an increased concentration of phosphorus in the blood which stimulates the parathyroids to a compensatory increase in function.

All concepts proposed by Robertson,²⁰ Hansman and Fraser,²¹ and Engfeldt and Hjertquist²² involved either primary or secondary hyperfunction of the parathyroid glands, in explanation of the observed alterations in calcium metabolism. These theories may be challenged and considerable clinical and laboratory evidence marshalled to support the contention that no disturbance in the function of the parathyroid glands is present. Aub and co-workers²³ have shown that thyroxine will increase the concentration of calcium in the serum and urine of patients with idiopathic and surgical hypoparathyroidism. Cope and Donaldson²⁴ have reported a case of hypoparathyroidism that developed after subtotal thyroidectomy, in which symptoms of tetany were relieved and the con-

centration of calcium increased in the serum with recurrence of hyperthyroidism.

In cases of primary hyperparathyroidism uncomplicated by renal insufficiency, hypercalcemia and hypophosphatemia are the usual salient findings; but in hyperthyroidism, concentrations of serum calcium and phosphorus are usually normal although, as demonstrated, hypercalcemia may occur. In hyperthyroidism the concentration of calcium in the feces may be high in contrast to the usual normal or low concentrations in hyperparathyroidism. Further contradictory evidence is reported by Askanazy and Rutishauser,²⁵ who found normal parathyroid glands in seven patients having hyperthyroidism with bone disease.

As noted, excessive destruction of bone may be a prominent clinical finding in hyperthyroidism. The bones usually involved are the ribs, pelvis and spinal column. Spontaneous compression fractures of the vertebra have been reported.²⁶ Follis²⁷ found varying degrees of "osteitis fibrosa" in each of twenty patients studied. The disease was manifested by excessive destruction of bone with osteoclastic resorption, by increased vascularity and by proliferation of connective tissue. Osteoporosis, as evidenced by a decrease in the number and size of trabeculae, was present in four cases, with minimal spotty changes compatible with osteomalacia noted in six cases.

In a recent study designed to define altered calcium metabolism associated with thyroid disease with the use of calcium and isotopic dilution techniques, Krane and associates²⁸ found that formation as well as destruction of bone was proceeding at increased rates in the four patients with hyperthyroidism whom they studied. Elevation of the concentration of alkaline phosphatase in some patients with hyperthyroidism without evidence of hepatic disease lends support to these findings. Of interest are findings by the same workers of a similar increase in skeletal turnover of calcium in two patients with Paget's disease of bone. These findings suggested that the turnover of calcium in bones might be related to blood flow, with an increase in the circulation of the skeleton being common to both hyperthyroidism and Paget's disease.

Since little is known about the mechanism responsible for abnormalities of metabolism of calcium in patients with hyperthyroidism without hypercalcemia, it is not surprising that the cause of hypercalcemia in patients with hyperthyroid-

ism remains unsolved. Excessive destruction of the collagenous ground substance of bone with release of large quantities of calcium salts would appear to be a possible explanation. Under these circumstances, the renal capacity for excretion of calcium probably is exceeded. The frequency of occurrence of hypercalcemia in cases of untreated hyperthyroidism has never been accurately determined. In 1945, Puppel and co-workers²⁹ stated that in hyperthyroidism the blood calcium is rarely slightly increased above, and almost never decreased below, the range of normal; yet, as noted, significant hypercalcemia may occur. Despite excessive hypercalciuria which may occur, it is noteworthy that the literature lacks reference to the occurrence of renal calculi in patients with hyperthyroidism.

Summary

Hypercalcemia is one of the manifestations of disturbed calcium metabolism in some patients with hyperthyroidism. The manner in which hyperthyroidism results in hypercalcemia has not been clearly defined. Four cases of hyperthyroidism associated with hypercalcemia and one case of coexisting hyperthyroidism and hyperparathyroidism are presented.

PROBLEMS IN THE EVALUATION OF MITRAL VALVOTOMY

(Continued from Page 748)

be the prior occurrence of systemic emboli. The use of prophylactic penicillin preoperatively and postoperatively may reduce the incidence of acute rheumatic fever postoperatively, and thereby the incidence of recurrent mitral stenosis. Better selection of patients for surgery may result in an improvement in the operative results. Further careful study of patients operated early in our experience with this disease will be necessary in order that the long term value of this operation may be determined.

Treatment of Acute Renal Insufficiency

THOMAS K. OLWIN, M.D.
EDMUND B. FLINK, M.D.

Minneapolis, Minnesota

THE clinical importance of acute renal failure has been more apparent since World War II. The dramatic occurrence of the crush syndrome in England and elsewhere focused attention on the clinical and pathologic aspects of this group of related conditions. There are some excellent monographs on the subject.¹⁻³

Several important therapeutic measures, namely, improved conservative management and the artificial kidney have greatly changed the outlook of anuric patients. Anuria occurs often enough in a general civilian hospital practice to make a discussion of general principles and specific details worth while.

Acute renal failure has been defined by Swan and Merrill¹ as the "clinical syndrome resulting when renal excretory function is rapidly, but temporarily, lost because of alterations in renal circulation and the development of disseminated areas of renal tubular degeneration."

The more common causes are as follows: hemolytic transfusion accidents, crush injury and other severe trauma, prolonged shock, burns, prolonged dehydration, acute liver failure, peritonitis, and poisoning by chemicals such as mercuric, uranium and chromium salts, tartrate, ethylene glycol, carbon tetrachloride, oxalic acid and sulfonamides. Acute glomerulonephritis, acute pyelonephritis, acute bilateral ureteral obstruction, bilateral occlusion of the renal arteries and acute bilateral cortical necrosis of the postpartum period produce acute renal failure with severe oliguria and are difficult to distinguish from the acute renal tubular damage.

The pathology of acute renal failure is complex and varies with the etiology.¹⁻³ It will not be discussed in detail. The reversible nature of the pathology and the great potential of the damaged tubules to heal are worthy of emphasis and are the crux of management. Healing will occur if the

patient can be kept alive for a sufficiently long time.

The pathogenesis of acute renal failure is not clearly established. Some of the probable mechanisms of anuria follow: (1) obstruction of renal tubules with coagulated protein; (2) non-selective reabsorption of all the glomerular filtrate by damaged tubules; (3) leakage of glomerular filtrate through damaged tubules, (4) interstitial edema causing increased pressure, and finally (5) renal ischemia. There probably are elements of more than one of these mechanisms active in many instances.³

There is a protracted and very pronounced disturbance of glomerular and tubular function.^{1,3} The urine to plasma ratio (u/p) for urea is quite low ranging from 1.3 to 2.6.³ Urine specific gravity is in the range of 1.008 to 1.010. Proteinuria is mild to moderate. The urine is usually acid in reaction.

The renal blood flow and oxygen consumption of four subjects with acute renal failure using radioactive Krypton 85⁴ were studied. These measurements were reduced to 20 to 25 per cent of normal.

The general clinical manifestations common to most of these patients will be reviewed. The recognition of anuria or oliguria is not difficult; nevertheless, anuria is often overlooked. Oliguria rather than complete anuria is usual. A urine flow of 25 to 400 ml. of urine is the usual range. An occasional patient with acute renal failure may excrete from 500 to 1000 ml. per day; a progressive uremia and serious hyperpotassemia (especially postoperatively) can occur under these circumstances. Complete anuria should cause one to suspect acute glomerulonephritis, bilateral ureteral obstruction, or bilateral complete renal infarction.

The blood pressure is moderately elevated in most patients. Anemia is often present after a few days of oliguria and uremia.¹ The anemia is well tolerated and doesn't require treatment. Blood transfusions are indicated if massive bleeding has occurred.

From the Medical Service, Veterans Administration Hospital and the Department of Medicine, University of Minnesota.

TABLE I. CAUSES OF ACUTE RENAL INSUFFICIENCY

	Total	Died

**In vitro* dialysis by artificial kidney.

**All these patients had serious primary diseases.

either surgical or nonsurgical. Of this group only three patients survived. Two of the deaths occurred in patients with generalized peritonitis, and could be ascribed primarily to that cause, although one had a potassium of 7.7 and the other 8.4 mEq/l. One patient died of acute pulmonary edema due to excessive fluid administration. One patient with anuria due to a hemolytic transfusion reaction during surgery expired with a rapidly rising BUN, a potassium of 7.9 mEq/l, and a severe tracheobronchitis. The immediate cause of one death was hyperkalemia, and the other three deaths in this group were due to the effects of the

Fig. 1. A plot of the course of blood urea nitrogen determinations illustrates the general course of illness of the entire group.

The mortality rate depends on the type of patient presented. Thirty-nine of the eighty-five patients treated by Swan and Merrill¹ died. Seventeen of thirty-two patients treated by Brun³ died, but only six died of uremia. Twenty-seven of fifty-three patients died as a result of battle injuries and acute renal failure in the Korean War.⁵ Schreiner and Berman⁶ reported that five of sixteen patients with acute portpartum renal insufficiency died.

A series of patients with acute renal insufficiency from 1951 to 1956 were studied at the Minneapolis Veterans Hospital. Fifteen of twenty-seven patients survived. The etiology of the acute renal insufficiency is recorded in Table I.

It can be seen that of the twenty-seven cases, ten were associated with some type of trauma,

uremia. Five of the seventeen nontraumatic cases expired. Of these, one died of acute pulmonary edema and the other four of progressive uremia.

These observations serve to emphasize the often disastrous consequences of renal shutdown in the face of trauma or surgery.

The features of the course of these patients are summarized in Table II.

Figure 1 represents the course of blood urea nitrogen (B.U.N.) in all instances. The individual cases vary considerably, but a general trend is apparent which is useful in understanding the course of the renal impairment. During the first week the B.U.N. rose sharply at a rate which was similar in most cases, with the exception of a few of the milder ones. During the second week there was a general leveling off within the group that

survived. All but three of the deaths occurred prior to the fourteenth day. Of the three, only one survived the first two weeks without the benefit of *in vitro* dialysis. This patient was improving and the B.U.N. was falling, but he died of massive hemorrhage from the colon on the twenty-seventh day. Beyond the fourteenth day a general decline in B.U.N. was noted as renal function was restored. The one case with a rising B.U.N. until the twentieth day was due to ethylene glycol ingestion, and finally cleared completely.

TABLE II. ACUTE RENAL INSUFFICIENCY

	Patients Recovered (15)	Patients Died (12)
Duration of oliguria	1-23	5-27*
Duration of uremia	15-44	5-27
Day of peak diuresis	11-40	
Largest volume of urine	1850-8600	10-1700
Wt. loss after onset of diuresis (kg.)	1.8-9.9	
Intake in excess of measured output per day	693**	1007
Highest BUN	90-243	85-389
Highest potassium	5.0-7.8	5.3-8.9
Lowest sodium	117-136	110-134
Lowest CO ₂	10-25	9-29

*Three *in vitro* dialyses by artificial kidney in this instance.

**Excluding crush injury but swelling of extremity before amputation demanded increased volume of fluid in this patient.

Fig. 2. The course of blood urea nitrogen after onset of diuresis in those who survived illustrates the actual increase or at least plateau of the B.U.N. for some time after onset of diuresis.

The courses of the B.U.N. after onset of diuresis are plotted in Figure 2. The B.U.N. usually continues to rise after diuresis or remains at a plateau for a few days to a week. This fact is important to allay needless worry about the ultimate outcome once diuresis has occurred.

The rapid development of hyperpotassemia in patients with infection or trauma is illustrated in Figure 3. One patient had a sudden occlusion of a femoral artery requiring amputation, and the other had peritonitis. The rapid development of hyperpotassemia after infection and trauma was very well documented by the "kidney team" in the Korean War.⁵

The course of individual patients will be illustrated in the following figures to demonstrate certain clinical and therapeutic problems.

Patient N. S. (Fig. 3), illustrates the need for determining that the ureters are patent. After two

Fig. 3. This figure illustrates the rapid rise of potassium to serious levels in two patients with anuria secondary to gangrene or infection. The potassium is reported in mEq/l.

days of complete anuria cystoscopy was performed. Bilateral ureteral obstruction was encountered. Only the right ureter could be catheterized at this time. Diuresis began immediately. Later the left ureter was also catheterized. The persistence of azotemia for a number of days in spite of diuresis is clearly illustrated.

Patient R. C. (Fig. 5), illustrates the effects of overhydration on serum electrolytes and the subsequent spontaneous recovery. The extent of overhydration is evident from the rapid weight loss following diuresis.

The most important principle of therapy is the limitation of fluids to that amount lost from the body. The amount allowed should not exceed 8 ml/kg. with a top limit of 600 ml. per day in excess of the measurable fluid loss. If fluids are limited adequately, weight loss occurs at the rate of .25 to .5 kg. per day. Even with these pre-

cautions there usually is an accelerated weight loss as soon as diuresis occurs. Bull, Jockes and Lowe⁷ state that they have not seen a patient die before the fourteenth day unless excessive fluids have

Fig. 4. The importance of determining the patency of the collecting system is well illustrated by this patient's course.

been administered. *The need for a careful daily balance sheet cannot be over-emphasized.*

Unless there is excessive vomiting or diarrhea, it is not necessary or desirable to replace the electrolytes lost in this way. If the volume of loss should exceed 500 ml. in one day or more than 1000 ml. cumulative loss, replacement should be made. It is best to analyze the fluid for electrolyte content and to replace the sodium and chloride but not the potassium lost. Sodium lactate or bicarbonate should be used only for extreme acidosis. It is noteworthy that the range of carbon dioxide was the same for those patients who recovered as those who died.

In order to decrease endogenous protein catabolism and consequent accumulation of potassium and other toxic products, it is important to try to administer as many calories as possible. The rate of rise of urea nitrogen can be decreased to one-half of the pretreatment rise by use of 1400

to 2000 calorie protein-free diet.^{8,9} In order to accomplish this, the feedings should begin at very onset of oliguria. Of course, postoperative patients are handicapped in this regard, but it is possible

Fig. 5. The results of over-hydration are illustrated in the excessive weight and the hypochloremia. Spontaneous recovery occurred without specific electrolyte therapy.

in those who do not tolerate oral feedings to administer 15 to 20 per cent glucose solution by polyethylene tube intravenously in volumes described above.

The prompt relief of shock and the adequate correction of acute dehydration are essential in the prevention of renal injury.

The use of potassium adsorbing resin has a definite place in the prevention of hyperpotassemia. The use of chlorpromazine to prevent vomiting of the resin mixture as reported by Wilson et al¹⁰ was the key to their success and can be expanded to improve the retention of the high caloric feedings mentioned above.

Phenobarbital should not be used as a sedative or anticonvulsant, since it can accumulate to a dangerous extent. Amobarbital or other short acting sedatives which are not dependent on renal excretion can be used. Streptomycin must be avoided, since it can accumulate to a toxic level and cause damage to the eighth nerve. Surgical

debridement of devitalized tissue or drainage of an abscess are clearly indicated.⁵

Intermittent peritoneal lavage¹¹ has many of the advantages and few of the disadvantages of continuous lavage which proved to be too hazardous for general use. From 3 to 5 liters of fluid containing sodium, bicarbonate (or lactate) and chloride in the concentrations of normal extracellular fluid, plus 5 per cent glucose and penicillin, can be introduced into the peritoneal cavity and removed five hours later. In this time there has been complete equilibration with the extracellular fluids. It is possible to remove as much as 40 mEq of potassium (depending on the serum level, of course). The chief hazard is that the fluid cannot always be removed.

Dialysis with the artificial kidney is reserved for the most seriously ill patients. The utility of the artificial kidney in tiding a patient over the critical period is well established.^{1,3,5,8} The actual mortality rates do not compare favorably with conservative management because of the selection of only most severely ill patients for dialysis. The most convincing example is that of Swan and Merrill.¹ Thirteen of sixteen patients with serum potassiums from 8.1 to 11.5 mEq/l survived.

Conclusions

The recognition and early treatment of acute renal insufficiency results in the recovery of a majority of patients. Success follows the application of the principles of fluid balance and metabolism. The most important principle is restriction of fluids as outlined above. The prog-

nosis of patients with acute renal insufficiency due to trauma, surgery or severe infection is much less favorable than that of patients who have acute renal insufficiency of other etiology.

A Practical Approach to the Suppression of Lactation

OWEN F. ROBBINS, M.D.
JOHN T. MOEHN, M.D.
MANCIEL T. MITCHELL, M.D.
Minneapolis, Minnesota

IN SPITE of the present-day tendency to return to nature or simplicity of purpose whenever possible, many women either have no desire or find it inconvenient to nurse their babies. This rejection of natural resources without the consent of the body poses a troublesome problem. Many regimens, schedules and medications have evolved in the search for a simple solution.

Today there are three principal methods in use—binders, dehydration, and sex hormones. The practical use of these methods, however, differs with physicians, and there are many different regimens. Each method has its advocates and its critics. Hormone therapy is probably most commonly used.

Object

The series reported upon in this paper was not initiated to determine a definitive approach to suppression of lactation. It is realized that in other hands other methods and regimens may be equally effective. But it is believed that from the standpoint of efficacy, simplicity and practicality, our experience with combined steroids in 1,200 cases deserves reporting.

The paper does not intend to discount the other therapies used to “dry up” the breasts. We no longer give them preference because, in our experience, the complications attending their use sometimes are more tiresome than the benefits received. With combined steroids, however, the excellent results have far outweighed the side effects, which have been negligible.

The method evolved provides comfort to the patient during both the hospital stay and after the patient has returned home. It does not neglect the importance of continued suppression of lactation after discharge. The prevention of recurrent breast engorgement is necessary to insure against discomfort and inconvenience of the patient as well as the attending physician.

Lactation

The physiology of lactation has yet to be satisfactorily and completely explained. Under the

influence of estrogen and progesterone during pregnancy, there is ductular and alveolar proliferation. Thus, the breasts are prepared for secreting milk during the first trimester. However, high estrogen titers inhibit the pituitary's secretion of the lactogenic hormone (prolactin) necessary to actively initiate milk formation. With delivery, this inhibition is removed and the breasts begin to fill.

The mother is usually ready to start nursing late the second postpartum day. However, in the rare patient there is no milk formation. This oversight is difficult to explain, for some patients with apparently no breast tissue have an abundant supply of milk; whereas, a patient with large breasts may not be able to satisfy her baby.

Once nursing is initiated, milk production is continued through a reflex action. Suckling apparently stimulates the secretion of the lactogenic hormone.

Should the patient elect not to nurse her baby, there frequently occurs a painful adjustment during the immediate postpartum period. The release of the lactogenic hormone initiates milk secretion. About seventy-two hours after delivery, the breasts become engorged. Furthermore, headache and general malaise may develop and the breasts become tender and painful. The discomfort frequently necessitates sedatives and strong analgesics for relief.

Rationale

The use of combined steroids is based on the hypothesis that the hormones inhibit the secretion of the lactogenic hormone. It is, in a manner of speaking, a natural approach to the problem.

It has been satisfactorily demonstrated that either estrogen or androgen is capable of suppressing lactation. However, when given alone, side effects may produce conditions more disturbing than painful breasts. Estrogens alone may produce endometrial proliferation resulting in increased lochia and withdrawal bleeding. Androgens may cause virilization.

Combined steroids practically avert these complications; since the two hormones have an additive suppressing effect on the secretion of the lactogenic hormone, it is possible to give smaller doses of each. Furthermore, combined steroids counter-balance the individual influence of each on sex-linked tissue. Finally, combined steroids have a potent anabolic influence desirable after the trauma of delivery. Although the estrogens contribute toward improved electrolyte balance, primarily the beneficial protein anabolic effect is due to the nitrogen retaining power of androgen.

Natural estrogens were chosen because they appear to be tolerated better than synthetic estrogens and because, with them, the incidence of withdrawal bleeding is less frequent.

The medication employed was "Premarin" with Methyltestosterone*, each tablet containing 1.25 mg. of water soluble conjugated estrogens equine and 10 mg. of methyltestosterone.

Regimen

The regimen outlined here is not intended as a hard and fast routine, but as a starting point. Modification may be necessary because of nausea, vomiting, delayed recovery from anesthesia, time of delivery and other practical considerations. In all cases it is important to remember the individuality of each patient and keep the regimen flexible.

As soon as practical after delivery, the patient is given one tablet (1.25 mg. "Premarin"; 10 mg. Methyltestosterone). This dose is repeated three times a day for four days. On the fifth day the dose is reduced to one tablet a day and continued at this level for ten days. Thus, for the average hospital stay of five days, the patient is given 1 tablet three times a day, for the first four days. On the day of discharge and for the first nine days at home, she is given one tablet.

For a patient who starts to nurse her baby but either has no milk or changes her mind, the same regimen is started. She is instructed to start skipping breast feedings and substitute a bottle in the following manner. Skip one feeding the first day; two, the second, et cetera, until the baby is being fed entirely by bottle. "Premarin" with Methyltestosterone is given from the first day as previously described. It should not be forgotten that once lactation has been initiated suppression is more difficult.

By this regimen the reflex secretion of the lactogenic hormone is gradually eliminated while the estrogen and androgen suppress the pituitary secretion of this hormone.

Adjunctive Measures

Should a patient complain of engorgement on the third postpartum day, she is given stilbestrol (5 mg.) stat. (To soften hard breasts, a nursing patient is also given 5 mg. of stilbestrol).

Analgesics are not needed except in the rare case, the failures. Some patients, however, do receive analgesics on the first few postpartum days for other reasons, such as the pain and discomfort of an episiotomy.

All patients wear loose binders, no different from those worn by nursing mothers. Because these binders do not exert any pressure whatsoever on the breast, they cannot be considered to play a role in suppressing lactation. They served no more than as a loose support.

Although restriction of fluids is not a part of the regimen *per se*, the patients do not receive copious amounts. They are told to drink liquids sparingly. No patient receives a diuretic.

Selection of Patients

During a three-year period we delivered in private practice 2,853 patients. It was necessary to suppress lactation in 1,302. Of these, 1,194 were given "Premarin" with Methyltestosterone and are reported in this series. The remaining ninety-three are not included because they either received nothing or were given other medications.

The number who did not receive combined steroids was insufficient to use as a control. Furthermore, in view of the good results it was not deemed advisable in private practice to deny patients the benefit of this therapy for the sake of a control series, especially when the excellent results are substantiated in a series of almost 1,200 cases.

Results

The results were graded in relation to the achievement of the aim of therapy—successful suppression of lactation with the least discomfort and inconvenience. The following three categories were used:

Excellent: Lactation successfully suppressed with no discomfort to the patient during the first fourteen postpartum days with no side effects.

*Ayerst Laboratories, 22 East 40th Street, New York City.

TABLE 1. RESULTS ACHIEVED WITH
"PREMARIN" THERAPY

Day Therapy Started	Excellent No. %	Satisfactory No. %	Failures No. %	Total
1st day	690 75.2	196 21.3	32 3.5	918
2nd day	130 74.3	38 21.7	7 4.0	175
3rd day	32 68.1	12 25.5	3 6.4	47
4th day	26 60.5	13 30.2	4 9.3	43
Over 4 days	7 63.6	3 27.3	1 9.1	11
Total	885 74.1	262 22.0	47 3.9	1194

A slight leakage of milk from the breast was not considered undesirable.

Satisfactory: This category includes the patients whose lactation was successfully suppressed but who, on the third or fourth postpartum day, noted slight engorgement and were given 5 mg. of stilbestrol. There were no complications.

Failure: Tender, painful or engorged breasts classified the patient as "failure." If the patient made any complaint at all that her breasts were painful, she was classified as unsatisfactory.

The therapy has been most gratifying. In only 3.9 per cent of the patients was it a failure. Eight hundred and eighty-five (74.1 per cent) were never aware of any physiologic adjustment taking place in their breasts. Two hundred and sixty-two (22.0 per cent) noted a full sensation about the third postpartum day. The sensation was not uncomfortable or painful but did signify activity of the glandular tissue. In final appraisal, the regimen permitted 1,147 or 96.1 per cent of the patients to circumvent the discomfort and inconvenience frequently associated with "drying up" the breasts.

Side Effects

Side effects were absent. There were no cases of postpartum bleeding which could be attributed to the "Premarin" with Methyltestosterone. There were no delayed menses, no excessive lochia or signs of virilization. There was no nausea or vomiting due to the combined steroids.

Observations

Although the comprehensive benefits without side effects are attributable to the administration

of both estrogen and androgen, estrogen alone can play an important role in the suppression of lactation. This is demonstrated by the fact that stilbestrol given in one dose softens the breasts. However, because side effects are more frequent with the female hormone alone, combined steroids are used routinely.

Although we did not evaluate it in more than a few cases, a short course with larger doses of combined steroids showed relatively good results. However, a more protracted regimen of one tablet daily for ten days after the initial course acts as insurance against "rebound" filling of the breasts.

The time of initiation of therapy should be considered. Although we do not feel that it is necessary to initiate therapy immediately after delivery, we have observed that unnecessary delay reduces the possibility of excellent results. Referring to the chart, there is noted a general tendency to fewer "excellent" and more "satisfactory" results and "failures" with increased time after delivery. This tendency is not marked, and as the study was not set up to compare the different times of administration no conclusions can be drawn.

One important practical advantage of this regimen is that it can be administered without fear of undesirable side effects. This is due primarily to the relatively small amounts of the individual hormones administered, plus their balancing action on sex-linked tissue.

Summary and Conclusions

In a series of 1,194 patients combined steroids was used to suppress lactation. The regimen was three tablets three times a day the first four postpartum days and one tablet daily for ten days thereafter. Evaluated in relation to the achievement of the aim of therapy—comfort for both the patient and attending staff—the regimen was successful in 96.1 per cent of the cases. There were no side effects or complications attending the therapy. In our hands, the use of combined steroids ("Premarin" with Methyltestosterone) has practically solved the problem of suppressing lactation.

Counseling with the Hearing-handicapped Child and his Parents

LEROY D. HEDGEcock, Ph.D.
Rochester, Minnesota

THE FIRST problem to be faced in counseling children with impaired hearing is that of identifying them as early as possible. Deafness is not so easily detected as blindness or crippling. This is particularly true when the loss of hearing is incomplete, but even total deafness may go unrecognized for a number of years in early childhood.

Although there is no certain means of identifying deaf babies, a number of clues are likely to suggest deafness at an early age. If a baby responds to visual and tactile stimuli but not to sound, the possibility of deficient hearing must be considered. The probability of deafness is high if an otherwise alert child is not awakened or occasionally startled by loud sounds. By the time a normal child is a year old he may be expected to notice the speech of others even if he does not produce words himself. Failure to develop speech at the appropriate age or an unusual quality of voice may indicate failure to hear perfectly.

At a later stage the child who does not come when he is called, and does not follow directions well, may not be disobedient, as probably will be thought; he may be hard of hearing. The child who is restless and inattentive in school or who sits quietly by himself and does not participate in the activities of the classroom may behave this way because he does not hear well. Every child who must repeat a grade in school should be studied carefully to determine whether defective hearing is the cause of his failure. It is hoped that either schools or public health agencies will conduct audiometric tests regularly so that all

children will be checked for acuity of hearing frequently during their elementary school years.

After a child is known or suspected to be deficient in hearing, the important problem is to determine the amount and type of deafness. There are a number of ways to measure the hearing of children. By the use of one or more of the appropriate techniques it is usually possible to make a reasonably accurate evaluation of the degree and type of deafness.

Most children four years old or older can be tested either by routine audiometry or by play audiometry. Frequently three-year-olds and occasionally even younger children will respond to games in which controlled sound is used as a stimulus for overt responses. Speech audiometry may be employed in a number of ways to add information about a child's hearing. Among young children the commonest type of response to speech signals is that of following directions, as by pointing to objects or pictures. Older children may respond as adults usually do, by answering questions or repeating words.

Possibly the most objective means of observing a child's response to sound is the measurement of electrical changes that occur in the skin when sound and associated stimuli are employed. This technique, which is known as "psychogalvanic skin-resistance" audiometry, has been hailed as the best answer to the problems involved in measuring the hearing of very young children. Although it has proved helpful to some examiners, other observers consider that it has left much to be desired. Certainly it has not replaced the need for keen observation and judgment in interpreting the outward behavior of children. Some trained examiners can judge the acuity of hearing with remarkable accuracy by observing reflex and gross reactions to various sounds in a child's environment.

From the Section of Otolaryngology and Rhinology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Presented at the Center for Continuation Study, University of Minnesota, October 1-3, 1957.

The results of audiometric tests along with thorough otologic examination and medical history of a child with hearing difficulty should reveal the type of deafness that is present. Fortunately, the vast majority of losses of hearing found in children are of the conductive type of deafness due to obstructions in the transmission of sound. Most of these losses may be expected to respond favorably to medical or surgical care if appropriate treatment is applied before permanent damage occurs.

A small but significant percentage of deafness among children is perceptive in nature. In perceptive or nerve deafness the failure is in the structures of the inner ear or in the auditory nerve proper. Most losses of hearing of this type are not amenable to either medical or surgical treatment.

After a diagnosis of perceptive deafness has been established, it is important that attention be given to compensatory and educational measures designed to alleviate the handicap. One of the first considerations for a child who has permanent loss of hearing is the use of a hearing aid. If the loss is enough to cause difficulty in understanding speech and is not too severe to permit benefit from amplification, a hearing aid probably should be provided. Many children are now wearing hearing aids satisfactorily. Most current instruments are small and convenient to wear, and at the same time provide relatively good amplification of speech. If the degree and type of deafness can be determined with reasonable accuracy, it usually is not difficult to select a suitable hearing aid. Certain basic considerations with regard to the type of instrument and the way it should be worn need the attention of an otologist and an audiologist.

The problems and limitations of hearing aids should be understood by parents and teachers of children who wear them. To some extent these problems are similar for all users of hearing aids, but more important than the similarities are the individual reactions to amplified sound. A hearing aid does not improve the ability to hear; rather it may improve the signal to be heard. This basic fact often is ignored in the desire to solve all problems of hearing by supplying an instrument. It is not unusual to encounter degrees and types of deafness for which a hearing aid is of no significant benefit.

One of the most important and useful skills

for any person with defective hearing is that of reading speech from visual clues. The ability to read speech can be developed into an accomplishment of remarkable proportions. A skillful speech reader learns to take into account the whole situation, including the gross environment as well as the minute details of facial and body movement. This skill is helpful in communication regardless of the degree or type of deafness. Of course, the specific goals and the extent to which speech reading is used will vary with the degree of deafness and with the maturity of the pupil. It is desirable that all children with permanent disability in hearing start learning to read speech as early as possible. As soon as a child can be induced to watch the face of someone talking to him, he is ready to start making associations between the movements and expressions he sees and the articles or situations at hand. Fortunately much of this skill may develop naturally along with the general powers of observation. However, in addition to this natural development, it is beneficial to provide systematic instruction and a high level of motivation. As in all learning, the goals should be placed so that success becomes a motivating force.

In addition to the use of a hearing aid and the practice of speech reading, most children with partial loss of hearing can benefit from training and practice in effective listening. Poor hearing is likely to be accompanied by poor habits of listening. Auditory training for children is designed to develop and utilize the residual hearing as effectively as possible. Whether a hearing aid is used or not, this aspect of training can be employed, and it should be started as soon as the loss of hearing is discovered.

Since the production of speech is normally motivated and controlled by auditory stimulation, any defect in hearing may result in defective speech. This effect may be minimized by training in the use of visual, tactile and kinesthetic senses to help regulate the production of speech. Most children with some degree of hearing can learn to speak satisfactorily. Even the totally deaf may learn to speak intelligibly, although the rhythm and quality of voice are never normal. Again, it is important that proper stimulation and training be instituted as early as possible.

It is apparent that much of the emphasis in

(Continued on Page 800)

Pathologic Fractures Due to Metastatic Bone Disease

LEONARD F. PELTIER, M.D., Ph.D.

Kansas City, Kansas

THE DEGREE of damage to the structural integrity of the bone by a metastatic cancer depends upon many factors. The osteolytic properties of individual tumors vary considerably, and the behavior of any one tumor can change during the course, either spontaneously or as it is affected by systemic or local treatment. In addition to the effect of the local tumor deposit itself, the adjacent bone may be further weakened by atrophy accompanying disuse and debility, and by the effects of irradiation directed at the metastatic lesion. When the involved bone can no longer support the stress of the patient's activity, pathologic fracture occurs.

Occasionally, such a fracture may be the first sign of metastatic bone disease. In most cases, however, a diagnosis of cancer has already been made and the patient is under treatment or observation. Bone pain is usually present and well localized prior to fracture. It is well, therefore, to emphasize the value of *prophylaxis* in the management of pathologic fractures. Trouble can be anticipated. The discovery of a small osteolytic lesion followed by the institution of treatment by irradiation will frequently lead to the arrest of bone destruction. Systemic treatment with hormones or other chemical agents may accomplish the same result. Predilection to fracture is decreased.

Corsets or braces may be used to protect weakened areas in the vertebral bodies. Crutches can be used to decrease the stress of bearing weight during ambulation. If a real threat of pathologic fracture exists, the patient's activities can be further restricted. If such a lesion is present in a long bone and can be suitably supported with

an intramedullary nail, prophylactic nailing, before fracture occurs, is indicated.

When pathologic fracture occurs, it is commonly associated with only incidental trauma. Indeed, such fractures have been referred to for years as spontaneous fractures. A cough, a turning in bed, a sudden muscular effort, may fracture even the shaft of the femur. The history of the injury producing the fracture is an important diagnostic feature; by its very insignificance it should draw attention to the possibility that the fracture is a pathologic one.

Since the trauma producing fracture is small, the displacement of the fracture fragments is usually slight. Gross deformities are unusual. This is confirmed by the radiographs. The collapse of the weakened area of bone results in a transverse fracture line whose edges may be ragged and poorly defined. The fragments do not look as though they would fit neatly together when reduced. There may be other areas of metastatic bone disease visible above or below the fracture or in adjacent bones. In most cases bone atrophy is also present. The diagnosis of pathologic fracture can be suspected or established by the examination of the initial radiographs in almost every case.

The principles governing the management of pathologic fractures are no different than those in other fractures. Their object is to relieve pain and to restore function as quickly as possible. Time is of the essence in the patient with metastatic bone disease, for his life expectancy is usually short. For this reason those methods permitting early activity of the patient, even in a limited way, are to be preferred to those requiring prolonged immobilization. Open reduction and internal fixation with intramedullary nails or pins is the ideal method for the treatment of pathologic fractures of the shaft of the femur or humerus. A combination nail-plate can often be used for patho-

Formerly Associate Professor and Acting Head Division of Orthopedic Surgery, University of Minnesota, Minneapolis, Minnesota. Dr. Peltier is now Professor of Surgery and Head, Section of Orthopedic Surgery, University of Kansas Medical Center.

Presented at the Center for Continuation Study, University of Minnesota, November 21, 1956.

logic fractures in the trochanteric region of the femur. The chief prerequisite for successful internal fixation is the presence of bone, on either side of the fracture, sufficiently strong to allow adequate purchase for fixation. If any irradiation is to be given to the site of fracture to control the local tumor growth, it should be given prior to internal fixation, since the presence of large metallic foreign bodies in the field to be irradiated greatly affects the dose actually delivered to the tissue.

Unfortunately, many pathologic fractures are not suitable for internal fixation and more conservative means must be used. Every effort should be directed toward allowing as much activity as possible. The criterion of adequate immobilization is the relief of pain, and this often can be achieved by a dressing which would be manifestly inadequate to manage a normal fracture. Frequently, although the fracture may initially require strict immobilization, after treatment of the metastatic

lesion, the amount of immobilization required can slowly be reduced to a minimum.

If the pain of the fracture cannot be controlled or if the function of the limb is compromised by continued tumor growth, lymphedema, or thrombosis, amputation should be strongly urged as a palliative measure. When this is not possible, chordotomy should be considered.

A surprising number of pathologic fractures will show evidence of healing, especially when the tumor has been actively treated. Some will go on to solid union with restoration of function.

Pathologic fracture is a complication of metastatic bone disease. Whenever possible, fracture should be prevented by active prophylaxis. When fracture occurs, the underlying malignant disease remains the major problem and should not be obscured by preoccupation with the fracture. In all of these situations, continuing efforts should be made to control the growth of the tumor.

COUNSELING WITH THE HEARING-HANDICAPPED CHILD AND HIS PARENTS

(Continued from Page 798)

meeting the needs of children with defective hearing lies in early recognition and training. This places a serious responsibility on the parents of such children, since many of the rehabilitative measures should start before the usual age of attending school. When parents learn that their child of preschool age has a permanent impairment of hearing, they are faced with the alternatives of directing the early training themselves or finding facilities for this type of training. The latter course usually is more desirable, since most parents do not have eminent success in the formal aspects of teaching their own child. It is imperative, however, that parents learn to co-operate with the school and to supplement the work of the specially-trained teacher. When parents do accept the major responsibility of teaching their child, care must be taken that they do not neglect their role as effective parents. The child who gains an energetic teacher but loses a loving par-

ent is not a fortunate child. The most important thing that parents can do for a handicapped child is to give him the affection and security of normal family life. This means that he must learn to share the responsibilities as well as the pleasures of the home. It means that he should receive generous recognition and praise for worthy accomplishments, and appropriate restraints and discipline when they are needed. It requires conscientious effort by a whole family to keep from spoiling a physically handicapped child. If this effort is not successful, the result is that an emotional handicap is added to the physical one.

There is abundant literature designed to help parents of children with impaired hearing, and many schools and clinics offer guidance to parents as well as instruction to children. If all the information and facilities for meeting the problems of impaired hearing are utilized effectively, the results are exceedingly worth while.

Clinical Notes

Basic Laboratory Procedures

CHARLES VANDERSLUIS, M.D.

Bemidji, Minnesota

The most difficult and time-consuming part of our practice is diagnosis. It seems more burdensome because of the need for laboratory work which is sometimes deferred or influences us in sending the patient to a hospital where all of this is done at increased cost to the patient or to an insurance company and at no profit to ourselves, and, sometimes, to our subsequent embarrassment when or if the patient realizes that he really did not get much good out of his hospital stay. There is the additional chance that the hospital laboratory work, because of the volume and routine nature of it, may not be accurate, even in the hands of experienced technicians, and the work needs repetition. The office should be the diagnostic workshop. This is the best place to iron out "bugs" or inconsistencies.

Medicine can be practiced without laboratory aids, but not so well as with them. Strange as it may seem, within the past year two diabetic patients running urinary sugar have come into the office. These were previously undiagnosed although seen a number of times elsewhere for complaints due to their diabetes mellitus. Their doctors were reluctant to do even elementary laboratory work. Just as no general practitioner can do his patients justice without at least a fluoroscope (because pneumonia in children and adults is no longer susceptible of definite detection by physician examination), neither can he do his patients justice without at least a coarse screen of laboratory work.

Feeling that routine laboratory tests are as yielding of useful information as the average physical examination, I have devised a little battery of them which can be run through rapidly on urine and blood samples and can be taught readily to a previously untrained assistant.

As Figure 1 shows, urinalysis bottles are kept in order on the top of the rack over the sink.

Presented at the meeting of the Upper Mississippi Medical Society, Bemidji, Minnesota, June 15, 1957.

These give, in addition to the usual routine, a Sulkowitch and urobilinogen determination.

The albumin reagent, Bunitest, or a 5 per cent solution of sulfosalicylic acid, is added to urine from a TK dropper bottle. Any quantity of albumin is checked by heat and 5 per cent acetic acid because false positives occur occasionally, notably in patients taking Gantrisin. False negatives have not been seen here. Clinitest is still used for sugar, rather than Clinistix or Testape, because the tube can be shaken and set in a rack for observation as fast as the tape can be balanced on the edge of the sink or put in a clip. A small bowl of water with a medicine dropper in it sits within easy working distance.

The Sulkowitch test is run simply by adding about 1 cc. of the reagent from a TK dropper bottle to about 2 cc. of urine. A moderate amount of white precipitate of calcium oxalate is normal. A lesser precipitate is common in urines of low specific gravity and in children, and in adults it raises the question of a low blood protein, which is accompanied by low blood calcium, as well as other possibilities. Small amounts of precipitate sometimes take a minute to appear, so the tube cannot be dumped without being allowed to sit. A heavy milky precipitate will be rarely seen, but when it occurs it raises the suspicion of high blood calcium and enables one to suspect hyperparathyroidism, which is otherwise easy to miss. In pregnancy, a rather heavy precipitate generally forms rapidly, and this must usually be ascribed to the conditions of gestation. This test should be repeated several times on different days before drawing definite conclusions or ordering a blood calcium, which is difficult to perform or obtain in small towns.

Urine urobilinogen is easily checked by adding to a small amount of urine an equal amount of Watson's modification of the Ehrlich reagent, and, to this mixture, an equal amount of saturated solution of sodium acetate solution, both

poured from TK dropper bottles. This test is negative or only faintly pink in a normal urine but gives varying degrees of red, extending to red-dish purple, in urines containing abnormal

Fig. 1. Urinalysis bottles in position above sink.

amounts of urobilinogen or porphobilinogen. These two latter compounds can be differentiated by adding chloroform, which will take up the red of urobilinogen and be colored, but will remain clear in the presence of porphyrins.[†] All positive Ehrlich tests are repeated after washing out the test tube because oftentimes there is enough contaminant in a tube which has been used for forgotten tests to give a false positive reaction.

Urine urobilinogen has been particularly useful in cases of jaundice. Hepatitis sometimes shows a positive urine urobilinogen early in the disease be-

[†]By the use of this routine Watson-modified Ehrlich test, I recently found a patient who repeatedly ran a 4-plus "urobilinogen." Dr. C. J. Watson, of the University of Minnesota Medical School, set me right by identifying this substance as porphobilinogen and he went on, by spectrographic means, to identify large amounts of uroporphyrin and coproporphyrin and make a diagnosis of acute intermittent porphyria. Unfortunately, some porphyrias can be missed by this routine Watson-modified Ehrlich test if porphobilinogen is absent or small in amount because uroporphyrin and coproporphyrin do not give a positive Ehrlich reaction.

There have been a few inconsistencies in these "urobilinogen" tests, for which I do not know the explanation. After placing an Ehrlich-positive urine in the ice box for a day for conversion to urobilin so that the Schlesinger test (green fluorescence with compound solution of iodine and saturated alcoholic solution of zinc acetate) can be run on it, the Ehrlich test will continue as positive as ever; so it must be considered equally sensitive to urobilin. However, when I formerly ran only the Schlesinger test on urine from patients following coronary occlusion, it seems to me I found a much higher number of positives than since I forsook this test in favor of the simpler Watson-Ehrlich test. I am going back to Schlesinger's test in these cases and run the Ehrlich test on these which are positive to see whether there is a discrepancy, which I suspect is present.

fore jaundice occurs, and at times jaundice fails to appear. In hepatitis with jaundice, the urine urobilinogen is usually strongly positive, paralleling the cephalin flocculation test results, while in

Fig. 2. Small office laboratory.

cases of pure obstructive jaundice the urine urobilinogen is negative or very slightly positive. Urine urobilinogen may be persistently positive in cases of congestive heart failure, but in my experience the variabilities in reaction cannot be linked with the state of compensation. Urine urobilinogen may be temporarily positive in cases of internal hemorrhage or infarct, pneumonia, and untreated pernicious anemia, and often for undetermined reasons, but it is important to recheck immediately positive results on the same specimen, as indicated above.

This Ehrlich test will not show a normal reaction in urines containing sulfa, but will turn the urine yellow. This has the advantage of showing that the patient has been taking sulfa in some form, whereas the urine sediment cannot be relied upon to show crystals. While all this has been going on, the urine is spinning in the centrifuge, and the centrifuge can now be stopped and the sediment examined. Oftentimes the supernatant urine is more clear than the original specimen and gives a better test for albumin and calcium.

Ictotest, manufactured by the Ames Company, is the easiest reagent for use in determining the presence of bile. It is rapid and sensitive and is used on suspected urines. The above urine examination can be done in two or three minutes.

The routine procedure for blood examination requires between ten and fifteen minutes. Four cc. of arm blood are drawn and some is poured from the syringe into a small Cutler sedimenta-

tion tube containing 4 per cent sodium citrate up to the mark, and this tube is quickly and gently shaken. The rest of the blood is poured into a Wassermann-size vial containing the evaporated

poured into the glass cell of a wedge-type hemoglobinometer. Smears from this blood are satisfactory for a differential count, but better smears for cell morphology can be made directly from

Fig. 3. Small office laboratory.

residue of 1/2 cc. of a solution of 2.4 grams of ammonium oxalate and 1.6 grams of potassium oxalate in 200 cc. of distilled water (dried in an incubator).^{*} This vial is immediately and gently shaken to avoid clotting. One cc. of this oxalated blood is immediately drawn back into the same syringe to fill a Wintrobe sedimentation tube, which is gently shaken from end to end and then set in the Wintrobe rack. The timer is set for an hour for both the Cutler and Wintrobe rates.

The rest of the oxalated blood in the vial is used to fill pipettes for the counts, and a little is

^{*}When this article was originally written, I was using 2 drops of 20 per cent potassium oxalate solution in a Wassermann tube as a blood anticoagulant. Because of low hematocrit readings, I returned to the oxalate mixture residue, in spite of the fact that clotting occurred more often, because the hematocrit readings were higher and more consistent with the red count and hemoglobin values. Just why 20 per cent potassium oxalate solution leads to abnormal cell packing, I do not know. Hemolysis was not visible in the tubes. A table is presented with comparative values of sedimentation rates and packed corpuscular volume hematocrit) using different sedimentation tubes and different anticoagulants.

Case	Sedimentation Rate			Hematocrit Per Cent		Icterus Index Units	
	Cutler	Wintrobe Ox. Mixt.	20% K Ox.	Ox. Mixt.	20% K Ox.	Ox. Mixt.	20% K Ox.
1 HD	25	47	44	43	33		
2 SF	7	9 1/2	8 1/2	44	35	10	10
3 EG	9	16	13	45 1/2	37	10	5
4 AP	20	29	28	35	28	10	5
5 LM	15	22	16	37 1/2	29 1/2	15	15
6 PS	11	11	17	47	40	17 1/2	
7 RB	5	6	6	41 1/2	35 1/2	12 1/2	12 1/2

One can see from the above that it is necessary to use similar tubes and similar anticoagulants in order to compare readings of sedimentation rates and packed corpuscular volume.

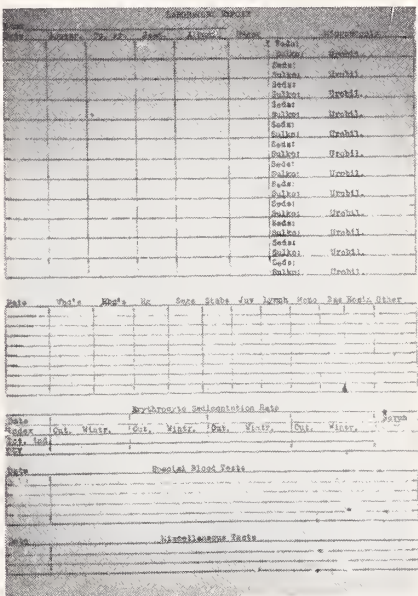

Fig. 4. Mimeographed office laboratory sheet.

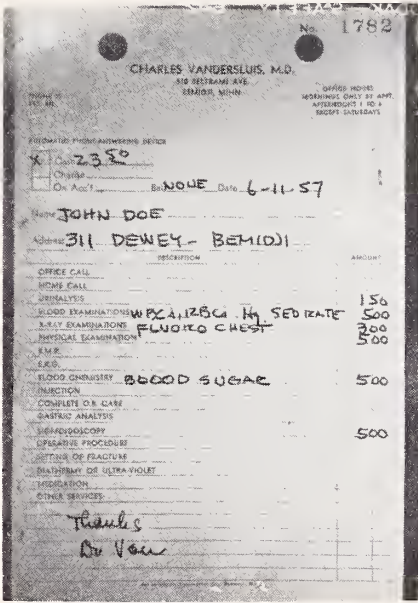

Fig. 5. Sheet from Moore billing machine.

the nonoxalated blood, although taking this from the syringe slows up handling of the blood and may result in clotting of the oxalated blood. Differential blood counts are done only on abnormal blood and are usually taken from the finger tip so that cell morphology can be appreciated. When well done, they are time-consuming.

An American Optical hemoglobinometer cell is filled by discarding a little blood from the vial into the sink in order to wet the edge of the vial and then pouring directly from the vial lip into the cell. It is stirred in the cell with an hemolysis stick and the hemoglobin read in a minute. This method is not subject to the error of the Sahli method in that addition of water or any other reagent is not necessary. The results match those of photoelectric colorimeters.

The advantage of running two sedimentation rates is that one serves as a check on the other. Sedimentation rates are subject to error because of clotting of blood in the tube and other undetermined causes of misbehavior. The Wintrobe reading is about double the Cutler reading when the rate is abnormally high, while the normal values approximate each other within the range of 0 to 8. The Wintrobe method gives one the advantage of an hematocrit reading, in case one is doubtful about the presence of anemia or plethora. The Wintrobe tube can be spun for half an hour in the centrifuge or can be left in the centrifuge and spun during the day with the urines until a few observations show that the red cells do not pack any lower. The supernatant plasma can then be observed for color and, if it looks icteric, it can be compared with icterus index standards in the Wintrobe tube rack. If one is doubtful about the type of anemia one can get a lead by observing the plasma, which is slightly icteric in pernicious anemia and pale in hypochromic anemia. One can get further information by calculating the red cell volume and red cell hemoglobin concentration from the hematocrit reading and red count and hemoglobin values. For the hemoglobin concentration within the red cells, however, one must determine a standard of

normal hemoglobin in his practice and call this 100 per cent because three scales of 100 per cent are in current use—15.6, 14.5 and 13.8 grams per cent. On the American Optical hemoglobinometer, the grams are read directly, and below this figure are the percentages of all the scales named above. In my practice 14.5 grams per cent is the closest to a standard of normal. It is helpful to supply the hospital laboratory with the Cutler and Wintrobe tubes for use with your patients if you adopt this method, so that you can apply hospital findings to the office findings. It is impossible to translate a Westergren sedimentation rate to a Cutler or Wintrobe reading, because of the much greater tube length of the former. It is worthwhile to invest in a Wintrobe icterus index standard rack to determine icterus index. Although carotins and hemolysis can interfere at times, in practice this rarely happens.

The routine cancer detection examination has encouraged more stool examinations for occult blood, and this is confusing, because small traces of blood are found with Hematest, as well as with other reagent combinations. The most one can say is that more definitive examinations, such as proctoscopy, sigmoidoscopy and x-ray examinations have resulted, and these have been valuable in stimulating examination for the notoriously silent gastrointestinal tract malignancies.

Pictures of a good small office laboratory are shown (Figs. 2 and 3), occupying three sides of a small room. A picture of a mimeographed office laboratory sheet, which has stood the test of years, is likewise presented (Fig. 4). The picture of the billing sheet, from a Moore billing machine, is shown for what appeal it might have to those of you who like to let the patient know what work has been done, as well as what the charges are (Fig. 5).

ENDOCRINOPATHIES IN CHILDHOOD

KEEPING OUR PHYSICAL FINDINGS UP TO DATE

New laboratory techniques are becoming available to the clinician almost every day to aid him in diagnosing his patients' ills. With attention focused on these innovations, appreciation of the value of physical signs is likely to suffer. The thoracic roentgenogram is one of the procedures considered by some to have replaced physical examination of the indicated structures. Yet the roentgenologist actually is the first to point out the limitations of the roentgenogram. Like any other laboratory aid, the "chest x-ray" is of value only as it is integrated with total clinical evaluation.

The disrepute of the stethoscope has been marked by statements referring to it as a museum piece. Yet there are many instances in which stethoscopic findings will elicit abnormalities not seen on the standard postero-anterior thoracic roentgenogram. Stethoscopic evaluation of cardiac sounds and murmurs need not be defended. There are numerous other, less commonly appreciated situations in which the physical examination alone may elicit a given abnormality.

Occasionally, as much as 1,500 ml. of pleural fluid may be obscured behind the dome of the diaphragm, and be discovered only by careful percussion and auscultation. Radiolucent foreign bodies in the bronchi may cause only partial luminal obstruction for days or weeks, so that obstructive pneumonitis cannot be seen in the full-inspiration roentgenogram. Yet physical examination in such a condition will reveal an area of decreased breath sounds associated with normal resonance.

Another group of conditions in which the "chest x-ray" may be "negative" includes the spectrum of bronchitis, bronchiectasis and emphysema. Asthma might also be included in this group, the abnormalities usually being cyclic or episodic. Rales, rhonchi and prolongation of the expiratory breath sounds demonstrate obstruction of the airway by bronchospasm, altered bronchial secretions or lack of elastic support from the surrounding pulmonary parenchyma. The presence of decreased breath sounds in underventilated

but distended portions of emphysematous lungs further delineates the abnormalities. Percussion of the level of the depressed diaphragm and demonstration of meager motion, even in the extremes of inspiration and expiration, may tell the clinician of the severity of the disorder. Studies of pulmonary function have depicted graphically the expiratory slowing and impaired distribution of gases found in the presence of these disorders, yet many of these abnormalities may be estimated clinically. These are only a few examples to indicate how physical diagnosis is one key to sound medical practice.

As new laboratory methods become available for measurement of altered function, it is the responsibility of those in clinical fields to correlate the data thus obtained with altered physical signs. Frequently, the correlation is close enough so that the general use of some laboratory procedures is not necessary. Only patients who present difficult diagnostic problems may have to undergo more elaborate studies. If physical findings are to continue to play a major role in the clinical evaluation and care of patients, the physician must continuously adjust his standards of various physical findings to fit new discoveries in the laboratory sciences. This can be done by medical reading and by thoughtful application of new discoveries to the physical examination.

The physician who can make diagnoses only with the aid of a battery of laboratory data degrades himself to the point of doing clerical work, and he loses the art of medicine. Furthermore, he does his patient an injustice professionally and financially. Careful clinical evaluation, supported by the results of a few specifically directed laboratory tests, in most instances will result in a satisfied and properly managed patient. These high standards that our patients set for us call for our constant vigilance and re-evaluation of clinical procedures.

R. DREW MILLER, M.D.

THE MARLBORO(UGH) MAN

Ask any sports fan to give you a description of the Marlboro Man and you get a composite something like this. He's effective, if slightly awkward

with an axe. He has a tattoo on his wrist (the clash of symbols here is variously interpreted: he was once a real heller; he is unable to find a plastic surgeon who is willing to remove the double eagle; in a moment of sheer ecstasy born of smoking a cigarette, the brand of which shall remain anonymous, he leaned against a freshly inked stencil; et cetera). Keen observers suspect that the tattoo shifts from wrist to wrist. He rides a horse, runs a ranch, flies a plane in a swirl of dust. He has a slightly husky voice (one iconoclast has suggested that his titer of androgens has been artificially boosted). And he dexterously manipulates a flip-top box. All-in-all, he is the type of gent whom those wordly wise psychologists, the advertising men, have packed with every gimmick they can dream up to indicate that here is a real he-man who customarily spends his waking hours with a cigarette in each hand and some badge of masculinity in the other.

All this is such common knowledge that a recent paragraph in the News of Science section of *Science** came as a thunderclap out of a clear sky. The paragraph was headed: Marlborough Man. Now this Marlborough Man is different from the Marlboro Man; indeed, no one has proof that the Marlborough Man had lungs, or any other mechanism to permit him to inhale deeply and luxuriously. *Science's* Marlborough Man had "a large head and heavy jaw similar to that of the Boscop Man. (Why doesn't somebody rush off and sell manufacturers on the idea of having a cigarette named Boscop? The singing commercials should be lovely) discovered in South Africa." Further, he is unique because "the skull is that of a man not resembling any existing race living in Africa today. Some features of the bone structure . . . differ from those of both the European and the Bantu." If *Mad Comics* doesn't get there first, we should be able to work this distinctive Marlborough Man into an irresistible selling force.

H.M.

**Science*, 19 April, 1957, p. 731.

THE MATURATION OF THE CARDIOLOGIST

The recent advances in the field of cardiovascular diseases during the past twenty years have resulted in the production of distinct heaves,

thrills, and murmurs in the walls of the house of cardiology. The occupants of said house, needless to say, were quite shaken and depolarized. Some remained depolarized, while the majority quickly underwent repolarization and took stock of the deficiencies of the old building which had stood so long and so well on hallowed ground in an atmosphere of commanding respect. It was quickly appreciated that the foundation, which had been assumed by all to be staunchly constructed and tremor-proof, was constructed, instead of the bricks and mortar of sound scientific research and observation, of a brick veneer of traditional concepts based on grossly (and at times erroneously) related clinico-pathologic findings.

As is the case in all things concerned with our mode of living during these past twenty years, progress has been circumferential. At this point, one might speculate at the concomitant increase in medical research during this same twenty-year span. It is obvious that the basic research done in the early years of this period was instrumental in the erection of a new and much stronger foundation for the house of cardiology. It also became apparent that occupancy of said house was not only much more demanding, but also much more exacting. No longer was the classical portrait of the bedside stethoscopic evaluation of the cardiac disease to be visualized in its time-honored position on the mantel over the fireplace. It, too, became a victim of the new architect and interior decorator. A new era then came into being. The standard three-lead electrocardiogram, with full acknowledgement to Sir Thomas Lewis, Emthoven and Fahr, was placed in a much smaller frame and put in its place on the mantel. It was at this time that the occupants of this house were distinctive among their guests, because they could look at the new portrait above the mantel and interpret it, whereas the guests could not. Thus a "Man of Distinction," to quote a famous slogan, was born, and a label of cardiologist was affixed. The untiring and intrepid efforts of Wilson and Goldberger added a small portrait to the left of the center one in the form of the Unipolar limb leads. On the right side, the portrait of the unipolar precordial leads was hung. Vector cardiography and ballistocardiography were to come later. Thus, for a time, the "portraits" were complete and similarly was the cardiologist. This time interval,

Address given at the Founders Day banquet of the Phi Chi medical fraternity, University of Minnesota, February 13, 1957.

however, was relatively short, as compared to that which had preceded the initial tremor.

Forssman, in 1929, in a remarkable demonstration of courage, passed a ureteral catheter through one of the veins of his right arm until the tip lay within the right atrium. It is also remarkable that this investigator performed the first attempt at selective angiocardiology, by injecting an organic iodine compound, uroselectan, through the catheter in an attempt to visualize the pulmonary vessels. Although unsuccessful, the important impact of this man's unusual and remarkable foresightedness needs no further elaboration. This is attested to in that it was not until 1941 that Cournand described the introduction of a radiopaque catheter into the auricle of a human subject. Three years previous to this, Robb and Steinberg published their results of the intravenous injection of organic iodine compounds for the purpose of delineating the heart and great vessels. Thus, within three years of each other, two of the most important diagnostic techniques available to us were given their initial clinical impetus. Because of their highly technical and somewhat hazardous nature, (and one might in truth, jest, their high cost,) these additional portraits were not immediately available nor earnestly sought for by the cardiologist. They were not ignored, but in passing discussion, it was apparent that they were regarded principally as "tools in the hands of researchers," and as such, would be found only in university centers. This was as it should be, in a sense, until the complete clinical applications had been evaluated and techniques perfected: one wonders at the length of time that these may have lain clinically dormant, had not a guest, not usually present before, knocked and requested admission into the house of cardiology. That this guest was dressed in a white scrub suit was remarkable, indeed, but even more astounding, he was conspicuous by the absence of the usually prominent stethoscope and EKG machine. In their stead, this visitor was seen to have a single instrument grasped tightly in his right hand. This was a scalpel. In such manner did the visitor enter into the hallowed premises of the cardiologist and internist. One might theoretically state that he was not as well received as was the prodigal son. It soon became apparent that this individual was also a portrait painter of note, as evidenced by the initial portraits of intracardiac

and extracardiac surgery. Thus, in 1944, Blalock, Gross, and Crafoord successfully attacked coarctation of the aorta. The year 1945 saw Blalock attack pulmonary stenosis by creation of his shunt anastomosis, and this year also saw Bailey open up the field of valvular surgery by his direct attack on a stenotic mitral valve. One year later, Potts gave a description of his procedure. Brock and Sellers, in 1948, successfully attacked the stenotic pulmonary valve.

The surgical entrance into the treatment of cardiovascular disease did not take place overnight. Many hours, weeks and months of tedious and arduous experimental surgical procedures were tried and tested in the dog laboratory. Only as a result of this was human surgical intervention made possible. This combination of the dog laboratory and the operating table began to unfold to the eyes of the surgeon the physiologic and anatomic aberrations of the various acquired and congenital cardiac disease states. A greater appreciation and knowledge of the pathologic physiology followed, which began to become manifest in the greater number of portraits hung on the wall of the house of cardiology by the man with the scalpel in his hand. It also became apparent that of the many guests present, his voice began to become more dominant and authoritative. That this should happen, in a sense, was inevitable, since who was in a better position to evaluate and correlate at first hand not only the altered pathologic anatomy, but the pathologic physiology as well?

To the cardiologist, such a dominant voice in his own house became a challenge. Although many of the surgical steps described above were accompanied by equally important medical steps, this was not prevalent at first in regard to the number of cardiologists. Thus cardiac catheterization, with its valuable information of cardiac hemodynamics, was utilized more and more as a routine clinical diagnostic tool and not solely as an investigative procedure of research nature. The cardiologist began to integrate, as well, the results of peripheral and central angiocardiology with his other studies. He began to return the visits of his surgical colleague by being present at the operating table to see with his own eyes the gross anatomical variations attendant upon the different types of congenital and acquired diseases of the cardiovascular system. He became an integral part of the team, con-

tributing to the preoperative and postoperative management of the patient. In addition to the preliminary diagnostic procedures he had instituted in order to present to the surgeon the exact diagnosis, he also detailed the physiologic consequences of such disease, in the form of accurately determined scientific data. In such manner did men like Cournand, Dexter, Bing, Wood, and others enhance, establish, and cast the cardiologist in a scientifically clinical mold.

In closing, let us retrace and simplify this process of maturing of the cardiologist. As we survey the various portraits which are hung in their respective positions on the four walls of the house of cardiology, it becomes apparent that each portrait represents a part of the whole. That is, the portrait can not be complete until the assembling process has occurred. Thus, we must go back to that portrait which had been taken down, depicting the cardiologist at the bedside. The fundamentals of the cardiologist are still there, i.e., the potentiality of a trained mind to see the patient and to evaluate the sounds which the stethoscope conveys to his ears. We see the final maturing of the cardiologist as a complete and finished portrait, when the basic understanding of electrocardiography, cardiac roentgenography, cardiac catheterization, angiocardiology, technique of corrective surgical procedures, as well as preoperative and postoperative cardiac management as represented by the small portraits, are integrated with the basic large portrait mentioned above. Then can the large portrait truly hang once again in its revered place on the mantel above the fireplace in the house of cardiology.

WM. F. MAZZITELLO, M.D.

BOOKPLATE LETTERING AND REFERENCES

Lettering

This is the sixth and last of the articles on bookplates. The earlier ones told of their history, the customs of collecting and exhibiting, their preservation, size and material, and the various kinds of plates for their printing.

If you are making the design yourself, remember the one word "accuracy." This is perhaps more necessary in the making of bookplates than in any other line of art. Harold W. Kearney, in an article in the *Bookplate Chronicle*, says,

"Take every precaution to insure accuracy. If lines are to be parallel see that they are parallel to the last infinitesimal fraction of a hair's-breadth. Do not cherish the false hope that little inaccuracies will be lost in the general effect; they are almost as ineffaceable as the sins that are chalked against us in the book of the recording angel, and will point accusing fingers at you forevermore. You will find this particularly true of your lettering."

If you are not to make the drawing yourself, then find the artist who can do it most to your liking. He will charge you whatever he may think right, perhaps \$25.00, perhaps \$200.00. You say, "So much for such a little thing?" Yes, but remember it may be a gem. And then again the designers have no corner on the making of bookplates. You may start in and do it for yourself.

References

Books easily understood, and well illustrated with examples are:

- "Bookplates for Beginners" by Alfred Fowler, Kansas City. 1922.
- "Some American College Bookplates" by Harry Parker Ward, Columbus. 1915.
- "The Book of Artists' Own Bookplates" by Ruth Thomson Saunders. Saunders Studio Press, Claremont, California. 1933.

The American Society of Bookplate Collectors and Designers was founded in 1922, and has published Year Books since 1923. A printed Index of these exquisite booklets "1923 to 1950" has been issued. Membership is limited and is obtained by sending name and address to the Secretary with three prints of your bookplate, or bookplates, with a statement as to the name of designer, engraver or etcher and year produced, accompanied by the annual fee of \$4.00. There is no initiation fee. Annual fee includes Year Book and *Bulletin* containing an exchange list. Carlyle S. Baer, Secretary-Treasurer, 3333 McKinley Street, N.W., Washington 15, D. C., is the person with whom to correspond. Membership includes people of other countries. This society does not hold exhibitions of the current work of its members as did its forerunner, the American Bookplate Society, in New York from 1916 to 1926. Instead it puts their work into a special collection at the Division of Fine Arts, Library of Congress, Washington, D. C., and publishes the Year Book "of information of interest to members with reviews of the work of bookplate artists with examples of their work."

its exhibitions from the time of its organization, 1925, annually for twelve years (1936 inclusive). This was in the period between World War I and World War II, and then conditions made it impossible to continue.

Because of the fact that bookplates have permanence, and a recognized place in the field of art, young designers can submit their original drawings under the division "Black and White" in almost any art exhibition in the United States, and have them judged by an art jury of distinguished persons. Awards from such juries are worth a great deal to a designer who is building recognition for his or her work. Even if an award is not received, it is an honor to have one's work accepted by such a jury of admissions, and the young artist who is supposed to exhibit once a year, somewhere, in order to maintain professional standing, has the satisfaction not only of doing creative work but of meeting art requirements successfully.

CONFESSIONS OF A HOBBYIST

Color Printing

Making a really fine color print—not the 75-cent kind with false colors and fugitive dyes—is a one-way trip to a padded cell. When you've tried it, you think of Mr. Eastman's charge of \$25 up, not as robbery, but as philanthropy. The cost is not in the materials, but in the time and the skill, for the process is a combination of chemistry, physics, mathematics, optics, and delicate and accurate manual dexterity. If the transparency from which you work is 35mm., the cell needs double padding. For fifteen years, I've been making such prints from transparencies of wildflowers, and now—sometimes—they come out gorgeously. Sometimes, not!

The process is called "double-masked dye-transfer." Two diffuse negatives, called "masks," are first made from the transparency, one through a red filter and one through a green filter. These are taped in register with the transparency, the first while red and green filter "separation negatives" are being exposed, and the second while the blue filter "separation" is exposed. The function of the masks is to cut off the overlap between the spectral curves of the three dyes, thus purifying the colors, especially the reds and greens. Each filter, in turn, blocks out one of the three

primary colors—blue-green (cyan), magenta, and yellow. Separations and masks must be processed in complete darkness, and the blue-filter separation is developed three minutes more than the other two. From each separation, by enlargement, is made a "matrix," exposed through the back of a special film. In development, the matrices are "tanned" so that the silver image is impervious to considerable heat. The developed matrices are flooded with water at 120 degrees, and this melts off the gelatine where there is no silver image, leaving a "relief." The three reliefs are dyed with the three primary colors, cyan, magenta and yellow. The three dyed images are then transferred, successively, in register, to specially prepared paper. The result is a color print, closely approximating the transparency. Exposure times are determined by densitometer readings, and calculated mathematically. Timings and temperatures must be exact. A small error in timing, density measurement, calculation, temperature, or manipulation results in a cast, if not a predominance, of false color. Done precisely, the results are beautiful. The first time I tried this process, it took twenty-two hours to make a very bad print. Now, including drying times, it takes about five hours. After the matrices are made, duplicate prints can be made in about half an hour. It is a fascinating and challenging process, frequently frustrating and depressing, but sometimes thrillingly rewarding.

JOHN DEQ. BRIGGS

SAFETY GLASS IN YOUR CAR

Safety glass was one of the early safety devices built into a motor car. After nearly thirty years' acquaintance with it, the average car owner thinks very little about it, how it functions, how it has been improved from year to year, and how it has taken on added functions of providing comfort and greater quantity of vision. Safety glass is considered as commonplace as brakes, bumpers, and seat cushions.

But to get the utmost value in personal comfort and effectiveness in driving your car, it is well to know something about safety glass.

There are two kinds of safety glass used in most modern cars—(1) laminated safety glass in which a sheet of polyvinyl butyral plastic is sandwiched between two panes of glass and the whole subjected to a cycle of heat and pressure in an autoclave making it into a transparent unitary

structure, which clings together even if fractured, and which yields with its tough plastic interlayer if struck by a heavy object. Then there is (2) solid safety glass which is used largely on backlights of cars, sometimes in sidelights and smaller wind vents, which is a heat-tempered glass achieving five to six times the strength of ordinary glass and added toughness and flexibility through the molecular action achieved in a case hardening treatment.

Laminated safety glass may be made from two pieces of ordinary window glass or, in a quality product, from two pieces of $\frac{1}{8}$ -inch polished plate glass which give it the characteristics of a precision optical unit. The solid safety glass usually starts with quarter-inch plate glass but may be made, as it is in some foreign cars, of thick window glass. Laminated safety glass is by very nature also more expensive to manufacture than solid safety glass.

Plate glass is a product superior to window glass and has been so recognized down through several centuries. However, even polished plate glass has been greatly improved in recent years.

From the very early days of American motor car development, safety plate glass has been specified for all windshields because of the importance of maximum forward vision.

State codes require an identifying etch on each piece of safety glass. Only where this etch contains the letters P-L-A-T-E, either as a separate word or as part of a coined word, is the consumer assured of getting top quality glass. That is all the car owner needs to know about the intricate manufacturing techniques and the immense amount of technology which has gone into the modern safety glass. If he sees the word "plate" on the label, he knows he has the best and most distortion-free product.

Some motor car manufacturers use safety plate glass all around the car in every unit of glass. Others use some window or sheet glass for side lights. Quite universally in America, safety plate is used for the windshield and solid safety plate for the rear light.

In the very process of making window glass or as it is known in the trade, sheet glass, there is a certain amount of resulting waviness or distortion in the glass—not nearly so much as in the old hand-blown window glass days—but substantial as compared with modern plate glass. For the purpose of a window—to let in light, to

open for ventilation, and to keep out wind and weather—slight distortions are not objectionable because nature and seasonal views are mostly static. For good vision, as in a picture window, a store front or a fine mirror, one always uses polished plate glass.

In a moving automobile, from which passengers always are looking outward to view rapidly passing scenery, the difference between safety sheet and safety plate glass is at once apparent.

Side windows of automobiles may induce in auto passengers a temporary condition resembling the eye-defect known as aniseikonia, explained by the late Dr. Adelbert Ames, Jr., and Dr. Kenneth N. Ogle, at Dartmouth College. This defect results in a difference in size of images seen by each eye.

"To persons with this defect, a curbstone may appear higher than it is, flat surfaces may not look level, objects may seem closer or farther away than they are," it was explained. "Headaches, nausea, eye strain and dizziness are not uncommon symptoms, depending, of course, upon the degree to which the sufferer is affected."

Scientists have found that the waves in sheet glass, when used in side windows of a moving motor car, may produce a temporary condition closely resembling aniseikonia. This is not true of safety plate glass.

Therefore, for the best possible visual conditions for motoring, one first should examine the windows in his car and insist upon a motor car with all important windows officially labeled safety plate glass.

WILFRID HIBBERT

Libbey-Owens-Ford Glass Company

PHI BETA PI MAN OF THE YEAR

Walter A. Fansler, M.D., Minneapolis, has been chosen Phi Beta Pi Man of the Year by the Phi Beta Pi National Medical Fraternity. Each year, this organization selects one of its outstanding members for this honor. The October issue of the national publication of this fraternity, *The Quarterly*, honors Doctor Fansler and his many achievements as physician, teacher and a builder of the Fraternity. This includes an interesting bibliographic sketch depicting his career up to the present.

In the fraternity world, Doctor Fansler helped establish several chapters of Phi Beta Pi in medi-

President's Letter

SOCIAL SECURITY FOR PHYSICIANS

The problem of the old age and survivors' insurance administered by the Federal Social Security Administration, as this problem relates to physicians, has been controversial in medical circles for some years. Since Bismarck introduced socialized medicine in Germany three-quarters of a century ago, the spread of socialized medicine by means of extension of so-called social insurance has been ever-present in Western civilization. One nation after another has yielded to the clamor to extend the compulsory system of taxation called "social insurance" to finance a program of medical and hospital care.

The history of the development of this field in foreign countries has alerted members of the American medical profession to the consequences of the Federal Social Security program. Most physicians who conduct their own private practices of medicine do not retire, nor do they have any intention, during their early professional lives, of retiring at a given age. Currently, about six physicians of seven in the age group between 65 and 75 years are engaged in the active private practice of medicine. Since, as we have said, most physicians in this category do not retire, the tax imposed upon them by extending old age and survivors' insurance to them would be unjust and unreasonable. That is, they would be required to pay the tax in question long after most gainfully employed persons in their respective occupations have ceased to pay it and have begun to receive their Federal benefits.

Actually, the program of social security is not an "insurance" program. Retired beneficiaries of old age and survivors' insurance, as of December, 1952, have received, and would receive, on the average, pension benefits equal to approximately \$24 for each 50 cents paid during the working years of their lives. By the amendments in 1954, this amount has been raised to \$30.

Physicians, as a group, do not seek Federal gratuities. In preference to compulsory inclusion under the Social Security Act, members of the medical profession are giving their active support to the Jenkins-Keogh bills. These bills would amend the Federal internal revenue code so that self-employed physicians and others would have the same tax-deferment advantages on the amount set aside for retirement as are now enjoyed by officers and employees of corporations, associations and others. The bills would provide tax incentive for the acquisition of prepaid pensions for all who are willing to save. It is proposed that some tax exemption be allowed on money which self-employed persons invest in the pension to provide for their future.

The equitable aspect of this idea is that most persons in effect already enjoy such tax exemption. That is, the money paid by an employer to workers' pension funds is usually regarded as a cost of doing business. This money is not taxable in respect to either employer or employee. Great Britain's budget of 1956 contains such a provision. President Eisenhower has endorsed the idea.

PRESIDENT'S LETTER

Physicians, generally, by no means are all of one mind in regard to this problem. The question has come before the House of Delegates of the American Medical Association on several occasions. The most recent action was taken at the midyear meeting in Boston, November 29 to December 1, 1955, at which a resolution was passed to provide for a survey of the medical profession, by state societies, on the subject of the Social Security Act. In this resolution was the recommendation of the House of Delegates of the American Medical Association that individual state societies poll their entire membership on this question.

At that time, the House of Delegates re-affirmed its opposition to the compulsory inclusion of physicians on the Social Security rolls, but further resolved that the House of Delegates was not in opposition to the voluntary inclusion of physicians in the Social Security system.

Consequently, on or about May 1, 1956, all the members of the Minnesota State Medical Association received a card asking their opinion on this problem. Within two weeks after the cards had been sent out, 65 per cent of the membership replied in a manner which indicated an overwhelming trend in favor of voluntary coverage. An analysis of the replies received at the end of one week indicated that only 12 per cent of the physicians favored compulsory coverage, 61 per cent favored voluntary, and 27 per cent opposed any type of Social Security coverage. This trend continued as the replies were returned.

After these replies had been analyzed, and after a long discussion of the subject, the House of Delegates decided to take no action upon the resolution which had been introduced into the House of Delegates and which read as follows: "Be it therefore resolved that the House of Delegates of the Minnesota State Medical Association in session at Rochester, May 21, 1956, go on record as officially opposing the extension of the Social Security benefits to the physicians of the medical profession on either a voluntary or a compulsory basis and that the matter be returned to the various county medical societies for careful, thoughtful consideration."

This action apparently was misunderstood in many quarters. It was evident that the majority of physicians favored voluntary coverage by Social Security insurance. It was also evident that the vast majority opposed compulsory coverage. Because of this confusion, it seemed wise for the Minnesota State Medical Association to conduct another poll. Hence, soon after January 1, you will receive cards in which you are asked to express your opinion. I trust that when the returns from this canvass are recorded, everyone will understand very clearly where the physicians of Minnesota stand in regard to Social Security insurance for physicians.

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is written in a cursive style with a large, looping initial "J" and a long, sweeping underline.

President, Minnesota State Medical Association

HOSPITAL AND SURGICAL CARE THROUGH INSURANCE COMPANY POLICIES

There were 66.3 million persons covered for hospital expenses at the end of 1956 through individual and family health policies and through group insurance programs. This represents a 79 per cent increase over the 1950 total of 37 million.

In 1954, there was an increase of 5.9 per cent over 1953 in the number of people covered, the percentage gain in 1955 over 1954 was 7.9 per cent, and the rate of growth in 1956 over 1955 was 11.1 per cent.

Surgical expense insurance included some 63 million persons covered in 1956, compared with the 1950 total of 33 million, an increase of 91 per cent.

The number of people with insurance policies covering surgical expenses during the past three years increased as follows: 1954 was 4.6 per cent over 1953; in 1955 the increase was 7.3 per cent over 1954; and 1956 recorded a rise of 11.2 per cent in the number of people protected over the comparable period for 1955.

Regular medical expense coverage, providing for doctor visits for non-surgical care, rose 281 per cent in the number of people covered between 1950 and 1956, for a total of 29.8 million persons as compared with 7.8 million in 1950.

In 1954, regular medical expense insurance increased 12.9 per cent over 1953, and a rate of growth of 20.8 per cent between 1954 and 1955. In 1956, the increase in the number of people was 18.9 per cent over 1955.

Major medical insurance led all other forms of coverage in percentage of increase. Medical expense policies help cover the costs of serious, or catastrophic illness, including hospital bills, physicians' charges and other medical care services, and are available alone or as a supplement to the other types of expense policies.

At the end of 1952, there were some 689,000 persons in the nation with major medical coverage. In the four years since, this form of health insurance rose 1188 per cent, for a total in 1956 of 8.9 million persons.

Recent estimates indicate that as of May 1, 1957, the total exceeded 10 million persons.

RECORD NUMBER OF HEALTH-MEDICAL BILLS ENACTED BY 85TH CONGRESS

A record total of 441 health-medical bills were introduced in the 85th Congress. Action was deferred on a majority for a variety of reasons, including desire for more extensive hearings, economy, and possible inclination to save popular appeal bills for an election year, second session. The following is a résumé of health legislation enacted:

Doctor Draft Extension (P.L. 85-62)—Gives Selective Service authority until July 1, 1959 (when both this amendment and the regular draft expire) to call certain physicians up to age 35 for military service. Only those under age 35 with obligations under the regular draft and who have been deferred for any reason may be called. Defense Department, meanwhile, says it is getting enough medical school graduates as reservists to preclude use of the new law at this time.

Medical Research (P.L. 85-67)—Another early enactment was the fiscal 1958 budget for the Department of Health, Education, and Welfare. Congress voted \$2,503,130,381 for all HEW programs, including record high totals for medical research through the National Institutes of Health.

Vendor Medical Payments (P.L. 85-110)—With regard to federal participation in the categorical welfare programs, it gives states the choice of either (a) using federal funds for vendor medical payments within the \$60 a month per recipient maximum or (b) establishing a single medical vendor payment financed by federal funds which were set by a 1956 law at one-half of \$6 a month per adult and one-half of \$3 per child, to be matched by states. States can also continue to make direct payments to recipients for medical and subsistence expenses.

The Minnesota Department of Public Welfare has chosen the latter program, (b) with the \$6.00 fund being used for direct vendor payments for

nursing home care. Payments for all other medical care expenses are made to the recipient. The Department adopted this method of payment to enable Minnesota to receive the maximum amount of federal funds obtainable. A proposed amendment considered by Congress and strongly supported by several states, including Minnesota, would have permitted vendor medical payments from both the \$60.00 and the \$6.00 funds, but was rejected by Congress ostensibly for purposes of economy of expenditure of federal funds.

Disability Freeze Extension (P.L. 85-109)—A new deadline of July 1, 1958 is established for disabled persons covered under social security to apply for full retroactivity under the disability freeze passed in 1954. Applications filed by next July will allow workers to count the full period of disability, provided they were eligible for disability benefits at the time the disability was incurred. After next July 1, any period of disability established for a worker cannot begin earlier than one year before the application is filed.

Indian & Non-Indian Hospitals (P.L. 85-151)—Authorizes federal funds to help build non-profit or public hospitals and diagnostic or treatment centers on or near Indian reservations; the extent of federal contribution will be determined by the percentage of care given eligible Indians. The facilities have to agree to care for both Indians and non-Indians.

Vocational Rehab Traineeships (P.L. 85-198)—Extends from two to three years the maximum period of time over which the federal government can pay for partial financing of traineeships in physical medicine and rehabilitation. It amends the Vocational Rehabilitation Act which was expanded in the 84th Congress.

Vocational Rehab Planning (P.L. 85-213)—Amends the Vocational Rehab Act by extending the time federal funds may be used for planning, preparing and initiating expansion of programs in the states.

Codification Veterans Laws (P.L. 85-56)—Brings into a single code all veterans benefit laws, including those providing for hospital and medical care.

Poultry Inspection (P.L. 85-172)—Under this

law, federal inspection of poultry moved in interstate commerce becomes compulsory.

Military Nurses Incentives (P.L. 85-155)—In line with earlier efforts to make careers in the military more attractive, Congress passed this law improving career prospects for military nurses by making more and higher ranks available.

MEDICAL SOCIETIES TO BASE FEES ON PRICE INDEX

Eighty-five per cent of the 507 physicians in Long Beach, California, have adopted the Physicians Health Plan. According to the terms of the plan, physicians will charge fees based on the cost-of-living index of the Bureau of Labor Statistics.

For instance, if the index rises appreciably, medical and surgical fees will rise proportionately. If the index drops, fees will be lowered accordingly. Variations of less than 5 per cent will be ignored.

The group has adopted the California State Medical Association's "relative value" fee guide which bases the relative value of specific medical and surgical procedures—one in relation to another—rather than on a fixed dollar value.

The four schedules, medicine, surgery, radiology and pathology, include approximately 1,200 procedures. By accepting this schedule, doctors participating in the Long Beach Physicians Health Plan will now be paid rates about 25 per cent higher than they have been receiving since 1955 when the plan was started.

The Long Beach Plan has set a local unit value of \$5.00 which all participating physicians have accepted as constant. For example, a routine office call after the patient's first visit is rated as one unit; house calls, two units; and night calls, two-and-a-half units.

Accordingly, the plan pays \$175.00 for an appendectomy, valued at thirty-five units under the state code, and member-doctors agree not to charge more.

The Long Beach Plan which was established as a service program without income ceiling or age limitations, offers medical, surgical and hospital benefits. The Plan has Blue Shield backing, but it can offer wider coverage than the state Blue Shield Plan (California Physicians' Service), which has \$4,200 and \$6,000 income ceilings in an area served by the Kaiser Foundation Health Plan and other plans without income limits.

The Long Beach Plan is now open to any employee group of twenty-five persons or more. In its early years it was limited to groups of 100 or more. About 5,000 persons are now covered—an increase of 90 per cent in the last year.

Regardless of income, the subscriber pays no additional fees to physicians participating in the Plan and is free to go to the doctor of his choice.

PHYSICIANS VOICE OBJECTIONS TO MEDICARE "RED TAPE"

Physicians rather than Medicare dependents are the chief source of complaint to the United States Defense Department.

The Department's first interim report disclosed that physicians objected to the many forms to be filled out in conjunction with Medicare cases.

Another complaint cited by physicians was the constant necessity of checking with Medicare manuals to determine whether or not a certain type of care is covered.

The Defense Department comments that physicians are performing "admirably" even though many object to "government intervention," full-service contracts, and the load of paper work.

The report further disclosed that 127,902 physician claims averaging \$68.84 and 103,595 hospital claims averaging \$103.60, were filed in the six-months period ending July 1, 1957.

A special eight-state study included in the report showed that physicians handled more maternity cases than any other type, at an average physician-hospital cost of \$224. Tonsillectomy, at \$113 per case, was also high on the list, followed by respiratory infections and gynecological conditions.

VA HOSPITAL NEEDS CITED

Congress may soon be asked to decide whether facilities of VA hospitals are to be expanded to care for non-service-connected cases.

Veterans Administration officials point out that patient loads are relatively stable at present. The average daily patient load in all hospitals is 112,499, with 109,579 patients in VA hospitals and 2,920 in non-VA hospitals. It is estimated that there are more than 22,000 eligible hospitalization applicants awaiting admission.

Service-connected cases account for one-third of the daily VA hospital load and non-service-connected cases, two-thirds. Present VA policies base non-service-connected admission on the basis of extra beds not required for service-connected cases.

PHI BETA PI MAN OF THE YEAR

(Continued from Page 811)

cal schools from coast to coast. He has held the highest offices in this organization including that of Supreme Archon and Supreme Editor of *The Quarterly*. At the present time, he is Chairman of the Expansion Committee and a member of the Board of Trustees.

In the medical world, he has gained an international reputation as surgeon and author. Presently, he is Clinical Professor of Surgery and Director of the Department of Proctology at the University of Minnesota. He is a founder and Past President of the American Board of Proctology, a certifying group for specialists in this field. In addition, a few of his achievements include: Fellow and Past President, American Proctologic Society; Honorary Fellow, Philadelphia Proctologic Society and Fellow of the American College of Surgeons.

In Minneapolis, among other interests, Doctor Fansler is a member of the Minneapolis Academy of Medicine, is an enthusiastic Rotarian and a Guarantor of the Minneapolis Symphony Orchestra.

WILLIAM T. SMITH, M.D.

EVALUATION AND MANAGEMENT OF MINOR CONTUSIONS OF THE EYE

(Continued from Page 765)

Conclusion

A careful analysis of any minor contusion of the globe will undoubtedly show the presence of two to six of the many sequelae mentioned—all obviously related anatomically to one another, and stretching from the conjunctiva, cornea and anterior chamber to the iris, the iris root, ciliary body, zonule, lens, ora serrata, vitreous, retina and choroid. The most important effects of contusion are the tears and lacerations of the anterior and posterior uveal tract with hemorrhage, subluxation or dislocation of the lens and damage to the retina.

Treatment of most of these lesions is confined to bed rest, sedation, and bandaging of the eyes until the danger of hemorrhage is past.

For medicolegal reasons the importance of a concise but detailed history and the recording of all pertinent findings and observations is stressed.

Committee Action

Hospitals and Medical Education Report for the Year 1956-1957

The following is an abridgment of the report submitted to the Council and to the House of Delegates of the Minnesota State Medical Association at the annual meeting of the Association, May 13 to 15, 1957. The committee held one meeting, on December 6, 1956, in Minneapolis.

Hospital Construction in Minnesota

The committee noted with pleasure the report of the Minnesota Department of Health indicating that during 1956 six new hospitals in the state were completed while seven more were under construction, that nine hospitals had completed building programs resulting in additional or improved facilities, while similar building programs were under way in nineteen others, and that public health centers were under construction in both Saint Paul and Minneapolis. Sixteen of the programs were accomplished with the assistance of the Hill-Burton program, the remainder without such assistance. Altogether, 1266 new hospital beds will be provided by these projects, including 1119 actual additional beds and replacement of 147 beds formerly housed in nonfire-resistant structures.

During the year, ninety-nine general hospitals, admitting more than 80 per cent of all patients admitted to general hospitals, performed routine admission chest x-rays.

Attention should be called to the fact that, although Minnesota has received slightly less than \$20 million in Hill-Burton funds since the program started in 1948, the total estimated volume of construction completed, now under way, or in the planning stage, approximates \$250 million in the field of hospitals and related facilities.

Medical Students

In June, 1956, 116 students, and in June, 1957, 110 students were awarded the Doctor of Medicine degree by the University of Minnesota. The number of students admitted to the Medical School in September, 1956, was 127. Approximately the same number will be admitted in September, 1957.

Graduate Medical Training

The State of Minnesota continues to occupy a leading place nationally and internationally in graduate training in medicine, almost all of which is carried out under the Graduate School of the

Hospital Construction in Minnesota
Medical Students
Graduate Medical Training
Continuation Medical Education
Nursing
Medical Technology
Laboratory Aide Program

University. During the 1956-57 academic year, 1,037 graduate students were enrolled in the basic medical sciences and the clinical specialties of medicine. This figure includes 591 graduate students enrolled in the Mayo Foundation program in Rochester and 446 enrolled in the Medical School program in Minneapolis, which utilizes for graduate training in the clinical fields not only the University of Minnesota Hospitals, but also Minneapolis General Hospital, Minneapolis Veterans Administration Hospital, Ancker Hospital in Saint Paul, the Gillette State Hospital, and several private hospitals in the Twin Cities. The demand for graduate training in various specialties of medical practice is somewhat less than a few years ago, but the reputations of the University of Minnesota Medical School and the Mayo Foundation attract large numbers of applicants in most areas. Vacancies, however, continue in most of the basic medical sciences as well as in psychiatry, rehabilitation, and anesthesiology.

Continuation Medical Education

The Department of Continuation Medical Education, which presents each year a series of continuation courses for physicians, continues to provide the practicing physicians of Minnesota with an opportunity to review significant fundamental material and to learn of important advances in medical practice. The unique facilities of the Center for Continuation Study provide an atmosphere especially conducive to learning.

During the 1955-56 academic year, 1,304 physicians attended twenty-two courses at the Center for Continuation Study. All but four of these courses were intended primarily for physicians engaged in general practice. During the 1956-57 academic year, twenty-one courses, fifteen of them primarily for general physicians, have been or will be presented. Preliminary figures indicate that attendance during the current academic year will surpass that of last year. Since the fall of 1955, in addition to courses presented at the Center, regional seminars for physicians have been presented in Alexandria, Marshall, Fairmont, Chisholm, New Ulm, and Hibbing by the University, in conjunction with the Minnesota State Medical Association and local medical groups.

The Department of Continuation Medical Education also is responsible for the planning and

presentation of continuation courses for nurses, medical technologists, and dietitians. These programs continue to be well received.

Nursing

The provision of adequate nursing remains a difficult problem in certain areas of the state, particularly those in which new hospitals have been constructed or existing hospitals expanded. Minnesota, however, is distinctly above the national average in the number of nurses per 100,000 population. A survey showed that 7,588 professional nurses were actively engaged in nursing in Minnesota during 1956. Of these 5,317 were employed in hospitals and similar institutions, 693 were performing private duty nursing, 432 were engaged in public health nursing, 361 were employed in office service, and 785 in other fields of nursing.

Seven of Minnesota's twenty-eight schools of nursing have four-year degree programs. Although Minnesota ranks nineteenth in population, only seven states have more nursing students. More nurses are graduated by Minnesota schools than by the nursing schools of any of the neighboring states.

Practical nursing training is carried chiefly by vocational education departments of school systems in conjunction with local hospitals. On January 1, 1957, Minnesota had fourteen schools of practical nursing and four additional schools are expected to open during the year. A new development in Minnesota is the preparation of nonprofessional nursing personnel for the care of psychiatric patients.

Education for advanced professional nursing—administrative, teaching, supervisory, and public health nursing—is centered in the University of Minnesota, which trains more teachers of nursing than any other institution in the country.

Rural community nursing is a part of the basic educational program of many schools of nursing in Minnesota. Experience for students is provided through affiliation with community hospitals outside the metropolitan areas of the state. Schools of nursing in Minneapolis, Saint Paul, and Duluth assign students to community hospitals in Bemidji, Benson, Fairmont, Grand Rapids, Hibbing, Litchfield, Pipestone, Sauk Centre, Sleepy Eye, Stillwater, Thief River Falls, and Worthington. The University of Minnesota provides the direction and co-ordination of this program.

Special educational nursing services in the state include extension classes, workshops, and institutes. Since 1951, the Minnesota State Student Nurse Scholarship Act has provided more than 1,400 scholarships. A survey of students graduated in 1955 indicated that 65 per cent are employed in counties of more than 100,000 population, while 31 per cent are serving in smaller communities. Four per cent failed to respond to the questionnaire.

Medical Technology

Although in the past few years the number of students completing requirements for the four-year degree program in Medical Technology has been below normal, the present indication of slight increases in the number of students in this program is encouraging.

Last fall the increase in numbers of students transferring into the third year at the University from the junior colleges within the state was a hopeful sign. In 1956-57, fourteen students transferred here while the year before only two students transferred at the third year level, directly contributing to the present small senior class.

The increasing need in the state for the services of the professional graduate medical technologist serves to emphasize the present critical shortage of laboratory personnel. Continued and vigorous efforts toward recruitment of students are urgently recommended.

Laboratory Aide Program

During the past year the Laboratory Aide Program has been expanded by the inclusion of four additional hospitals outside the Twin Cities area for clinical training of students. Newly participating hospitals include Our Lady of Mercy Hospital, Alexandria; Miller Memorial Hospital, Duluth; Virginia Municipal Hospital; and Community Memorial Hospital, New Prague.

At present, twenty-one students are being trained in technical laboratory procedures at twelve hospitals in the Twin Cities and eight institutions outside the Twin Cities. Of the seven students trained during 1955-56 in the hospitals outside the Twin Cities, all are currently employed in hospitals and doctors' offices outside the metropolitan area.

General awareness of the Laboratory Aide Program appears to be increasing, and enrollment in it may be expected to rise. Future expansion of the program should be contemplated if necessary financial support is available.

CONFIRMED THERAPEUTIC UTILITY

Pro-Banthine® “proved almost invariably effective in the relief of ulcer pain,

*in depressing gastric secretory volume and in inhibiting gastrointestinal motility.”**

“Our findings were documented by an intensive and personal observation of these patients over a 2-year period in private practice, and in two large hospital clinics with close supervision and satisfactory follow-up studies.”*

Among the many clinical indications for Pro-Banthine (brand of propantheline bromide), peptic ulcer is primary. During treatment, Pro-Banthine has been shown repeatedly to be a most valuable agent when used in conjunction with diet, antacids and essential psychotherapy.

Therapeutic utility and effectiveness

of Pro-Banthine in the treatment of peptic ulcer are repeatedly referred to in the recent medical literature.

Pro-Banthine Dosage

The average adult oral dosage of Pro-Banthine is one tablet (15 mg.) with meals and two tablets at bedtime.

WORLD HEALTH ASSEMBLY TO MEET IN MINNEAPOLIS

The World Health Assembly, policy-making body of the World Health Organization, will hold its tenth annual meeting in Minneapolis, May 26 to June 14, 1958. At this first meeting of the assembly in the United States, an attendance of 400 delegates is expected, representing eighty-eight nations. Total attendance is expected to be 1,500, including the secretariat staff from WHO headquarters in Geneva, a staff from the U. S. State Department, and visitors and observers.

WHO, which was founded in 1946, following signing of the United Nations charter, has gradually absorbed existing international health organizations and is now established as a permanent agency of the UN. It is dedicated to the goal of helping all people attain complete physical, mental, and social well-being. For nine years it has waged an intensive war against malaria, tuberculosis, yaws, trachoma, and leprosy. It also gives technical aid to member nations, provides training opportunities for health personnel, disseminates health information, and fosters research on diseases.

FELLOWSHIPS AVAILABLE FROM AMERICAN FOUNDATION FOR ALLERGIC DISEASES

The American Foundation for Allergic Diseases announces their post-doctoral fellowships in research and clinical allergy for two years each. The stipend for the first year is \$4,500; second year, \$4,750; laboratory and travel expenses for two-year period, \$750.

Requests for applications should be sent directly to one of the following, in whose field the candidate would like to work: Dr. Colin M. MacLeod, Professor of Research Medicine, University of Pennsylvania, 820 Maloney Clinic, 36th and Spruce Streets, Philadelphia 4, Pa.; or Dr. Herman N. Eisen, Professor of Medicine (Dermatology), Washington University School of Medicine, 600 South Kingshighway, Saint Louis 10, Missouri.

Applications should be filed no later than December 15, 1957 with any of the above.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota are:

December 5-7	Fractures for General Physicians
January 6-11	Ophthalmology for Specialists
January 9-11	The Newer Drugs in General Practice
Jan. 30-Feb. 1	Emergency Surgery for General Physicians

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

NEW ORLEANS GRADUATE MEDICAL ASSEMBLY

The twenty-first annual meeting of The New Orleans Graduate Medical Assembly will be held March 3, 4, 5 and 6, 1958, with headquarters at the Roosevelt Hotel.

Eighteen outstanding guest speakers will participate, and their presentations will be of interest to both specialists and general practitioners. The program will include fifty-four informative discussions on many topics of current medical interest, in addition to clinicopathologic conferences, symposia, medical motion pictures, round-table luncheons and technical exhibits.

The Assembly has been officially approved for Category I by the Commission on Education of the American Academy of General Practice. Thirty hours of formal credit will be allowed for attendance at this meeting.

Following the meeting in New Orleans, arrangements have been made for a postclinical tour to Mexico City, Cuernavaca, Taxco and Acapulco, leaving from New Orleans on Friday, March 7, and returning on Tuesday, March 18.

Details of the New Orleans meeting and the post-clinical tour are available at the office of the Assembly, Room 103, 1430 Tulane Avenue, New Orleans 12, Louisiana.

NOW—EFFECTIVE STEROID HORMONE
THERAPY OF RHEUMATIC AFFECTIONS
WITH GREATER SAFETY AND ECONOMY

PABALATE[®]-HC

***Pabalate with
Hydrocortisone***

Clinical evidence indicates that, in Pabalate-HC, the synergistic antirheumatoid effects of hydrocortisone,

salicylate, para-aminobenzoate, and ascorbic acid achieve satisfactory remission of symptoms in up to 85% of cases studied

—with a much higher degree of safety

—even when therapy is maintained for long periods

—at significant economy for the patient

Each tablet of Pabalate-HC contains 2.5 mg. of hydrocortisone — 50% more potent than cortisone, yet not more toxic.

FORMULA

Each tablet:

Hydrocortisone (alcohol)	2.5 mg.
Sodium salicylate	0.3 Gm.
Sodium para-aminobenzoate ..	0.3 Gm.
Ascorbic acid	50.0 mg.

AGE: Two tablets four times daily.
Additional information on request.

Woman's Auxiliary

LIFE IN FORMOSA

The following letter which will undoubtedly be of great interest both to physicians and their wives was sent in by Mrs. Peter Pankratz, formerly of Mountain Lake, Minnesota, an active member of the Southwestern Minnesota Auxiliary. She and her husband are now stationed at the General Conference Mission in Taiwan, Formosa.

I promised quite some time ago that I would write to share with you some of the "on-the-fringe-of-things" here, but the minute someone hears the "peck-peck" of my typewriter, it's the signal for callers; they can hear that I'm home so I expect this will be in the composition room for several days.

We have been here now a bit over a year and it is "home" to us; there is beauty all around us—the ocean, the mountains, the friendly people! There is beauty, too, among the sordid that comes each day to the hospital, and we think things are a bit better than when we came.

The place is much cleaner and doesn't smell as awful; could it be that we have become conditioned? Maybe so. We hope it won't be too much longer until some teaching of good health habits takes hold and goes home from the clinic with these people, who, in their villages mostly live in shelters, along with ducks and chickens, turkeys and geese, a pig or two and the water buffalo which rates better care than the children in many cases.

Having seen the dirt floors on which babies sit, bare-bottomed, and where their hands, filthy dirty from whatever they investigate by which they are surrounded, invariably find their mouths or rub their eyes or their runny noses, I can understand why they are covered with sores, why their bellies are filled with worms. Not a very pretty picture, and how hard it is to take good care of such children, nurse them to beauty and then have to let them go right back into such living conditions again only to have it happen all over again!

And some are brought in so pitifully undernourished; one such was a little two-year-old girl who looked like she was only two great big dark eyes and the rest of her so wizened that she was called "little monkey." It took a while, but she grew into a real beauty; everyone played with her and missed her when her mother took her home. And then poor care and no food and too many other troubles in the home brought her back again. Once more she became beautiful and once more we let her go home with her irresponsible mother, and several days later our nurses' aides went to see her in another hospital where they had taken her, crushed and broken, hoping that we would not find out that her mother had trampled her most to death! She died. Our broken hearts must go beyond the confines of our hospital. Someone needs to "walk with and show them the way."

Our mobile clinic unit goes to the mountain villages one week of each month. It is made up of a doctor, a nurse or nurse's aide, a dentist or dental assistant, the hospital chaplain and the driver of the vehicle, the hospital ambulance. The doctor who has been helping, calls this his "spare-time work." He and his wife, both young and dedicated, from Norway, are working full-

time running a hospital for lepers in the southern part of this island. They are such an inspiration.

We have been taking pictures and have some quite nice ones—flowers and trees and rice fields and natives in and out of their colorful attire and other things, and one, a reflection which, when it is flashed on the screen, has everyone saying "Isn't that simply beautiful?" And really it is not beautiful; it is full of maggots, mosquitoes and pollution; it is a picture of shacks and out-houses sitting on the edge of a swamp; people live there. As a photograph, it is a superb reflection, but when one considers what is reflected, it is ugly and heart-breaking, full of vermin and germs. The people who live there, alive, yes, but you wonder why and what incentive, what force keeps them alive, slumming in such squalor. And they come and want to be made well so that they can go on living. We dare ask, where is the assistant to the assistant to the assistant to the sanitation engineer who will go to the "rice-roots" so that these people can live? We do not despair; we see cupfuls of milk dispensed and with each cupful, a cup of human kindness—that will be the measure.

Which brings me back to what I had planned to say first. Thank you to Mrs. Raymond Minge (of Worthington) and her committee and to everyone who helped with that drug shipment that came to us. There was much work to collecting, sorting and preparing the samples for overseas shipment; itemizing and tabulating was done so neatly. They were allowed in duty-free, be assured. They are being used and we are most grateful for your loving kindness which helps to fill that cup!

May you have a most wonderful time meeting together; I'm thinking of each one of you.

THEO PANKRATZ

SCHOOL OF INSTRUCTION IN MINNEAPOLIS

The Woman's Auxiliary to the Minnesota State Medical Association observed its annual one-day School of Instruction, Tuesday, October 8, in the New York Room, Hotel Leamington, in Minneapolis.

Dr. Walter C. Alvarez, editor-in-chief of *Modern Medicine* and twin-city newspaper health columnist, was the featured luncheon speaker for the occasion.

Dr. H. B. Sweetser, president-elect of the Minnesota State Medical Association, presented a luncheon greeting to the group.

Mrs. Paul C. Craig, Wyomissing, Pennsylvania, national president of the Woman's Auxiliary to the American Medical Association, spoke on "Health Is a Joint Endeavor."

The following presentations were included on the School of Instruction agenda: "American Medical Education Foundation," Mrs. M. D. Starekow, Thief River Falls; "Today's Health," Mrs. H. P. VanCleve, Austin; "Legislative Concerns," Mrs. L. Raymond Scherer, Minneapolis, and Mrs. L. R. Boies, Minneapolis; "Some Safety Angles," Mrs. Ralph Olson, St. Paul, Mrs. M. F. Fellows, Duluth, Mrs. Gilman Goehrs, St. Cloud, and Mr. Joe Neal, St. Paul; "A Public Relations Problem," Mrs. M. O. Wallace, Duluth; "Hospital Costs," Mr. Russell Nye, Minneapolis; "Rehabilitation," Mrs. Conrad Karleen, Minneapolis, Mrs. Wallace P. Ritchie, St. Paul, and Mrs. H. P. VanCleve, Austin. Mrs. L. P. Howell, Rochester, was the moderator.

Contributions for this column, including news and activities of state auxiliary societies and items of interest about members, may be sent to Mrs. A. B. Rosenfield, Woman's Auxiliary Editor, MINNESOTA MEDICINE, 2920 Dean Boulevard, Minneapolis, Minnesota.

In Memoriam

LEON C. COMBACKER

Dr. Leon C. Combacker, Fergus Falls physician for thirty years, died October 1, 1957. He was seventy-four years old.

Dr. Combacker was born in Osceola, Wisconsin, and received his preliminary education in the public schools of that community. He attended Michigan University, Ann Arbor, and received his A.B. and medical degrees from that institution. In addition, he did post-graduate work at the University of Minnesota.

His specialty was eye, nose and throat. Prior to his practice in Fergus Falls, he was located in Osceola, Wisconsin, for fourteen years and Stillwater, Minn., for one year. Dr. Combacker was a member of St. Luke's hospital staff in Fergus Falls, the American Academy of Ophthalmology and Otolaryngology, Park Region District and County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Mabel; two daughters, Catherine Hughes, Wilmington, Delaware, and Alice Olson, Zumbrota, Minnesota; four grandchildren; one brother, Howard R. Combacker, Minneapolis, Minnesota; and a sister, Mrs. G. M. Funne, Osceola, Wisconsin.

ELMER EUGENE DADY

Dr. Elmer E. Dady died September 27, 1957, at the age of seventy-two. He served as a general practitioner in Minneapolis, Minnesota, for forty-seven years. He was also a member of the staff at Deaconess Hospital in Minneapolis.

Born in Wabasha, Minnesota, Dr. Dady received his preliminary education in the public schools of that community, and his medical degree from Marquette University in Milwaukee, Wisconsin. He was a member of the Hennepin County Medical Society, and the Minnesota State Medical Association. In addition, Dr. Dady was a member of the Joppa Masonic Lodge.

His survivors include his wife, Leila; two brothers, J. F., Pomona, California, and Kenneth, Minneapolis; and three sisters, Mrs. Max Maschka and Mrs. M. Murriel Harrison, both of Minneapolis, and Mrs. Clarence W. Taylor, Bakersfield, California.

ALVIN J. KISTLER

Dr. Alvin J. Kistler, a Minneapolis physician and surgeon, died October 2, 1957. He was sixty-eight years old.

Dr. Kistler was a staff member of Swedish Hospital for more than forty years, and was a member of the Hennepin County Medical Society, Minnesota State Medical Association, American Medical Association, American College of Surgeons, International College of Surgeons, and was also on the Mount Sinai hospital staff.

Dr. Kistler was a native of Minneapolis and a mem-

ber of the Minneapolis Athletic Club and Interlachen Club. He was also a former member of the Ancker hospital staff in St. Paul. He obtained his preliminary education in Minneapolis public schools, and received his medical degree from Marquette University, Milwaukee, Wis.

Survivors include his wife, Alice; one son, Kent, Minneapolis; two sisters, Mrs. Douglas Larson, Minneapolis, and Mrs. Benjamin Greathouse, Lexington, Kentucky; and three grandchildren.

SIDNEY F. ROGERS

Dr. Sidney F. Rogers, St. Paul physician, died October 24, 1957, at the age of fifty-four.

He was a graduate of the University of Minnesota School of Medicine, class of 1932. His practice since graduation was located in the Riverview district of St. Paul.

Dr. Rogers was on the staff of Midway, Riverview and Mounds Park hospitals. In addition, he was a member of the Riverview Commercial Club, Ramsey County Medical Society, Minnesota State Medical Association, and American Medical Association.

Surviving are his wife, Gladys; two sons, Loren, with the Army in Germany, and Gary, St. Paul; one daughter, Mrs. Thomas Peterson, Rosemount; two sisters, Mrs. Clarence Bill, St. Paul, and Sister M. Dolorosa, Manakato; and two brothers, Joseph W., Costa Mesa, California and Hubert B., St. Paul.

HARRY G. WOOD

Dr. Harry G. Wood, a lung specialist at the Mayo Clinic, Rochester, died October 17, 1957, at the age of seventy-five.

He was born in Faribault, Minnesota, and graduated from Shattuck Military Academy. His medical education was obtained at McGill University, Montreal, Canada. Special work included one year of internship at Montreal General Hospital in Montreal.

Dr. Wood held the following positions and professional affiliations: association in medicine, the Mayo Clinic; assistant professor of medicine, the Mayo Foundation. He also practiced in Blooming Prairie and St. Paul.

Membership was held by Dr. Wood in the American College of Physicians, Association of Military Surgeons, American Congress of Internal Medicine, Minnesota Trudeau Society, Zumbro Valley Medical Society, Minnesota State Medical Association, American Medical Association, and Alumni Association of the Mayo Foundation. He became a member of the "Fifty Club" of the Minnesota State Medical Association in 1955.

Dr. Wood is survived by his wife, Katherine; one son, Harry G. Wood, Jr., Rochester; one daughter, Mrs. C. J. Berardini, Denver, Colorado; two grandchildren; and one sister, Mrs. A. M. Gardner, Hood River, Oregon.

MINNEAPOLIS 3, MINNESOTA

General Interest

More than 3,100 persons registered for recent mouth cancer detection tests conducted in the Willmar area. The detection team included fifteen Kandiyohi County dentists and five University of Minnesota doctor consultants. The project was sponsored jointly by the Minnesota Division of the American Cancer Society with the Minnesota State Medical Association and the Minnesota State Dental Association.

* * *

The Southern Minnesota Medical Association, at its annual meeting held September 9 at Lake City, voted to establish a student loan fund at the University of Minnesota for medical students.

* * *

Dr. Paul Giddens, president of Hamline University, has announced the appointment of Dr. Donald Roach, Roseville, as college physician. Dr. Roach received his Doctor of Medicine degree from the University of Minnesota in 1953 and has been in private practice since 1954.

* * *

Dr. Robert B. Howard has been named associate dean of the University of Minnesota Medical School to serve while University regents seek a new dean to succeed Dr. Harold S. Diehl. Dr. Diehl became senior vice-president of the American Cancer Society, New York, on November 1, but will keep the deanship on a leave basis until June. Prior to his present appointment, Dr. Howard has been associate professor of medicine and director of continuation medical education at the University of Minnesota. Dr. N. L. Gault has been assigned that job.

* * *

Dr. R. L. Erickson, is currently in the process of establishing a new practice in Rosemount. Dr. Erickson has previously practiced in Lanesboro, Minnesota, and most recently Laurel, Maryland.

* * *

Dr. Robert P. Bush, St. Paul, has been named psychiatric consultant to Family Service, a Community Chest casework agency.

* * *

Dr. Leo R. Prins has been elected new president of the Southern Minnesota Medical Association. He succeeds Dr. C. F. Stroebel, Rochester. Other officers include Dr. William O. Finkelnburg, Winona, first vice-president; Dr. C. Covell Bailey, Lake City, second vice-president; Dr. G. R. Diessner, Rochester, re-elected secretary-treasurer.

* * *

Dr. Dana W. Atchley, professor of clinical medicine, Columbia University, College of Physicians and Surgeons, was the principal speaker at the annual Minnesota Medical Foundation Day at the University of Minnesota. "The Physician As Scholar and Humanist" was the topic of his address. During the observance, 24 medical students at the University received scholarships

totaling \$12,250 from contributions of physicians, medical organizations, corporations and individuals.

* * *

Dr. Henry W. Meyerding, Rochester, president-elect of the International College of Surgeons, presided at the 22nd annual congress of surgeons of the United States and Canada held recently in Chicago.

* * *

Three Rochester surgeons were recently selected as honorary fellows of the International College of Surgeons. Included are two Mayo Foundation professors of surgery, Dr. Virgil S. Counsellor and Dr. Frederick A. Figi, and one emeritus professor of surgery, Dr. Claude F. Dixon.

* * *

Dr. Andre J. Bruwer, a specialist in diagnostic roentgenology and a member of the staff of the Mayo Clinic since 1952, has left Rochester to continue the practice of his specialty in Tucson, Arizona.

* * *

A new medical clinic is under construction in Hutchinson as a result of the joint efforts of four Hutchinson doctors. Participating in the project are Drs. Carl Bretzke, Dan Huebert, George R. Smith and Kenneth Peterson. The new clinic, a one-story brick structure, has been designed so that each physician can continue his own private medical practice, but at the same time can call upon other physicians in the clinic for assistance when necessary. Completion of the clinic for occupancy is expected for about January 1, 1958.

* * *

Dr. Henry W. Woltman, Rochester, received the University of Minnesota's outstanding achievement award recently at Minnesota Medical Foundation Day ceremonies held in the Mayo Memorial Auditorium on the Minneapolis campus, University of Minnesota. Dr. Woltman served as head of the neurology section at the Mayo Clinic and neurology professor in the Mayo Foundation, Rochester, until his recent retirement.

* * *

Dr. Robert D. Pilgrim, Benson's physician, has located in Ramona, California, where he will continue his general practice.

* * *

Post-Graduate Medicine, of which Dr. Charles W. Mayo is editor-in-chief, was one of four United States medical periodicals to be awarded the 1957 Honor awards for Distinguished Service in Medical Journalism by the American Medical Writers Association. The awards are presented annually for "accuracy, clarity, conciseness and newness of information in articles, editorials and other material, for excellence of design, printing and illustrations, and for distinguished services to the medical profession."

IN GASTRIC ULCER

PATHIBAMATE*

Meprobamate with PATHILON® Lederle

Combines Meprobamate (400 mg.) the most widely prescribed tranquilizer . . . helps control the "emotional overlay" of gastric ulcer — without fear of barbiturate loginess, hangover or habituation . . . *with PATHILON (25 mg.)* the anticholinergic noted for its extremely low toxicity and high effectiveness in the treatment of many G.I. disorders.

Dosage: 1 tablet t.i.d. at mealtime. 2 tablets at bedtime.

Supplied: Bottles of 100, 1,000.

*Trademark

® Registered Trademark for Tridihexethyl Iodide Lederle

LEDERLE LABORATORIES DIVISION, AMERICAN CYANAMID COMPANY, PEARL RIVER, NEW YORK

(Continued from Page A-52)

Dr. Bayard T. Horton, a member of the Mayo Clinic since 1929, will retire January 1, 1958.

* * *

Five new consultants and eight assistants have been named to the staff of the Mayo Clinic. The consultants are: **Drs. Leonard A. Aaro**, obstetrics and gynecology; **Robert E. Lee**, therapeutic radiology; **Emerson A. Moffitt**, anesthesiology; **John T. Shepherd**, physiology, and **William H. Weidman**, pediatrics. Assistants appointed to the staff are: **Drs. Matthew H. Bulluck**, **Allan Gould, Jr.**, **Horace Ivy**, **Charles G. Moertel**, **Paschal A. Sciarra**, **Gunnar B. Stickler**, **Welby N. Tauxe**, and **John W. Rosevear**.

* * *

Dr. C. E. Sisler, a Grand Rapids physician for thirty-five years, has accepted a position on the staff of the student health service of the University of Minnesota, Minneapolis.

* * *

Dr. R. W. Taintor has joined the staff of the Marshall Medical Center as practicing physician.

* * *

Dr. David T. Carr, consultant in medicine in the Mayo Clinic, is one of three members of a new team which will conduct research in the constant-observation unit now being constructed by the Rochester Methodist Hospital. Dr. Carr is chairman of the medical investigation unit which will direct the research in the new structure.

Dr. Leroy J. Larson, Bagley physician for thirty-two years was recently honored by 500 persons of that community. Former associates and civic leaders paid tribute to Dr. Larson at a special program held in the Bagley High School Auditorium. Dr. Larson was cited for his excellent medical service and civic leadership.

* * *

Construction of a new medical center to be known as the Professional Building has begun at 175 East Lake St. in Wayzata. Sponsors of the project are **Dr. W. W. Rieke** and **Dr. D. W. Feigal**, both of Wayzata. Also a member of this group is dentist, **Dr. Jack Anderson** of Long Lake.

* * *

Dr. J. V. Carlson, Westbrook, was recently honored for twenty-five years of service to that community.

* * *

Dr. James F. Weir, Mayo Clinic, Rochester, was elected president of the Mayo Alumni Association at the final business meeting of that group held recently in Rochester. Other new officers are: **Dr. George A. Lord**, Hanover, N. H., first vice president; **Dr. Lee Clark**, Houston, Texas, second vice president, and **Dr. Howard Andersen** of the Clinic, secretary-treasurer.

CLINICAL COLLOQUY

My patients complain that
the effect of the pain tablet I prescribe
often wears off in less than 3 hours.

*Why not try the new analgesic
that gives faster,
longer-lasting pain relief?*

You mean something that
doesn't require repeat dosage so often?

*Yes—it's called Percodan.[®]
It not only works in 5 to 15 minutes but
one tablet sustains its pain-relieving effect
for 6 hours or longer!*

How about side effects?

*No problem. For example,
the incidence of constipation
is rare with Percodan.**

Sounds worth trying—what's the average adult dose?

One tablet every 6 hours. That's all.

Where can I get literature on Percodan?

Just ask your Endo detailman or write to:

ENDO LABORATORIES

Dr. William L. Estes, Jr., of Bethlehem, Pennsylvania, president-elect of the American College of Surgeons, delivered the Judd-Plummer Memorial Lecture, "Inguinal Hernia and Its Treatment," at the recent meetings of the Alumni Association of the Mayo Foundation. Recipients of awards presented at the meetings were Dr. Irwin J. Fox for meritorious research; Dr. John C. Turner, who received the Howard K. Gay Memorial Fund, and Dr. Harry N. Hoffman, II, who received the Postgraduate Medical Travel Award.

* * *

Dr. Ralph K. Ghormley, head of the Section of Orthopedic Surgery in the Mayo Clinic from 1947 to 1955 and professor of orthopedic surgery in the Mayo Foundation, was honored at a gathering of his colleagues and former fellows in Rochester recently. A traveling education scholarship to be awarded to fellows in orthopedic surgery of the Mayo Foundation was established and named in honor of Dr. Ghormley. Dr. Ghormley is a past president of the American Orthopedic Association, the Clinical Orthopedic Society and the American Board of Orthopedic Surgery, and a consultant in orthopedic surgery to the Veterans' Administration in Washington, D. C. Dr. H. H. Young, chairman of the Sections of Orthopedic Surgery in the Mayo Clinic, was master of ceremonies for the occasion and Dr. E. W. Johnson, Consultant in Orthopedic Surgery in the Mayo Clinic, was chairman of arrangements. Speakers included Dr. Frank S. Babb, clinical instructor in surgery in the University of Minnesota Medical School and Dr. Edward H. Henderson, who described his experiences in England as an exchange graduate fellow in orthopedic surgery.

* * *

Dr. T. G. Murn has left the Mesaba Clinic in Chisholm, Minnesota, to enter practice in St. Cloud.

* * *

Former fellows and staff members of the Mayo Foundation in Rochester, Minnesota, honored Dr. William F. Braasch, urologist, recently. An oil portrait of Dr. Braasch was presented to Dr. C. W. Mayo of Mayo Clinic and Mayo Foundation. Dr. Braasch, a past president of the American Urological Association and of the Clinical Society of Genito-Urinary Surgeons, a founder of the American Board of Urology in 1934, an acting director of the Mayo Foundation and member of Mayo's Board of Governors, was retired from the Clinic in 1946. Since that time he has been consulting physician of the Olmsted Community Hospital. Dr. John L. Emmett of the Section of Urology of the Mayo Clinic, was chairman of arrangements and Dr. C. D. Creevy, head of the department of Urology of the University of Minnesota Medical School, was general chairman of the ceremonies. Among speakers were Dr. Gilbert J. Thomas, Santa Monica, California; Dr. Russell M. Wilder, emeritus member of the Mayo Clinic staff; Dr. A. Miles Griffin of Oakland, California; Dr. Charles C. Higgins of the Cleveland Clinic; Dr. William

of the Interstate Postgraduate Medical Association of North America, in Chicago, September 28 to October 3. Drs. Edward H. Rynearson, Waltman Walters, and George A. Hallenbeck of the Mayo Foundation Graduate School, Minneapolis, also participated in the program.

* * *

At a meeting of the Southwestern Minnesota Medical Society held in Worthington, September 16, Dr. Lucian Smith, department of medicine, Mayo Clinic, Rochester, was the guest speaker. His subject was "Pain Patterns and Treatment in Peptic Ulceration of the Esophagus, Stomach and Duodenum." The Society's Woman's Auxiliary, meeting at the same time, had as its speakers Mrs. C. L. Oppegaard of Crookston, president of the Woman's Auxiliary to the Minnesota State Medical Association.

* * *

Hypertension was the subject of the final meeting of the three-day Minnesota Heart Association biennial conference in Rochester recently, cosponsored by the Mayo Foundation. Dr. John F. Briggs, clinical associate professor of medicine at the University of Minnesota, and Dr. Joseph M. Janes, of the Mayo Clinic, led the case history discussions. Drs. Walter F. Kvale, William Manger and Grace M. Roth, all of the Mayo Clinic, made a joint presentation on pheochromocytoma. Drs. Manger and Roth are credited with originally working out the laboratory techniques which identify the tumor of the adrenal gland. Other speakers at the Heart Conference included Dr. Maurice Visscher, head of the Physiology Department at the University of Minnesota, and Dr. Edgar V. Allen of the Mayo Clinic and president of the American Heart Association, who talked on "Evaluation of Results of Treatment in Peripheral Vascular Disease."

* * *

Dr. Edgar V. Allen, internist of the Mayo Clinic and professor of medicine in the Mayo Foundation, presented the annual Howard W. Blakeslee Awards for excellence of presentation of popular accounts in the general field of cardiovascular diseases at a recent meeting of the executive committee of the board of directors of the American Heart Association in New York City. Dr. Allen is president of the association.

* * *

At the annual meeting of the Southern Minnesota Medical Association meeting at Lake City, September 9, Dr. R. W. Kearney, Mankato, won the medal for the best case presentation, and Dr. Mary Giffin, Rochester, was awarded the medal for the best presentation of a medical subject.

* * *

At the International Congress of Ultrasound in Medicine, held in Los Angeles, during early September, Drs. E. J. Baldes and Frank Krusen presented papers. Dr. Baldes' paper, written in association with Drs. J. F. Herrick and Charles Stroebel, was entitled "Biologic Effects of Ultrasound." The paper on "The Therapeutic Application of Ultrasound in Physical Medicine" was prepared jointly by Dr. Krusen and Dr. J. F. Lehmann, now of the University of Washington.

MINNESOTA BLUE SHIELD-BLUE CROSS

Minnesota Blue Shield payments to doctors during the first eight months of 1957 exceeded by more than \$1,000,000 the amount paid for physicians' services rendered participant subscribers during the first eight months of 1956. From January through August, 1957, subscriber benefits paid by Blue Shield amounted to \$5,689,482, a monthly average of over \$711,000. The total amount paid by Blue Shield during the first eight months in 1957 is more than 24 per cent more than the amount, \$4,579,937 paid during the same eight months in 1956 for medical-surgical-obstetrical services rendered participant subscribers.

Physicians' services for which Blue Shield paid benefits also increased more than 24 per cent during the first eight months of 1957 compared to the same period in 1956. During the first eight months of 1957, Blue Shield provided benefits for 205,143 doctors' services rendered participant subscribers, or 41,445 more than the number of doctors' services for which Blue Shield benefits were paid in the same period of 1956.

Blue Shield participant subscribers numbered 858,373 as of August 31, 1957, or 71,578 more than the number of participant subscribers enrolled as of the same date in 1956. As of this date in 1956, the number of Blue Shield participant subscribers was 786,795.

Hospital care expense incurred by 135,935 Minnesota Blue Cross participant subscribers during the first eight months of 1957 exceeded \$18,700,000, an increase of nearly \$3,300,000 over hospital care costs incurred by

121,608 participant subscribers during the same period of the previous year.

Days of care provided during the first eight months of 1957 totaled 817,238.4 days compared with 739,601.0 days of hospital care provided during the first eight months of 1956.

Analyzing all Blue Cross cases paid year to date, 1957 the leading cause of hospitalization in number of subscribers hospitalized was accident cases—22,704 cases representing 16.7 per cent of total cases paid. Dollarwise, however, hospital cases due to illnesses of the digestive system ranks first in importance—approximately \$3,300,000, or 17.7 per cent of all benefits provided. Obstetrical care ranks second in both number of hospital cases paid and amount of benefits provided—21,448 cases, or 15.8 per cent of total cases paid and over \$2,700,000 hospital care costs, or 14.8 per cent of total expense incurred.

It is interesting to note that during the first quarter of 1957, illnesses of the respiratory system outranked all other reasons for hospitalization; however, during the next five successive months the number of accidents was the leading reason for hospitalization. During the months of July and August, accident cases represented 20.1 per cent and 21.4 per cent respectively of the total cases paid.

Blue Cross membership in Minnesota totals 1,128,639 persons as of August 31, 1957, an increase of 60,657 participant subscribers or 5.4 per cent since August 31, 1956.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

TUBERCULOSIS: EVERY PHYSICIAN'S PROBLEM. J. Arthur Myers, M.D., Professor of Internal Medicine and Public Health, Medical and Graduate Schools, University of Minnesota, Minneapolis, Minnesota. 290 pages. Illus. Price \$7.50, cloth. Springfield, Illinois: Charles C Thomas, 1957.

PERATIVE OBSTETRICS. R. Gordon Douglas, M.D., Professor of Obstetrics and Gynecology, Cornell University Medical College; Obstetrician and Gynecologist-in-Chief, the New York Hospital; Director of the New York Lying-in-Hospital; and William B. Stromme, M.D., Attending Obstetrician and Gynecologist, Northwestern Hospital and Fairview Hospital, Minneapolis; formerly Instructor in Obstetrics and Gynecology, Cornell University Medical College; Assistant Attending Obstetrician and Gynecologist, the New York Hospital. 735 pages. Illus. Price \$20.00, cloth. New York: Appleton-Century-Crofts, Inc., 1957.

PRACTICAL GYNECOLOGY. Walter J. Reich, M.D., F.A.C.S., F.I.C.S., and Mitchell J. Nechtow, M.D., F.A.C.S., F.I.C.S. Ed. 2. 648 pages. Illus. Price. \$12.50. Philadelphia: J. B. Lippincott Co., 1957.

Practical Gynecology was written principally for use by the general practitioner in the office practice of gynecology. The book fills this role; the term "practical" in the title is well carried out throughout the text. The discussion is somewhat informal, and the authors have drawn on their long experience to quote illustrative cases.

The second edition has been revised to consider new concepts and current practices in gynecology. New chapters have been added to cover Pediatric Gynecology, Radiation Therapy, Geriatric Gynecology, and the Male Role in Gynecology. A useful chapter on Psychosomatics of Gynecology is included.

Treatment is discussed from a practical standpoint, utilizing the methods the authors have found best in practice. Consideration of alternative methods is quite limited. The book will be of use to the general practitioner without specialized training in Gynecology. It will be especially valuable to the younger physicians in their early years of practice.

Suppression and Absence of Enzyme Activity
as a Cause of Disease

VICTOR A. NAJJAR, M.D.
Baltimore, Maryland

IN ALL probability, most if not all diseases associated with disorders of metabolism, showing a definite or possible genetic background, are due to the absence or suppression of at least one enzyme system.

The essential lesion may be due to a complete absence of an enzyme with a consequent lack of the special function ordinarily ascribed to that particular enzyme. It can also be due to the presence of an incomplete enzyme protein that lacks activity for one or more reasons. The latter has not been looked for in mammalian disease. It has been encountered in mutants of neurospora.¹

The absence of function resulting from the lack of a certain enzyme activity may have serious consequences to the fertilized egg, the growing embryo or to the well developed fetus, as the case may be, depending on what level of development a particular enzyme is ordinarily formed. Under the circumstances, a viable fetus cannot result. On the other hand, if the enzyme is not of the type that is absolutely essential for the development of the organism or for the maintenance of life, then a child is born with some metabolic defect. This defect may not cause demonstrable disease, as in essential glucosuria pentosuria, and fructosuria or it may well do so, as in galactosuria (galactosemia), glycogen storage disease, phenylketonuria, et cetera.

In such instances, the cause of the disease may fall into one of three categories:

- 1. It may simply be a direct result of the absence of the enzyme in question.
- 2. It may be only due to the toxic products that accumulate consequent to the absence of that enzyme. In this instance, the enzyme is deemed nonessential in that it does not play a role in major pathways of metabolism or in the activation of essential metabolites.
- 3. There can also be a combination of both factors. Here the enzyme, though not essential for life nevertheless, is essential for some major pathway of metabolism and the products that accumulate, as a result of its absence, are toxic to the organism.

There are examples in pediatrics, I believe, that fall within the scope of all three of these categories and it is this type of metabolic disorder which is the subject of this discussion.

Metabolic Diseases with Manifestations Directly
Attributable to the Absence of Enzymes

The most classical example of this type of disease is the type of glycogen storage disease in which there is absence of a specific glucose 6-phosphatase.²⁻⁵ Here the whole symptomatology of the disease can readily be deduced from this simple fact.⁶⁻⁷ One should, however, be acquainted with the function of this enzyme in relation to the steps involved in the enzyme in relation to phosphorylation into glucose 6-phosphate and its conversion to glycogen or lactic acid. In the liver, the main events governing the fate of blood glucose are as follows:

Third Irvine McQuarrie Lecture given under the sponsorship of the Department of Pediatrics, University of Minnesota, September 25, 1957.
From the Department of Pediatrics, Johns Hopkins University School of Medicine and Harriet Lane Home, Johns Hopkins Hospital, Baltimore, Maryland.
At the time this lecture was prepared, Dr. Najjar was Associate Professor at Johns Hopkins University School of Medicine. His present address is Department of Microbiology, Vanderbilt University, School of Medicine, Nashville, Tennessee.

Blood glucose is taken up by liver cells, and converted to glucose 6-phosphate by hexokinase, using the terminal phosphate of ATP (adenosinetriphosphate). This glucose 6-phosphate can be converted to glycogen or to lactic acid through a series of steps that we need not develop here. When blood glucose is high, as after a meal, most of the glucose that enters liver cells is stored as glycogen. There is a purpose in this particular function of the liver in that the stored glycogen can then be mobilized into blood glucose again. This occurs when there is a general need for glucose by other tissues. The organ that is constantly in need of blood glucose is the brain. Other tissues, unlike brain tissue, have a good reserve of glycogen stores. The maintenance of a normal blood glucose level however, remains the sole responsibility of the liver. No other tissue can substitute for this liver function. To do this, the liver has the specific glucose 6-phosphatase that hydrolyses glucose 6-phosphate to release free glucose into the blood stream. Muscle tissue with its total large stores of glycogen possesses no such enzyme and cannot therefore, furnish any substantial amount of glucose to the blood. In response to a glucose need, liver glycogen breaks down to glucose 6-phosphate which in turn is acted upon by the specific phosphatase to replenish blood glucose. In the liver the enzyme is present only in the cytoplasm of hepatic cells. In the kidney it is localized only in the proximal convoluted tubules and the glomerular endothelium.

In the absence of this enzyme, this function is erased from the physiologic pattern of balance and homeostasis. The overall picture, in simple terms, resolves itself into an ability to store glycogen from blood glucose but an inability to transform glycogen to blood glucose. Glycogen can only break down to lactic acid; a requirement that is only minute compared to the requirement for blood glucose.

A patient lacking this enzyme would, by reason of this one difficulty, develop all the manifestations associated with the classical von Gierke's disease. There is accumulation of glycogen in liver cells, much above the normal range. The individual cells appear large and engorged with glycogen. The whole liver becomes enlarged as a result. Blood glucose values drop to subnormal levels between meals. This is particularly pronounced during the overnight fast. Ketone bodies

appear in the urine, a result of incomplete oxidation of fatty acids.^{4,5} Adrenaline which stimulates the breakdown of glycogen through the phosphorylase system, cannot effect the normal rise in blood glucose because that pathway is blocked by the absence of the enzyme. Furthermore, the patient would seem to be in a continuous state of glucose starvation, a state which can readily explain the prolonged starvation type of glucose tolerance curve obtained in these patients.

Since this type of patient suffers only because of the attending hypoglycemia, it is to be expected that most if not all manifestations can be alleviated by correcting the hypoglycemia. This is done by frequent feedings along with a high protein diet. This has proved highly effective in one such individual⁸ who subsequently showed complete recovery.⁶ The recovery coincided with the onset of puberty.

It should be pointed out here that this type of glycogen storage produces no abnormality in the structure of glycogen by contrast to other types. The abnormality of the glucose 6-phosphatase is the only one observed and involves both liver and kidney tissue. There is a second and very similar type of glycogen storage disease in which the glycogen is also normal and the specific phosphatase is unimpaired. Glycogen storage here is generalized in all tissues, especially in the cardiac and skeletal muscles. The latter type is to be distinguished from a third and a fourth type where the glycogen is of abnormal structure. In one instance the glycogen is much more highly branched and in the other it is much less branched than normal glycogen. The specific glucose 6-phosphatase, in each of the latter types, is normal. The deficiency lies in the brancher or the debrancher enzymes.^{3,10} This will be discussed under the appropriate section below.

Another illustration of a disease caused by the absence of enzymes is the commonly encountered fibrocystic disease (mucoviscidosis). The precipitating cause is not known, yet the fibrotic changes in the pancreas that occur in the antenatal and postnatal periods result in deficiency if not total absence of the pancreatic enzymes. This disease is no less representative of this class than glycogen storage disease. It does lack a certain measure of glamor because it is not a clean-cut absence of one single enzyme. Nevertheless, it represents in every respect a disease in which most manifesta-

tions can be deduced from the knowledge of the function of the enzymes involved.

Meconium ileus is caused by the failure to liquefy the thick mucilagenous meconium plugs, due to the absence of the pancreatic enzymes.¹¹ The loss of proteins through the stools, because of the lack of proteolytic digestion, results in poor growth and poor musculature. The poor absorption of fat, and carbohydrates also due to the lack of splitting, because of the absence of the lipase and amylase enzymes, results in a chronic state of semistarvation.¹² As a direct result of this, one finds the large ravenous appetite. Fat soluble vitamins remain held in the fatty stools and little is absorbed. Vitamin deficiencies of the A and D types result whether outwardly manifested or not. Fatty stools also hold a lot of calcium as insoluble soaps. The loss of calcium absorption is responsible for osteoporosis.

The major manifestations of the disease are undoubtedly due to the pancreatic lesion, although this is much aggravated by other anomalies¹³ such as the sweat glands¹⁴ tracheobronchial glands, salivary glands and the mucous glands of some parts of the gastrointestinal tract.¹³

Metabolic Diseases with Manifestations Attributable Only to Toxicity of Substances that Accumulate as a Consequence of the

Absence of Enzymes

Good examples of this category have come to light only recently. I shall discuss two such instances.

Galactosemia (galactosuria) is a metabolic disease in which there is little or no utilization of galactose. Its principal manifestations are catarract formation, brain damage and cirrhosis of the liver with jaundice and splenomegaly. Patients with this disease have been known to improve dramatically when placed on a galactose free diet.¹⁵ Indeed, a good many of them are now adults showing normal, physical and mental development. It is not known whether in the course of growth to adulthood they may acquire some measure of resistance to the toxic effect of galactose. What is known with certainty is that galactose is decidedly toxic to young infants and children. It is also toxic to newborn animals¹⁶ and is one of the potent causes of neonatal jaundice, a fact that is not commonly appreciated.^{17,18} There is hardly any utilization of galactose in

such patients and this may only amount to 1 to 3 per cent.¹⁹ Galactose accumulates in the blood and is excreted in the urine. Recently, it was shown that in addition to this there is also an accumulation of galactose 1-phosphate in the red blood cells of these patients.²⁰ This indicates that galactose metabolism was inhibited beyond this stage.

It has been known that galactose metabolism is dependent on three enzymatic steps. The first is phosphorylation of galactose to galactose 1-phosphate.²¹ This enzyme, termed galactokinase, is apparently normal in these patients. The second is incorporation of galactose 1-phosphate into a uridine nucleotide containing glucose 1-phosphate. The galactose merely replaces the glucose in this nucleotide according to the reaction: Uridinediphosphoglucose + galactose 1-phosphate to yield uridinediphosphogalactose and glucose 1-phosphate.²² The enzyme is called uridyl transferase.²³ The third step is the conversion of uridinediphosphogalactose into uridinediphosphoglucose.²² This reaction was described as the waldenase reaction and recently has been more properly renamed epimerase.²⁴

It has been shown lately that it is the transferase that is defective in galactosemia. The red cells and livers of these patients show practically complete absence of this enzyme.^{19,23} The epimerase is present in normal concentrations.

The fact that patients do very well when galactose is withheld from the diet, indicates clearly that the absence of the transferase enzyme *per se*, does not impair the metabolic function of the tissues in these patients. Further, the observation that symptoms of galactosemia appear only when galactose is ingested, point clearly to a toxic effect by galactose or any of its accumulated products. We have already indicated above that galactose 1-phosphate does indeed accumulate in red cells to a considerable extent.^{20,23} The toxic effect must reside in one or both of the accumulated products. A toxic compound can be toxic only by virtue of the fact that it can interfere in some enzymatic step in metabolism. It was not thought likely that free galactose would so interfere, for a number of reasons that are not within the scope of this discussion. It was felt that, inasmuch as galactose does not inhibit respiration of red cells from normal individuals, but in fact enhances oxygen uptake, then it could not be responsible for any toxic effects.²⁰ The notion that galactose

1-phosphate accumulation might have an unfavorable effect on tissue metabolism was then entertained. It was strongly suggested by the work on the mechanism of action of phosphoglucomutase, which has engaged our attention for the past few years.^{25,26,27} This enzyme converts glucose 1-phosphate to glucose 6-phosphate. It does so in the first step by transferring, from its active surface, its only phosphate group to carbon 6 of glucose 1-phosphate, to yield glucose 1,6-diphosphate. In the next step, the enzyme that has already lost its phosphate to carbon 6, proceeds to replace that loss by detaching the phosphate from carbon 1 of glucose 1,6-diphosphate, to yield glucose 6-phosphate. At the same time, it recovers the phosphate to its active site and is ready for another run of activity. It is worth repeating that it is essential for the enzyme to recover the lost phosphate in order to react with glucose 1-phosphate to produce glucose 6-phosphate.

It has recently been shown that galactose 1-phosphate is converted to galactose 6-phosphate by the same enzyme phosphoglucomutase. However, this occurs at a much slower rate, amounting to 1/400th of that of glucose 1-phosphate transformation.²⁸ On the assumption that this conversion follows the same pattern, it was predicted that galactose 1-phosphate would be a strong inhibitor of this enzyme by virtue of the slowness of its conversion. This would indicate that in the presence of both hexose phosphates, a good many of the enzyme molecules would, at any one time, be without a phosphate group on their active surfaces. The phosphate that the enzyme donates to carbon 6 of galactose 1-phosphate is not readily recoverable from carbon 1 of galactose 1,6-diphosphate because of the slowness of this reaction. In essence, then, galactose 1-phosphate acts as a trapping agent for the phosphate of the enzyme. As we indicated above, the dephosphorylated enzyme is inactive towards glucose 1-phosphate, its normal substrate.

Using rabbit enzyme, it was possible to show that about one hundredth of the concentration of galactose 1-phosphate obtained in the red cells of galactosemic patients, sufficed to inhibit the activity of phosphoglucomutase about 80 per cent when tested *in vitro*.²⁹ This is a high degree of inhibition when it is recalled that this enzyme plays an important role in carbohydrate, nucleic acid and mucopolysaccharide synthesis. This magnitude of inhibition can well explain the toxicity

of galactose 1-phosphate to the brain, producing mental deficiency; to the liver, resulting in cirrhosis and jaundice; to lens tissue, producing cataract; to kidney tissue, producing albuminuria and aminoaciduria; and to the body metabolism as a whole resulting, in slowness of growth.

Galactosemia then represents a perfect example of this disease entity where there is an absence or deficiency of the uridyl transferase enzyme. Such a defect in itself, is not detrimental to the well-being of the individual involved. The danger lies in the ingestion of galactose compounds which result in a considerable accumulation of galactose 1-phosphate in tissue cells. This produces an inhibition of phosphoglucomutase activity by the simple incorporation of galactose 1-phosphate into the mechanism of the enzymatic reaction to trap the essential active phosphate group of the enzyme. I dare say that this makes galactosemia one of the best understood diseases in pediatrics.

Another disease has been described during the past few years that may well fit into this category. It is *congenital familial nonhemolytic jaundice with kernicterus*.³⁰ In this disease, there accumulates in the serum of patients the direct type of bilirubin.^{31,32} The disease has a very definite genetic background.³³ It was suggested, from load experiments, that the liver in such patients, is incapable of excreting bilirubin at an adequate rate when the bile pigment is at normal serum levels.³⁰ Because the accumulated bilirubin was found to be of the indirect type, it was further suggested that more precise defect would most likely be an inability of the liver to convert indirect to direct bilirubin.³³ This was based on a similar type of reasoning advanced earlier to explain jaundice in the premature³⁴ and the occurrence of hyperbilirubinemia in a strain of rats with hereditary congenital jaundice.³⁵

The patients so afflicted mostly died in early infancy with clear-cut evidence of kernicterus. There was no definite pathologic findings noted in any organ with the exception of bilirubinemia. All these children appeared normal at birth. Jaundice appeared rapidly and was maintained at a high level of severity throughout the period of observation. In most patients no evidence of kernicterus appeared during the first few weeks of life and in one instance, did not become evident until two to three months of age. There were two children who never developed any central

nervous system manifestations and are still alive. One is seven (J. D. H.) and the other (M. E. H.) is four years old. They are both in perfect health except for the ever-persistent jaundice of about 20 mg. per cent of indirect bilirubin. The prognosis in these two cases nevertheless, should remain guarded particularly in the light of a recent report of one similar case developing kernicterus at the age of three years.³⁶

It has been shown lately that bilirubin obtained from bile is in the form of a glucuronide conjugate.^{37,38} The linkage occurring at the propionic acid groups.^{37,39,40,41} Studies of this enzymatic step in animals showed that newborn and fetal livers virtually lacked the ability to conjugate bilirubin, whereas adult animal livers contained an active enzyme.⁴² It then appears that this enzyme develops to a large extent after birth, at least in the guinea pig. The observations with newborn infants³⁴ seem to indicate also that the enzyme is poorly developed in the human liver at birth. However, it develops rapidly shortly after birth. This indeed would be enough to explain the occurrence of physiologic jaundice and its disappearance that coincides with the full development of this enzyme system. This might be true only if the mechanism of transport and excretion of bilirubin is dependent on this enzyme.

Should this enzyme fail to develop it would result in accumulation of indirect bilirubin in the serum of newborns. A clinical picture would then result similar to that obtained in the cases discussed above. If the accumulated bilirubin is toxic to tissues at a particular stage of their neonatal development, then manifestations of toxicity would develop. It may well be that kernicterus is produced in this manner, considering the fact that bilirubinemia is the common denominator in practically all cases showing kernicterus. These include blood group incompatibility, hemolytic disease of the new born, jaundice in the premature, overdosage with vitamin K or its analogues in the early newborn period et cetera, as well as the cases referred to above.⁴³ Studies on the two surviving cases indicated a considerable reduction in the glucuronide conjugating system using salicylate and compound F as glucuronide acceptors.⁴⁴ The possibility that bilirubin is actually toxic is supported by *in vitro* studies which showed an inhibitory effect on brain respiration.

The fact that the two surviving cases with

bilirubinemia still appear for all practical purposes, in good physical condition, showing normal growth and development, suggests that this familial and inherited disease, like many other heritable diseases, expresses itself with different levels of severity. It is interesting that in the first series of seven cases reported,³⁰ the only survivor (J.D. H.) showed serum bilirubin levels well below three of the five cases studied and who died with kernicterus. Proceeding on the premise that the damage done, results from the accumulation of the indirect bilirubin in serum, this disease then clearly fits into this category of heritable disorders of metabolism. This defect in itself is presumed not to be detrimental to the health of the individual until the metabolite concerned (free bilirubin) reaches a certain toxic level in the serum. In fact a similar defect is described in adults, and referred to as *familial non-hemolytic jaundice*. It is basically a defect in the excretion of bilirubin and presumably involving the same enzyme system. Here bilirubin also accumulates in the serum, but to levels far lower than those observed in the entity described above. No kernicterus develops nor any other manifestation of damage to any organ.⁴⁵

In all respects then this disease resembles galactosemia where the accumulation of galactose to high level causes the damage and not the enzyme deficiency *per se*.

Metabolic Diseases with Manifestations Attributable Both to the Absence of Enzymes and to the Toxic Products that Accumulate Therefrom

Again metabolic diseases that fall in this category have been defined only recently.^{2,3,10}

Glycogen storage disease, as brought out earlier in this discussion, is classified into four types. One shows only a deficiency in glucose 6-phosphatase. Another shows no such defect and the glycogen structure is normal. The other two types represent instances where the glycogen structure is abnormal. The glycogen molecule may be more branched or less branched than it is normally. The last two types belong to this category.

It is necessary at this point to describe briefly the formation of normal glycogen. Suffice it to say that glycogen is a branched polysaccharide composed of glucose residues. One glucose unit is linked to another mostly by a carbon 1 to

carbon 4 linkage. This straight chain type of linkage is formed or broken by the reversible action of the enzyme phosphorylase. There have been no instances to date that revealed a defect in this enzyme. At the branch points, another type of linkage exists. Carbon 1 of one glucose unit is linked to carbon 6 of another. In this linkage two enzymes participate. The brancher (transglucosidase) forms this linkage and the debrancher (glucosidase) breaks it. Thus, for the synthesis of the tree-like glycogen structure, phosphorylase and the brancher co-operate. For its breakdown phosphorylase and the debrancher work together.

It would be easy to see that a defect involving the brancher results in the synthesis of a polysaccharide with few branches. In that respect it would resemble starch. On the other hand, should the debrancher be deficient, the polysaccharide formed would be highly branched, inasmuch as, the brancher enzyme remains unopposed for lack of debrancher activity.

It appears that both of these abnormal glycogens do not break down readily and therefore accumulate in the affected organs. The liver is involved in both types. Muscle involvement is more commonly seen in the type where the debrancher is deficient. It has also been supposed that these abnormal glycogens stimulate fibrosis and result in destructive changes in the musculature and cirrhosis of the liver. In this manner glycogen behaves as a foreign body.

The metabolic disturbances in such cases, though present, are not as severe as those observed in the type where glucose 6-phosphatase is deficient. The main manifestations are secondary to mechanical and fibrotic alterations. This gives rise to symptoms of cirrhosis in the liver with splenomegaly, hypoproteinemia, anemia, compensatory venous dilatation and ascites. In muscle tissue the symptoms are muscle weakness, sometimes resembling amyotonia and also cardiac failure.^{6,7,46}

It is clear then that the absence of these enzymes in each instance is detrimental to the organism in that glycogen is stored in large quantities and is not readily available to the particular tissue for metabolic purposes. The secondary effects of the accumulated glycogen is even more detrimental and indeed responsible for the fatal outcome.

Another disease entity that falls within this

group is *phenylketonuria*, more generally known as phenylpyruvic oligophrenia.

The fundamental anomaly in this disease has lately been clarified. In essence, it is an inability to convert phenylalanine to tyrosine. This hydroxylation reaction, catalyzed by hydroxylase, occurs in the liver and involves two components.⁴⁷ Fraction I is unstable and is present only in liver tissue. Fraction II is stable and is found in all tissues. Recent reports indicate that fraction I is lacking or deficient in the livers of these patients.^{48,49}

The inability to hydroxylate phenylalanine explains most of the chemical manifestations of the disease. These include an accumulation of phenylalanine in the blood and spinal fluid, the appearance of phenylpyruvic acid, phenyllactic and phenylacetic in the urine.^{50,51} The symptomatology of the disease includes in the main, mental deficiency, blonde hair and blue eyes, eczema and convulsions. It is true that symptoms may appear very early in infancy, yet it is difficult to evaluate many of the specific diagnostic criteria in the newborn or in the early postnatal period. Retardation, mental and physical, should however, be apparent well before the age of six months. Chemical tests of course, would be meaningful at any age. The variability in the manifestations of this disease however, should be very carefully considered in assessing the developmental state of the patient.⁵²

It is entirely possible that the newborn child may be normal and that damage ensues later on when phenylalanine accumulates in the blood. However, the reason for including phenylketonuria in this category, rests on a belief that the fetus in utero is likely to suffer damage because of the absence of the hydroxylase. Otherwise, this disease entity would have been placed in the same category with galactosemia. It may well be that further studies may so indicate.

Numerous observations point to the fact that phenylalanine, or one of its metabolites, may indeed be toxic.⁵³ Phenylacetic acid is excreted as a glutamine conjugate. Its excretion in this form is particularly high in severely defective patients.⁵³ One wonders whether the drain of glutamine may not be responsible for some of the manifestations of this disease, particularly that glutamine is concerned with ammonia fixation in the brain. Patients with this disease maintained on diets low in

phenylalanine showed striking improvements in their symptoms. It was noted that convulsions stopped with a disappearance of abnormal electroencephalographic patterns. There was a measurable improvement in the physical and mental development of the child. Following the reintroduction of normal dietary levels of phenylalanine, a reversion to the original status was observed in most symptoms of all cases observed.⁵¹⁻⁵³

It is obviously important to start the therapeutic diet as early in life as possible. It is only then that one can ascertain whether any prenatal damage had occurred. Judging by the encouraging reports to date, it may well be that keeping the phenylalanine intake at a minimum, will result in normal growth and development. In that case a patient with phenylketonuria could then enjoy the status so far accorded the galactosemic child, who now can grow and develop unmolested by the grave and potential threat that lies within.

Acknowledgments

The investigations referred to in this paper that were carried out by the author or his associates (Ref. 29, 44) were supported in part by research grant No. RG-3209 from the Division of Research Grants, National Institutes of Health, United States Public Health Services, Bethesda, Maryland.

STRESS VS. HEART DISEASE

Socioeconomic stress "peculiar to and characteristic of the middle and upper class male of western society" rather than dietary fat intake is suggested as a possible cause for the high incidence of coronary artery disease by two California investigators.

Drs. Meyer Friedman and Ray H. Rosenman of the Harold Brunn Institute, Mount Zion Hospital, San Francisco, conducted a detailed dietary survey of forty-six women and their husbands belonging to an upper economic stratum. The caloric and percentage of fat intakes of the two sexes was found to be almost identical.

From a critical review of various data relating to a known relative immunity of the American woman to clinical coronary disease, the authors conclude that this immunity cannot be due entirely to some endoc-

rine-induced protection against the supposed atherogenic properties of a high-fat diet. Protection against this disease does not appear to be a sex-linked phenomenon in all races; also, this relative immunity dwindles with hypertension and disappears with diabetes.

The authors point out that the fat intake of several races is comparable to that of the middle-class or upper-class American, yet their incidence of coronary artery disease is almost nonexistent. In most epidemiologic studies, "little attention has been paid to the really striking fact that immune groups invariably have belonged to either the lower socioeconomic class of western society or to groups not belonging to this society. Conversely, only middle and upper class western man has this disease in abundance."—FRIEDMAN, M., and ROSENMAN, R. H.: Comparison of fat intake of American men and women. *Circulation*, 16:339 (Sept.) 1957.

Infantile Cortical Hyperostosis

Report of a Case in an American Indian

GEORGE S. BOYER, M.D.
Crookston, Minnesota

WEST¹ and others in 1888 published reports concerning acute periosteal swellings in infants, but there were no roentgenograms to prove the diagnosis since x-rays had not yet been discovered. Roske,² in 1930, first described an unusual bone condition in an infant which he

Thoman and Murphy⁹ in 1950 reported the first and this is believed to be the second case occurring in an American Indian.

Classically infantile cortical hyperostosis occurs from the last month *in utero*^{10,11,13} to the first six months of life.¹² It has been found in siblings¹¹

Fig. 1. (A) Right mandibular cortical hyperostosis in lateral oblique projection at four months of age. Condyles are not affected. The body and rami are thickened. (B) Same mandible at eight months of age, showing complete regression of lesion.

believed to be a new disease entity. It was dramatized by Caffey and Silverman³ in 1945, Caffey⁴ in 1946, and Smythe, Potter, and Silverman⁵ in 1946, who gave complete clinical and roentgenographic reports of this syndrome and named it infantile cortical hyperostosis. Caffey⁴ in 1938, 1939, 1940, and 1944 had seen four cases of cortical hyperostosis in infants which were not due to luetic infections. Ross and Burke⁶ suggested the name Caffey-Smythe syndrome. Walley⁷ in 1953 chronologically arranged the first forty-three reported cases of this disease. In 1954, Sidbury⁸ reported that there were over sixty cases in the literature. More than a dozen cases have been reported since then.

Infantile cortical hyperostosis has been reported in all ethnic groups throughout the world.

From St. Francis Hospital and The Northwestern Clinic, Crookston, Minnesota.

and in the second generation.¹⁰ Bennett and Nelson¹³ reported the first prenatal case in 1953. The duration of the disease is variable with frequent remissions and exacerbations. One area of bone may heal while another area becomes involved. New lesions are rare after the first year of life and the entire course of the disease may be only three months. Lesions can heal and recur in the same site. Rib lesions show the most rapid healing. The average age at onset in the first sixty-nine cases reported was nine weeks.

This disease usually runs a benign course, but Caffey¹⁴ described some late chronic changes in a few cases resulting in crippling residuals. In most cases there is a sudden onset of swelling of the face, jaw, extremities or thorax accompanied by fever, hyperirritability, periods of remission and exacerbation and roentgenographic evidence of diaphyseal subperiosteal new bone forma-

tion. Most bones have been involved except the metacarpals. The mandible and clavicle are most commonly involved. Multiple osseous

changes,^{4,5,18,19,22} but Kane and Borzell²³ and Larkin and Rousseau²⁴ found inflammatory infiltration with periosteal hyperplasia. Smythe⁵ re-

Fig. 2. (*above*) (A) film of portion of left upper chest at four months of age, showing severe cortical hyperostosis of left clavicle, the ribs, and minimal changes in the scapula. (B) Same area at eight months of age, showing minimal changes in the clavicle but almost complete regression in the ribs.

Fig. 3. (*below*) Right elbow at four months of age, showing moderate to severe cortical hyperostosis of humerus, ulna and radius. Lamination of the calcium deposits is seen. (B) At eight months of age, the humerus has cleared, but a pathologic condition persists in the forearm.

involvement is usual, but Coley¹⁵ described four cases of monostotic disease which were first considered primary malignant tumor. Etiology is unknown, although many theories have been advanced.^{4-6,8,11,16-21} Few biopsies have been done. Most of those done show noninflammatory

ports muscle and connective tissue changes. Autopsy reports, although few in number, have been normal except Mossberger's patient, who probably died of typhoid fever.¹⁸ Diagnosis is suspected clinically by brawny tender swelling of the jaw or limbs, fever, anemia, leukocytosis, and irri-

tability. Roentgen study confirms the diagnosis. Where the mandible only is involved diagnosis is more difficult.

No tuberculosis or syphilis was present in either parent.

Physical examination revealed the forearms to be thickened and to have a very woody feeling. Clavicles,

Fig. 4. (*above*) (A) Massive cortical hyperostosis in left femur at four months of age. Both femorae are equally affected. (B) Right femur four months later, showing considerable cortical hyperostosis remaining.

Fig. 5. (*below*) (A) Massive hyperostosis of left tibia and fibula with laminar deposition at age four months. (B) At eight months, there has been complete regression.

Case Report

E. S., a Chippewa Indian boy four months of age, was admitted on September 1, 1955, to St. Francis Hospital from the Red Lake Indian Reservation because his mother said "There was something wrong with his arms and shoulders." Two other siblings, three years and eighteen month old, were healthy. Birth weight was thirteen pounds and thirteen ounces.

arms, and legs were tender. One could not pick up subcutaneous tissues between the fingers. Similar hard lumpy masses were present over the thighs and clavicles. The mandible was not swollen. Laboratory studies showed normal urine. Serologies of the patient and his mother were negative. Blood studies showed hemoglobin 10.25 gm. per 100 cc.; red blood cells 4,890,000 per c.mm.; white blood cells 14,000 per c.mm.; differen-

tial white count was normal. Electrocardiogram was normal. Serum alkaline phosphatase was 37.5 King and Armstrong units. Serum calcium was 4.9 milliequivalents per liter or 9.8 milligrams per 100 cc.

Roentgenographic studies (Figs. 1-5) showed extensive internal cortical atrophy, some marrow cavity expansion, and external swelling of the shafts of the ulnae, radii, humeri, fibulae and tibiae. Only the diaphysis of these long bones was involved. The epiphysis and metaphysis were spared. Severe subperiosteal cortical hyperostosis was most marked in the thighs, forearms, clavicles, and ribs. The mandible was involved on both sides but most marked on the right side. The jaws were not swollen. Cortical overgrowth also involved the scapulae to a moderate degree. Skull, vertebrae, carpal, and metacarpal, tarsal, metatarsal, pelvis, and phalanges of the hands and feet were not involved. Roentgen examination of the chest and barium study of the esophagus and stomach revealed a normal condition.

During the initial two-week hospital stay, this child had a temperature of 99-102° F., reaching normal values upon hospital discharge. Bottle feeding was difficult, and the child cried whenever the arms, legs or chest were touched. Pabulum formula was rejected, and the child refused to chew.

Differential diagnosis of luetic periostitis, scurvy, rickets and vitamin A intoxication were excluded by the roentgen picture of diaphyseal involvement only, negative serology, history of previous vitamin intake, laboratory studies, and the typical clinical findings of anemia, fever, irritability and response to supportive therapy.

On January 25, 1956, nearly five months later, this infant was seen in the clinic for re-examination and roentgen study. Weight was now sixteen pounds, nine ounces, ribs were prominent, arms and legs were not as lumpy or woody feeling as before. The child sat up and tried to crawl. Roentgen examination shows complete healing of the mandible, scapulae, most of the ribs, tibiae, fibulae, humeri and residual cortical hyperostosis of the femorae, radii, ulnae, clavicles, and several of the ribs. Clinical improvement had been excellent. Correspondence with the physicians at the Red Lake Indian Reservation Hospital since then relate continued improvement to normal. Roentgen studies done April 1, 1957, at the Indian Reservation by Drs. Lane, Ghrist, and Kidd show complete recovery of all involved bones to normal with no residuals.

Comment

The benign course of this disease and the excellent prognosis is well known. Rapid recovery was evident on re-examination nearly five months later. One year later no residuals to palpation were present. Nineteen months later all involved bones were normal following roentgen study.

The treatment of this child was supportive. There appeared to be no proven method of care in the literature.²⁵ Brailsford¹⁶ advocates ascorbic acid, Sidbury⁸ and Pounders and Delhot²⁶ re-

port excellent results with cortisone and hydrocortisone. Bowman, Cosby, and Piston²⁰ reported two cases which improved after milk was removed from the diet. de Córdova and Pessino,²⁷ however, had poor results using hormones.

Although extensive bone disease is present, these infants continue to grow and develop normally. It is not a rare entity and should be suspected in any infant with anemia, leukocytosis, hyperirritability, fever, and swelling of jaws or limbs. Brooksaler and Miller²⁸ reported eleven cases in six years.

Summary

A brief review of the history, clinical picture, laboratory findings, roentgen findings, etiology, prognosis and therapy of infantile cortical hyperostosis has been given. Another case in an American Indian infant is presented. The diagnosis can be suspected clinically and is proven by complete body roentgen study.

Pilot Study of Effects of Stimulant Drugs on Regressed Patients

M. DUANE SOMMERNESS, M.D.
RUBEL J. LUCERO, M.A.
Fergus Falls, Minnesota

RECENT literature has been crowded with reports of the effects of tranquilizing drugs on the overactive, disturbed patient. Relatively little research has been done on the chemothera-

peutic approach to the equally large problem of the regressed patients that crowd mental hospitals. The authors hypothesized that, if tranquilizing drugs calm the overactive patient, stimulating

GRAPH 1. PLACEBO GROUP.

Dr. Sommerness, formerly on the staff at Fergus Falls State Hospital, Fergus Falls, Minnesota, is now Superintendent at Traverse City State Hospital, Traverse City, Michigan. Mr. Lucero, formerly at Fergus Falls, is now a senior clinical psychologist at Willmar State Hospital, Willmar, Minnesota.

drugs might cause the regressed patient to become more alert and responsive to his surroundings and thus acquire a higher level of social adjustment. The authors decided to carry out a small

pilot study to determine whether there would be reason to run a full scale research project to test this hypothesis.

day. The experiment continued for fourteen days. The dosage was cut in half on the fifteenth day and discontinued on the sixteenth day. The in-

GRAPH 2. RITALIN GROUP.

Procedure

Twelve of the most regressed men patients in the 1800-bed Fergus Falls State Hospital were selected for this study. The patients were placed in three groups: one group to receive placebo; another, Ritalin (methyl-phenidylacetate hydrochloride, Ciba); and the third group, Wyamine (mephentermine sulfate, Wyeth). Behavior ratings^{1,2} were done immediately before and after the experiment to determine if there was improvement in the overt social behavior of the patients. Blood pressures were taken every day of the experiment as a clinical safeguard to the patients because of the effect stimulating drugs might have on blood pressure. Red and white blood counts and hemoglobins were determined pre- and post-experimentally. The experimenters met with ward personnel and patients once daily to observe the patients and determine the dosage for the next

TABLE I. BLOOD STUDIES

Hemoglobin Per Cent			
	Pre	Post	Difference
Placebo	95.75	89.50	-6.25
Ritalin	93.00	89.25	-3.75
Wyamine	88.50	88.75	+ .25

Red Blood Count			
	Pre	Post	Difference
Placebo	5,265,000	5,322,500	+ 57,500
Ritalin	5,122,500	5,150,000	+ 27,500
Wyamine	5,320,000	5,085,000	-235,000

White Blood Count			
	Pre	Post	Difference
Placebo	10,187.50	9,975.00	-212.50
Ritalin	9,537.50	8,875.00	-662.50
Wyamine	10,862.50	10,475.00	-387.50

tent was to increase the dosage until patients' behavior level improved as noted by the experimenters' clinical observation or until untoward physical effects were manifested. The dosage of

placebo varied from a beginning average of 75 mg. to a final average of 560 mg. per patient per day, that of Ritalin from 40 mg. to 250 mg., and that of Wyamine from 50 mg. to 350 mg.

Discussion

The results with regard to behavior, although obviously inconclusive due to the small number

GRAPH 3. WYAMINE GROUP.

Results

The patients' behavior was the same at the end of the experiment as at the beginning for all three groups as noted by behavior ratings and clinical observation.

As can be seen from Table I, there was no apparent significant change in red blood count, white blood count or hemoglobin between the beginning and end of the experiment in any of the three groups.

As can be seen from Graph 1, the placebo group varied from an average beginning blood pressure of 143/90 to a final blood pressure of 116/78. Graph 2 shows the Ritalin group varying from 114/79 to 139/90. Graph 3 indicates that the Wyamine group varied from 131/88 to 129/87.

of patients involved and the relatively short period of drug administration, discouraged the authors from carrying out a full scale experiment at this time. The most interesting result of this study was a totally unexpected one. Blood pressures of the patients receiving the stimulant drugs showed a slight increase in comparison to those receiving placebo, but this increase was in no way as drastic as would be expected with the dosages of the drugs given. Although further research is certainly indicated using normal subjects, it can be stated that relatively massive dosages of Ritalin and Wyamine have no undue, untoward effect on the blood pressure of the regressed mental patient.

(Continued on Page 839)

Respiratory Acidosis

R. DREW MILLER, M.D.
Rochester, Minnesota

ALL TOO frequently pulmonary function is considered as independent of total body function. Just as patients with pulmonary tuberculosis have been isolated from other medical patients, so has the ventilation of the lungs been considered in an isolated category by many clinicians.

A study of respiratory acidosis and the acid-base balance of the body affords an excellent opportunity to appreciate the relationship of alveolar ventilation to the general metabolic demands. Although many organs, particularly in the digestive system, secrete fluids with a pH considerably different from that of the circulating fluids, the lungs and the kidneys carry the burden of maintaining the pH of the internal environment at a relatively steady level (Fig. 1). The lungs are the agency of immediate stabilization, as pulmonary adjustments may be made in minutes whereas renal adjustments require hours or days.

Significant reduction of the functional reserve of the lungs or the kidneys limits their ability to adjust to unusual metabolic demands. Transient disturbances in acid-base balance then result during such demands. As function becomes more severely limited, chronic acid-base imbalance may occur at rest with minimal metabolic requirements and defy even the most energetic therapeutic measures.

Inadequacy of alveolar ventilation causes retention of carbon dioxide, which is accompanied by respiratory acidosis. This disorder often is considered to be associated with primary pulmonary disease, particularly diffuse obstructive emphysema. However, respiratory acidosis of a transient nature may be seen much more frequently in patients with normal lungs if one considers hypoventilation during general anesthesia. This problem confronts the anesthesiologist continually unless adequate ventilation is provided. It must

be remembered that alveolar ventilation is related to the tidal volume less the dead space.

Sudden Acidosis in Generally Normal Lungs

In considering the mechanisms of CO₂ retention and respiratory acidosis it is appropriate to begin with conditions in a normal lung which is being ventilated with a relatively high, although not perfect, degree of evenness. If the respiratory center is depressed by a general anesthetic agent or excessive doses of opiates or sedatives, mechanical assistance must be maintained until the respiratory center recovers. If the patient is breathing room air, cyanosis gives warning of inadequate ventilation and spurs attendants into action. This obvious indicator is not present, however, if high tensions of oxygen are being administered. Those responsible for the patient's care during anesthesia must be made cognizant of the dangers of respiratory acidosis despite the normal color of the skin and mucous membranes in this circumstance.

Chronic Acidosis and Renal Buffering

A variety of diseases involving the thoracic wall and diaphragm and the accessory muscles of respiration lead to a chronic state resembling temporary pharmacologic depression of the respiratory center. Among these are the residual paralysis of poliomyelitis and diseases with similar neuroanatomic distribution, severe kyphoscoliosis, and extreme obesity.¹ In these conditions the bellows mechanism producing tidal volume is inadequate as a consequence of decreased muscular strength or mechanical impairment preventing efficient muscular activity. Inadequate CO₂ elimination allows the alveolar CO₂ tension to rise, with a similar rise in CO₂ tension in the blood. The buffering action of the kidney eliminates chloride ions, resulting in partial restoration of the normal ratio of bicarbonate to CO₂ and normal pH.

From the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

The related functions of the lungs and kidneys in maintaining a normal pH of the blood are most simply expressed by the Henderson-Hasselbalch equation.

$$\text{pH} = \text{pK} + \log \frac{\text{BHCO}_3}{\text{H}_2\text{CO}_3}$$

(B=base, such as sodium or potassium)

Since CO_2 moves in and out of various body compartments in response to difference in partial pressure (pCO_2), this term can be substituted in the formula because for each unit of partial pressure expressed as millimeters of water 0.0301 millimole of CO_2 dissolves in water to form H_2CO_3 .²

$$\text{pH} = \text{pK} + \log \frac{\text{BHCO}_3}{0.0301 \cdot \text{pCO}_2}$$

It may be seen that an increase in pCO_2 without change in BHCO_3 will cause the pH to decrease, leading to respiratory acidosis. Then as the BHCO_3 increases, the normal ratio of 20 to 1 is approached; and the acidosis may become partially offset by this buffer system.

Clinically, it is important to have some information about the unknown factors in this equation—the pH, the bicarbonate (or alkaline reserve), and the CO_2 . Accurate knowledge of any two would allow calculation of the third; but unfortunately, only the alkaline reserve can be measured with facility in most clinical laboratories. A high alkaline reserve could indicate metabolic alkalosis or partially compensated respiratory acidosis; the alkaline reserve could be normal in uncompensated respiratory acidosis. Knowledge of the clinical course of the patient is therefore an essential. If conditions which could lead to alveolar hypoventilation are present, then a high alkaline reserve would support a diagnosis of respiratory acidosis. If acute complications or changes appear which decrease elimination of CO_2 by the lungs or increase production of CO_2 by the body, or have both effects, then the alkaline reserve may be normal if the renal mechanisms have not had time to act. Such conditions as pneumonia, severe bronchitis or bronchospasm, or marked exertion with limited ventilatory reserve might lead to a transient rise in pCO_2 without compensatory rise in BHCO_3 if adequate elimination of CO_2 is promptly restored.³

Acidosis in Primary Pulmonary Disease

These disturbances are much more complex in primary pulmonary disease. Carbon dioxide retention occurs when diffuse emphysematous

ELEMENTS OF ACID-BASE REGULATION

Fig. 1. The maintenance of normal pH of body fluids depends on the rate at which the lungs eliminate CO_2 and the kidneys eliminate the various fixed electrolytes in relation to their concentrations within the circulating fluids.

changes are present. Diffuse interstitial fibrosis, although characterized by hypoxia associated with impaired diffusion of oxygen, is not accompanied by CO_2 retention because diffusion of CO_2 occurs much more rapidly across the alveolocapillary membrane and because alveolar ventilation in interstitial fibrosis is usually equal to or actually greater than in normal lungs. If significant emphysema complicates some types of pulmonary fibrosis, CO_2 retention may follow.

The variation in turnover rate of gases in various alveoli and other air spaces in emphysematous lungs is great. Large portions of the lungs are underventilated, but in other portions the alveoli are actually hyperventilated. By this compensatory mechanism CO_2 may be adequately eliminated from the lungs even in the presence of hypoxia. The balance can continue as long as enough hyperventilated alveoli are being perfused with an adequate amount of mixed venous blood. Once the proportion of the lungs which is underventilated becomes so large that hyperventilated and perfused portions cannot compensate for underventilated portions, CO_2 retention and respiratory acidosis ensue (Fig. 2).

If this decompensation occurs as a result of

bronchopulmonary infection, retained secretions, or bronchospasm, energetic treatment with appropriate antibiotics, oxygen, and bronchodilators, and mechanical assistance and exsufflation if necessary, may reverse the trend.³ But if reten-

tion of CO_2 is chronic in the absence of these complications, the problem is even more difficult. The potential dangers of aggravating the hypoventilation by administration of high tensions of oxygen to patients with severe emphysema are well known. That the respiratory center in these patients loses sensitivity to increased CO_2 in the blood is generally appreciated also, although the mechanism by which this occurs is not clear. In this advanced stage of emphysema the work of breathing is many times normal, even when at rest with a relatively small minute ventilation. This increased work places an increased metabolic demand on the lungs for supplying oxygen and eliminating CO_2 . Thus an attempt to increase the ventilation to eliminate CO_2 may conceivably result in production of more CO_2 than the inefficiently ventilated lung can eliminate. Usually, at this stage, a relatively minor respiratory infection or cor pulmonale may lead to the patient's demise.

Fig. 2. In pulmonary emphysema the wide variation in ventilation of various alveoli may lead to inadequate oxygenation of the mixed venous blood perfusing the underventilated alveoli and incomplete elimination of CO_2 . If hyperventilated and perfused alveoli are numerous, sufficient CO_2 may be eliminated, thus compensating for the retention of CO_2 in other areas. However, oxygenation of the blood can only reach normal (essentially complete) and thus cannot compensate for incomplete oxygenation in the hypoventilated areas.

Ligneous Appendicitis Simulating Malignancy of the Cecum

MALCOLM G. GILLESPIE, M.D.

ROBERT H. LaBREE, M.D.

SHERWOOD L. LARSON, M.D.

Duluth, Minnesota

IT IS with interest that one may note the rarity of a nonspecific granulomatous condition involving the appendix, cecum, terminal ileum and neighboring structures. This entity has been described under several titles such as "Infectious Granuloma,"¹ "Ligneous Inflammation of the Cecum,"² and "Nonspecific Granuloma."³ The clinical impression is frequently malignancy of the cecum or appendiceal abscess. The preoperative diagnosis in two of the cases to be reported was carcinoma of the cecum and in the third case, appendiceal abscess or malignancy. This preoperative impression was based on the presence of a hard, firm mass in the right lower quadrant. However, the presumptive diagnosis in the first two cases was not supported by anemia or characteristic x-ray changes. In retrospect, the absence of anemia and lack of usual x-ray deformity of the cecum pretty well ruled out malignancy.

The pathological aspects of Ligneous appendicitis have been ably described by Wilson, et al.^{4,5} Therefore, only brief comment is needed to explain the principal pathologic condition involved in the production of these massive granulomatous changes of the ileocecal region. Basically, the process centers around an initial inflammation with edema of either the appendix, the cecum or both. If the edema is sufficiently great to promote local, partial obstruction of the area, the secretory nature of the mucosal surfaces further enhances the tenseness of the involved structures and promotes the hard, indurated appearance.

In two of the cases presented, the appendix seemed to be the focal point of the surrounding inflammatory reaction. In the third and fourth cases, not only was the appendix involved but there was also a sinus tract between the periappendiceal mass and the cecum. The microscopic appearance of the excised tissues from all four

cases showed extensive fibrosis with marked scarring of all elements sectioned. There were unusually large amounts of inflammatory infiltrate made up of lymphocytes and plasma cells. No malignant changes were found in any of the sections of the primary masses or regional lymph nodes.

Report of Cases

Case 1.—This sixty-seven-year-old white woman was first seen on August 30, 1954. For four months, the patient had complained of constipation and intermittent pain in the right lower quadrant of the abdomen. She had lost 15 pounds of weight. There was no vomiting and no blood seen in the stools. Her past health was always good except for periodic bouts of constipation.

On physical examination there was a firm mass in the right lower quadrant which on bimanual vaginal examination was estimated to measure between 10 and 12 centimeters in diameter.

The hemoglobin was 11.8 grams, the red blood count 4,140,000, the white blood count 10,000. A differential white blood count revealed 77% segmented polymorphonuclear cells. The urine was negative to examination.

X-rays of the colon and terminal ileum, which the patient brought with her, showed the outline of the cecum to be more irregular than usual.

The diagnostic impression was carcinoma of the cecum, with appendiceal abscess also considered as a possibility.

The patient was admitted to the hospital and on September 3, 1954, abdominal exploration was carried out through a right vertical midrectus incision. A large mass was found to involve the cecum and appendiceal region and was attached firmly to the abdominal wall. So firmly was this attached that it was necessary to excise a portion of the peritoneum of the abdominal wall. This allowed mobilization of the mass and the right colon. A right colectomy was performed. An ileo-transversecolostomy was used to re-establish the continuity of the intestinal tract.

The postoperative course was uneventful and the patient was dismissed from the hospital ten days after surgery.

Pathological examination revealed a huge inflammatory mass surrounding the appendix with the latter structure showing subacute appendicitis.

Case 2.—A seventy-six-year-old white man was first seen on November 9, 1954. The chief complaint was a large mass in the right lower quadrant of the abdomen.

Presented at the meeting of the Minnesota Surgical Society, Duluth, Minnesota, July 19, 1957.

From the Department of Surgery, The Duluth Clinic, Duluth, Minnesota.

This had been present for six months and was gradually enlarging. He had complained of alternating diarrhea and constipation for three weeks prior to entrance to the hospital and during this same time had complained of generalized abdominal cramps. Weakness and increasing anorexia had been noted for three months. He had lost thirty pounds over the six-month period.

Physical examination revealed a fairly well-preserved man of seventy-six years. The major findings were a very firm, irregular mass in the right lower quadrant of the abdomen, estimated to measure about 15 cm. in diameter, non-tender nodes in the right inguinal region, and mild tenderness on palpation of the mass. Rectal examination revealed a Grade II enlargement of the prostate with one stony, hard nodule palpable in the right lobe.

Laboratory examination revealed a hemoglobin of 12 grams, red blood count 4,290,000, white blood count 10,500. The differential white blood count revealed 77% polymorphonuclear cells.

X-ray of the colon revealed diverticulosis of the descending colon and sigmoid. The cecum did not fill well but showed no deformity.

The diagnostic impression was carcinoma of the cecum and the prostate.

On November 22, 1954, an exploratory laparotomy was performed. A large tumor, in the region of the cecum, was attached firmly to the anterior and lateral abdominal walls and the urinary bladder. The impression after examination and palpation of the mass was that it was malignant; therefore, a right colectomy, including the attached abdominal wall and a portion of the wall of the urinary bladder, was carried out. The urinary bladder was closed in layers and decompressed by means of a catheter brought out in the suprapubic region. The intestinal continuity was re-established by an end-to-end anastomosis of the ileum to the transverse colon.

The postoperative course of this patient was relatively uneventful, and he was released from the hospital on the twenty-second day following surgery. The pathologist reported a granulomatous process. The diagnosis was perityphlitis ligneum and pericecal granuloma.

About one month later, the patient was readmitted to the hospital complaining of abdominal pain, nausea and vomiting which had been present for three or four days. X-ray studies showed a gas-filled loop of small intestine. Subsequently, he was operated upon and a gangrenous loop of ileum was resected. The patient expired February 1, 1955, as a result of fistula formation and a terminal bronchopneumonia.

Case 3.—A thirty-year-old white man was first seen on October 15, 1956. The present complaint dated back to September 1, 1956, at which time he began to notice intermittent cramping pain in the right lower quadrant of the abdomen, not associated with nausea, vomiting or change of bowel habits.

The past history was only significant in that in August, 1956, he had infectious hepatitis. His recovery from this was rapid.

Physical examination revealed a 10 to 12 cm. hard,

somewhat tender, mass in the right lower quadrant of the abdomen. It was not movable.

Laboratory examination revealed a hemoglobin of 12.3 grams, RBC 4,180,000, WBC 7,650. A differential white blood count showed a normal distribution of white blood cells. Urinalysis was negative. Sedimentation rate was 24 mm./1 hr.

X-ray studies of the gastrointestinal tract were negative with the exception of the mass in the RLQ which prevented filling of the cecum with barium.

The diagnostic impression was appendiceal abscess or malignancy.

On October 22, 1956, an abdominal exploratory was performed. The large mass was found to involve the abdominal wall, the cecum, the urinary bladder and the sigmoid. The mass was very hard and firmly attached. A right colectomy, including the peritoneal attachments, and excision of a portion of the wall of the urinary bladder was accomplished. These attachments were so firm that they had to be divided with the scalpel. Intestinal continuity was re-established by side-to-side ileo-transverse colectomy. The postoperative course of this patient was uneventful and he left the hospital on November 13, 1956.

The pathological diagnosis was subacute suppurative appendicitis. There was an enormous periappendiceal chronic inflammatory mass with a sinus tract between the periappendiceal mass and the cecum.

These three cases are of particular interest because the preoperative impression strongly suggested malignancy of the cecum. In each case, the correct diagnosis was made only after right colectomy. It was only after the specimen was in the pathologist's hands that the true nature of the disease was realized.

Case 4.—A sixteen-year-old boy came to the clinic, June 4, 1957. His present illness dated back to March of 1957. The presenting complaints were: malaise, poor appetite, loss of weight, and occasional dizzy spells.

In March, he missed a few days of school because his stomach bothered him, and in mid-April he developed cough, anorexia, and fatigue. The cough improved after a week, but his complaint of fatigue persisted. His physician told him that he could have rheumatic fever. He was hospitalized from April 26 to May 4, and during that time he improved. A week or so after leaving the hospital, he noted a recurrence of his nausea, and he complained of increased warmth and light-headedness on standing.

Physical examination revealed a slight nasal congestion, a questionable enlargement of the spleen, a sedimentation rate of 20 mm/1 hr., and white blood count of 16,400. A differential white blood count revealed 65 per cent polymorphonuclears and 25 per cent lymphocytes. The urine showed 3 red blood cells per high-powered field.

He was hospitalized on June 10. The intern's diagnostic impressions were: (1) infectious mononucleosis, (2) rheumatic fever, (3) brucellosis. A chest x-ray examination gave negative findings. Heterophile test was reported negative. On June 12, he had an exacerbation of his illness, complaining of abdominal cramps,

vomiting and tenderness and muscle spasm on the right side of the abdomen. Surgical consultation was requested on June 13, and the diagnosis at this time was acute appendicitis walled off by omentum or a walled-off appendiceal abscess, and partial small bowel obstruction.

On June 14, he was operated upon under spinal anesthesia. A mass could be felt in the right side of the abdomen. A vertical incision was made over this area. Exploration revealed a moderately dilated ileum. There was a firm tumor mass involving the terminal ileum, cecum, and appendix. The distal inch of the appendix could be seen protruding from the mass. There was no pus seen. Our impression was that this represented a granuloma of some type although a lymphomatous tumor was also considered. A right colectomy was decided upon and carried out.

The pathologist reported a 9 x 6 x 10 cm. firm mass composed of lower ileum, cecum, appendix, and ascending colon. Upon opening the specimen, two superficial ulcerations were seen, one 2 cm. in diameter in the lower ileum and another 5 cm. long extending from the ileo-cecal valve into the cecum. This mass was made up of dense fibrous and fatty tissue in the center of which was the appendix. There were several fistulous tracks into this fibro-fatty mass filled with pus and communicating with the lumen of the appendix. The diagnosis was: organizing pericecal abscess originating as a subacute suppurative appendicitis with perforation.

The patient made an uneventful recovery and left the hospital on the eighth postoperative day.

Comment

The striking features noted at surgery in each case were the hardness and irregularity of the mass together with the very firm attachments to the abdominal wall and the urinary bladder and, in the third case, to the sigmoid.

Because of our experience and operative findings, we believe that right colectomy is the logical operative procedure. Local excision would seem impossible in view of the extensive and firm attachments. The end result of an ileo-transverse colostomy only is open to question.

EFFECTS OF STIMULANT DRUGS ON REGRESSED PATIENTS

(Continued from Page 833)

Summary

Twelve of the most regressed men patients in an 1800-bed mental hospital were divided into three groups. One group received placebo; another group, Ritalin; and a third group, Wyamine for a period of two weeks. Dosages were minimal to begin with and were rapidly increased to relatively high levels. Behavior ratings were done, clinical observations were made and blood pressure and blood studies were carried out.

Conclusions

1. Systolic and diastolic blood pressures do not show a marked increase at relatively high dosages of Ritalin or Wyamine in regressed mental patients.

2. There was no difference in behavior noted in the small group of patients treated.

3. White blood count, red blood count and hemoglobin were relatively unaffected by the drugs given.

Acknowledgments

We are indebted to the Wyeth Laboratories for furnishing the Wyamine and placebo; to Ciba for the Ritalin; and to John Hamlon, M.D. and the Psychiatric Aides on the ward for various types of assistance.

Constitutional Hepatic Dysfunction

An Unusual Cause of Jaundice in Childhood

STEPHEN D. MILLS, M.D.
Rochester, Minnesota

JAUNDICE at any age commands attention.

Its causes vary in kind and severity from infancy to adult life, and it generally has a serious connotation. Jaundice may be classified into three types: hemolytic, intrahepatic and extrahepatic. However, there is a benign kind of jaundice in which the indirect-reacting serum bilirubin is increased and which is not of serious nature and is compatible with reasonably good health. This condition is known by a variety of names and was first described in the early part of this century by Gilbert and associates¹ as simple familial cholemia. The name that best describes the condition, constitutional hepatic dysfunction, was suggested by Comfort² in 1935. Other names offered by various authors include simple chronic icterus, familial cholemia, familial nonhemolytic jaundice, and constitutional hyperbilirubinemia. Meulengracht³ described a similar condition as icterus intermittens juvenilis in 1939, and reviewed his experience in twenty-nine cases in 1947.⁴ Recently, Dubin and Johnson⁵ reported twelve cases of chronic idiopathic jaundice with an unidentified pigment in the hepatic cells; the condition they described differs substantially from constitutional hepatic dysfunction in that it is characterized by an increase of direct-reacting serum bilirubin. They had the advantage of biopsy of the liver in five of their patients. They were able to find only twenty-four cases in which biopsy of the liver had been reported in any of the above-mentioned conditions. They felt that several ill-defined types of jaundice were probably included such as familial nonhemolytic jaundice, the jaundice accompanying gastrointestinal diseases such as peptic ulcer, gastritis and colitis, and finally

jaundice resulting from the residue of viral hepatitis.

A paper by Rozendaal, Comfort and Snell⁶ in 1935 offers a clear-cut clinical picture of the condition known as constitutional hepatic dysfunction and cites the prior publication on the subject by Gilbert and associates. Rozendaal and co-workers studied 214 patients seen at the Mayo Clinic in the year 1930-1931 in whom the concentration of serum bilirubin was increased to values ranging from 2 mg. up to 7 mg. per 100 cc. of blood. Clinical jaundice usually appears at a concentration of 3 mg. per 100 cc. Normally there is a balance between the formation of bilirubin by the reticuloendothelial cells of the liver and its excretion by the hepatic cells. This balance is upset by disease which increases the formation or decreases the excretion of bilirubin. Constitutional hepatic dysfunction is presumed to be due to an inborn defect of the hepatic cells in the excretion of bilirubin, that is, to a high threshold of excretion. Consequently examination of the blood discloses an increase of indirect-reacting serum bilirubin without other evidence of hemolytic disease such as spherocytosis, splenomegaly, increased fragility of the red cells, reticulocytosis or increased activity of the bone marrow, which are found in congenital hemolytic jaundice.

The jaundice may be familial and may begin in early childhood. Males are affected predominantly. It may be constant or intermittent and has a tendency to appear or increase following emotional upsets, bilious or migraine attacks, or with constipation or diarrhea. In some instances there is evidence of previous hepatic disease or injury. There are usually no symptoms except fatigue and asthenia associated with the jaundice, and these do not adversely affect the health of the patient. The only abnormal laboratory finding is an increase of indirect-reacting serum bilirubin. The liver and spleen are not enlarged. The jaundice is usually mild or it may be latent.

*Read at the meeting of the Southern Minnesota Medical Association, Lake City, Minnesota, September 9, 1957.

Dr. Mills is in the Section of Pediatrics, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Constitutional hepatic dysfunction may be confused with hemolytic disease, as well as diseases of the biliary tract and liver. This may lead to unnecessary restrictions on the patient and unnecessary surgical and medical procedures. There is no reason for splenectomy, cholecystectomy or choledochostomy. No benefit results from medical treatment for hepatitis or cirrhosis of the liver. The presence of this disorder should not deny the patient the right to be insured. It is entirely possible that cholecystic disease may be found in some of these patients as they progress and they should be observed for this condition.

As constitutional hepatic dysfunction has received scant attention in pediatric literature, it seems advisable to call it to the notice of those who deal with children in order to emphasize its benign nature. The following case illustrates the condition.

Report of Case

A five-year-old adopted boy had been in good health until the age of three years when it was first observed that he had jaundice accompanying acute infection of the respiratory tract. The yellow color of his skin at that time was attributed to carotinemia. Further tests were done because he had fever and nausea and was ill for a month. Infectious hepatitis was diagnosed, and hepatomegaly noted. He became well until a year later when his jaundice returned with fever and nausea, and his liver again showed some enlargement. He had pneumonia with this attack, was hospitalized for one week, and then remained home in bed for two months with jaundice and continued enlargement of his liver. Thereafter he had recurrent episodes of jaundice associated with sore throat. A short time before he was brought to the Mayo Clinic he had been hospitalized for the same condition and a diagnosis of infectious mononucleosis with associated hepatitis had been made. He had received various antibiotics, vitamin K, liver extract and a low-fat, high-caloric diet and his activity had been restricted. He had been kept out of school. His stools had been of normal color but his urine had been darker at times when he had jaundice. The boy denied feeling tired or listless when jaundiced.

On admission at five years and ten months of age the boy appeared to be well developed and well nourished. He had a slightly yellow color of his skin and sclerae. His temperature was 99° F. orally, his blood pressure 98 mm. of mercury systolic and 60 diastolic and his pulse rate 100 beats per minute. Examination of his ears, nose and throat gave negative results. His tonsils were small. His heart and lungs were normal. The edge of the liver was at the right costal border. His spleen was not palpable.

The urine had a specific gravity of 1.024, it was acid, and it contained no albumin, sugar or bile. Micro-

scopic examination of the sediment showed no abnormalities. A 24-hour collection of urine contained 0.66 mg. of urobilinogen. The hemoglobin content was 12.8 gm. per 100 cc. of blood. The erythrocytes numbered 4,140,000 and the leukocytes 5,700 per cubic millimeter, of which 36.5 per cent were lymphocytes, 4 per cent monocytes, 58 per cent neutrophils, 0.5 per cent eosinophils and 1.0 per cent basophils. The reticulocytes represented 0.7 per cent of the cells. The sedimentation rate by the Westergren method was 5 mm. in 1 hour. Blood smears were not diagnostic. No spherocytes were noted. In the fragility test, hemolysis of the red cells commenced in a 0.44 per cent salt solution and was complete in a 0.28 per cent solution. A Coombs anti-globulin test gave negative results. Serum bilirubin determinations were negative by the direct method and gave values of 3.65 and 3.84 mg. per 100 cc. by the indirect method. The prothrombin time was 17 seconds. The sulfobromophthalein-retention test gave negative results. The zinc sulfate turbidity test gave a value of 9 units and the cephalin cholesterol flocculation reaction was negative. X-ray examination of the thorax gave negative results as did the tuberculin test with single-strength purified protein derivative. Serum electrophoresis showed a total protein content of 6.5 gm. per 100 cc., made up of the following fractions: albumin, 3.90 gm.; alpha globulin, 0.25 gm.; alpha₂ globulin, 0.63 gm.; beta globulin, 0.82 gm.; and gamma globulin, 0.90 gm.

The history and findings fitted the description of constitutional hepatic dysfunction as outlined by Comfort in 1935. The parents of the boy were reassured about the benign nature of the disorder, all restrictions of diet and exercise were removed and no medication was suggested. The hematologist could find no evidence of a hemolytic type of jaundice. Follow-up information since the boy's dismissal indicates that he is in excellent health. His jaundice has recurred but he has continued all his normal activities.

Summary

Constitutional hepatic dysfunction is a benign condition characterized by intermittent jaundice due to increase of indirect-reacting serum bilirubin. It is presumably due to an inherent defect in the hepatic cell in which the threshold for excretion of indirect-reacting bilirubin is raised. Patients with this condition would be spared needless operations and medical treatment if it were correctly diagnosed and the hopeful outlook appreciated.

Infertility—A Family Unit Problem

W. H. MASTERS, M.D.
St. Louis, Missouri

THERE is no problem of more innate concern to the family unit than the basic distress of a barren marriage. The mature female's sense of fulfillment, derived only from a growing family, is replaced by unbelievable levels of immature pettiness or self-pity. The fundamental male demand to protect and provide is dissipated by lack of dependency. In essence, an involuntary barren marriage is built on the psychological sand of unit frustration, rather than the rock of family cohesiveness and growth.

Any approach to the problem of the infertile family unit must be divided into two definitive categories. Of primary importance, is the dissemination of fundamental conceptive information. Of equal import, yet of secondary consideration, is the demand for infinite detail in the infertility work-up. The most efficient organization of a patient's and physician's time is required to deal with the need of disseminating definitive medical information, and subjecting the infertile unit to the infinite detail of a well-planned sterility work-up.

All couples seen by the Infertility Service of the Washington University School of Medicine are treated on a purely private patient basis. These family units must, however, volunteer complete cooperation of both husband and wife for at least a year from the onset of definitive medical evaluation. The necessity of treating the infertile couple as a single biological unit has long been well recognized.¹ It probably matters little which medical discipline undertakes to treat the infertile family unit. However, it is of major import to hold this unit closely together. Early rapport, established between investigator and unit members, is of inestimable value in relieving the basic tensions inevitably associated with the exhaustive investigative procedures necessary for any complete evaluation of an infertility problem.

From the Department of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, Missouri.

Presented at the annual meeting of the Minnesota State Medical Association, Saint Paul, May 15, 1957.

The Intake Interview

Certainly the most universally neglected, yet the most rewarding practice associated with infertility investigation, is an initial informal interview with both members of the family unit. This appointment should be arranged outside of regular office hours, because the interview usually takes a minimum of an hour's time. The interviewer must place the couple at ease at the outset of the discussion. As a possible introductory wedge, one might mention the high incidence of sterility (one infertile couple in every eight marriages).² It is of real psychological import to bring the family unit to realize that they comprise no medical oddity, but are, indeed, involved in an unfortunately all-too-common situation.

The first step in the intake interview is a detailed discussion of the basic essentials of reproduction, as they apply to the individual family unit.³ Of course, it is of primary importance for the infertile couple to know when to have intercourse (in relation to the theoretical ovulation time). Certainly, the optimum intercourse frequency (to maintain best possible sperm production) must be described. The most effective unit positioning in intercourse (to develop the best anatomical chance of conception) should be mentioned and defined in detail. A lead discussion to this detailed sex talk is provided by a complete explanation of the basic physiology of the human genital system, and a detailed account of the phenomenon of conception. In essence, the physician should presume that the average infertile family unit does not know where babies come from, and must present the true story in complete and frank detail. Rapport established during this sex talk will be of a major aid during the tension-filled phases of any subsequent infertility work-up.

In addition to the advantage of establishing rapport with the infertile family unit, a detailed discussion of how, when and how frequently it is best to have intercourse will be infinitely rewarding in terms of pregnancy accomplished.

Over an eight-year period, one out of every eight couples who, so far as they knew, had never previously conceived, were able to accomplish conception within a three-month period following the basic, detailed sex discussion.⁴

It is also important during the intake interview to describe the steps to be taken in carrying out a complete infertility evaluation in the event the family unit is unable to conceive during the subsequent three-month trial period. Once an infertile unit has been presented with a complete plan of investigative action, their cooperation increases by leaps and bounds. It is also certain that unit confidence developed under the guise of feeling "something is being done," will relieve a great deal of the marital tension constantly noted in the female partner. Possibly, many of the women who conceive subsequent to the basic sex talk do so as much from tension relief, as from putting into practice the basic information of how, when, and how frequently to have intercourse.

If the infertile unit is unsuccessful in achieving conception in a three-month trial period subsequent to the intake interview, they have only to notify us of the initial day of any menstrual period in order to start the complete clinical and laboratory infertility evaluation. Also they are instructed to have intercourse as the period is expected or has just started, so that the male partner may be evaluated (with not less than three nor more than five days of continence)⁵ during his wife's menstrual period. This provides the opportunity of evaluating the male at the height of his reproductive prowess, rather than with a too little or too long period of continence, before sperm specimen evaluation. Thus, the male member of the family unit is always the first to be checked.

There are several advantages in conducting the investigation of the male partner before that of his female counterpart. In the first place, it must be presumed that he represents 50% of the bargain. Second, it is obviously infinitely easier to do a complete evaluation of the male than the female marital partner. Finally, it has certainly been true in the past, that many males have confused a suggestion of infertility with a suggestion of impotence. Subsequently, they have refused adequate and effective cooperation with the examiners. The distinction between the infertile and impotent male is completely defined for both hus-

band's and wife's edification during the original intake interview.

Work-up Routine of the Male Partner

The initial procedures of the primary evaluation are (in order): The laboratory determination of a basal metabolic rate, blood count, urinalysis, roentgenogram of chest; subsequently followed by a complete history and physical examination. In taking the history, such salient factors as the following are discussed and recorded: Age; length of marriage; period of contraception (if any); previous marriages and resulting pregnancies; positioning, frequency or difficulties during coitus; childhood disease (especially mumps with resultant complications), other serious illnesses, operations, venereal disease or general infections; possible radiation exposure; recent marked change in weight; injuries; occupation; diet; drug and alcohol ingestion; and tobacco consumption. This detailed history is followed by a complete physical examination with, of course, emphasis on the lower abdomen, the genitals and the prostate gland. Finally, a sperm specimen is collected for laboratory examination.

Technique

Sperm can be obtained from the human male in at least five different ways. However, only one of these techniques is considered significantly informative to be used by the Infertility Service, (Masturbation Technique).

Withdrawal Technique.—The family unit has intercourse, and as the male feels the ejaculation imminent, he withdraws, and collects the specimen in a clean container. The difficulties involved with this technique are significant. The male frequently loses a few drops of the ejaculate. Since the major sperm concentration is in the first quarter of the male ejaculate, this technique may well result in medical misinformation.

Condom Specimen.—For this technique, intercourse is carried to completion and the ejaculate delivered for laboratory analysis. The difficulties with this technique are of even more concern than the withdrawal technique. It is impossible for the male to remove the condom successfully without a part of the ejaculate remaining on the shaft of the penis. Certainly, the examiner can-

not remove all the ejaculate from the condom. Moreover, both the rubber and the talcum frequently associated with commercially marketed condoms are spermicidal. Thus this technique also is fraught with the possibilities of false information.

Hühner Technique.—In this instance, after the couple has intercourse, the wife visits the physician a few hours after coitus for an aspiration of the cervical mucus. This technique, in company with both the above methods, will certainly demonstrate major discrepancies in sperm production, and will also describe immediate sperm motility. If dead sperm are found in cervical mucus, however, this technique does not delineate between the possibility of the sperm being ejaculated dead and the possible antipathy to these particular sperm by the marital partner's cervical mucus.

Prostatic Massage.—Rectal massage of the prostate will certainly provide sufficient material for a sperm count. Since the first few drops of the ejaculate are effectively obtained by this technique, it is used by many examiners as a quick office procedure technique. Despite the clinical ease with which this technique is carried out, it should be noted that one of the least important factors in the evaluation of the male's sperm specimen is the actual sperm count.

Masturbation Technique.—This is the only technique acceptable to the Infertility Service, when the responsibility of defining male fertility is at stake. The entire ejaculate may be easily obtained, under relatively sterile conditions. Once satisfactorily obtained, the complete sperm specimen is evaluated in detail over a twenty-four hour period.

The semen specimen is allowed to liquefy before a culture is taken. Analysis is then performed following essentially the criteria offered by Falk and Kaufman.⁶ Evaluation is made according to total volume, viscosity, turbidity, count per unit volume, total count, initial motility and morphology.⁷⁻¹⁶ Finally, and most important, subsequent sperm motility is defined throughout a twenty-four hour observation period. Certainly, the greatest investigative emphasis is placed on sperm motility and sperm longevity. Most observers today consider these factors as the most important definitives of semen quality. It matters

little how high the initial sperm count is, if adequate numbers of normal appearing sperm do not live for a sufficient time, and swim effectively enough to reach the ampulla portion of the fallopian tubes, where fertilization actually occurs. Without these two characteristics of adequate motility and longevity (eighteen to twenty-four hours *in vitro*) demonstrable in a sperm specimen, the individual male is considered sterile. When white blood cells are noted during the initial sperm count, the sterile specimen is cultured. If either coliform or anaerobic streptococci are found, the individual male is treated by the appropriate antibiotic compound.¹⁷

Routine Examination of the Female Partner

If the male is not completely defined as sterile, the female is then studied. The initial investigation of the male partner is usually completed by the fifth or six day of the individual menstrual cycle under analysis. The wife is seen alone on the sixth or seventh day of this first cycle of study. If one can move directly from evaluating the male to evaluating the female partner, continuity is established, and the sense that "something is being done" is brought afresh to the couple's consciousness. The press of previous medical commitments, too often delays the work-up of either partner. The initial enthusiasm engendered by the intake interview is dissipated. Once lost, such enthusiasm is hard to recreate.

A complete history is taken with deliberate repetition of certain points in the husband's history. The following pertinent points are discussed: Previous professional advice, including intercourse timing; frequency and positioning; difficulties of coitus; menstrual history; period of present marriage; period of contraception; period of pregnancy trial; history of previous marriage and resultant pregnancies; temperature charts results; childhood diseases; serious illnesses; operations; pelvis infection; venereal diseases; radiation exposure; recent marked change in weight; injuries; occupation; diet; drug and alcohol ingestion; and tobacco consumption. A thorough physical examination is then completed with particular attention directed toward careful examination of the pelvis.

The patient is instructed in the technique of taking daily vaginal smears throughout the investigative menstrual cycle. Smears are taken at

approximately the same time every day, except during the presumptive ovulatory phase. During this week, slides are taken twice a day, at twelve-hour intervals. Since correlative studies are being conducted in all cases with basal temperature variations, the patient is given a prepared chart for recording temperatures, and is taught to take daily, basal, rectal temperatures. The value of both vaginal smears and basal temperature changes as possible ovulatory indices is explained to the patient.

Within the next five days, the female partner is seen for physical and laboratory evaluation. First, she is exposed to a laboratory schedule involving a basal metabolic rate, complete blood count, urinalysis and roentgenogram of her chest. Hysterosalpingography is also scheduled, the time chosen to fall between the end of the menses, and the presumptive ovulation date. This timing obviates the possibility of extrusion of loose endometrial tissue into the peritoneal cavity, or embolism of dye through an open uterine sinus. At the same time, it makes the disturbance of a possible conception highly improbable. There is also the incidental chance, according to numerous reports in the literature, that conception may follow directly in the wake of this test for tubal patency.¹⁸

Immediately prior to the actual dye injection, a culture is taken of the cervical mucus, again in an attempt to describe either coliform or anaerobic streptococcal organisms.¹⁹ If positive cultures are returned, the cervix and cervical canal are directly injected with streptomycin, and the cervical mucus recultured the next month. Occasionally, it requires several such injections to free the cervical mucus of these pathogens. It is impossible to achieve bacteriocidal levels of the antibiotic compound in the depths of the infected cervical glands by the usual technique of parenteral injection.

Finally, routine technique is employed in hysterosalpingography. Fundamentally, this clinic has employed aqueous radiopaque media. The salpingogram is usually done on an outpatient basis. If necessary, antispasmodics or sedatives are given to further the effectiveness of the examination by relieving patient tensions or distress. When the procedure is completed, the wet films are shown to the patient, and explained in detail.

It is important not to waste the possibilities of pregnancy during this first investigative cycle. Ac-

cordingly, from menstrual history alone, the patient is given an arbitrary fertility schedule. Intercourse is scheduled three times at thirty-six-hour intervals, preceded by a three-day period of abstinence.⁵ The schedule is estimated on the basis of the fairly well-accepted fact that ovulation occurs generally fourteen days, plus or minus two days, before the onset of menses.²⁰

The initial work-up of the female is finished at the end of the first complete menstrual cycle with an endometrial biopsy. A Novak²¹ suction curette is used for this. The biopsy is performed within the first few hours after the onset of the menses. It is never performed before the onset of the menses, for fear of the remote but ever-present possibility of disturbing a pregnancy, although it is recognized that menstruation causes a variable degree of loss of morphologic detail. However, the endometrial tissue certainly may be evaluated broadly, if taken within the first three or four hours after the onset of menstrual flow.^{22,23}

At the time of this third and last visit of the wife during the first menstrual month, she presents her vaginal smears taken during the entire cycle. These are stained by the Shorr technique²⁴ and later studied in detail.²⁵ At the next visit, the stained smears are demonstrated and explained to the patient in correlation with the endometrial biopsy sections, temperature chart, and results of the routine laboratory evaluation.

The detail just described represents the initial month's effort with the infertile family unit. Obviously, it is anticipated that the material and information turned up in the first month will determine the course of subsequent definitive investigative procedures.

Fundamentally, four types of sterility problems are encountered in infertility research. In order of frequency, they are: First, the couple which, as far as they know, has never conceived. Second, the couple who rather frequently conceive, with consequent regular abortion. Third, the couple who become sterile after one pregnancy. This family unit describes little or no difficulty in attaining its first conception, but thereafter is unable to achieve a second pregnancy. Fourth, [and finally] (a combination of the second and third), the one-pregnancy couple which, with subsequent conceptions, join the multiple-aborter group.

The handling of each of these problems represents differences in technique; in investigative ap-

proach; and in corrective therapy. Suffice it to say, that an infertility investigation cannot be successfully accomplished without a complete evaluation of the family unit proper, following in general the fundamental techniques described in this paper. Without the basic organization of the initial interview and the detailed initial screening work-up, sufficient information cannot be obtained to tackle successfully any of the four groupings of infertility problems. The rapport established by taking the family unit through a well-organized investigative menstrual cycle, is easily carried over into a more definitive evaluation of the family unit, regardless of which of the investigative groups they join.

It cannot be emphasized too strongly that the mutually stimulative and encouraging aspects of the family unit working together toward the ultimate solution of their common problem is of major importance. This emphasis on co-operative endeavor achieves the family-unit continuity of effort so necessary for the successful termination of any detailed infertility evaluation.

Massive Recurring Bleeding in Regional Enteritis

PHILIP W. BROWN, M.D.

Rochester, Minnesota

OCCULT bleeding from the bowel can be a most perplexing diagnostic problem. When the bleeding is massive and recurrent, the difficulties are multiplied. Even when the cause of the bleeding is discovered, it may not be possible, for a number of complicating factors, to treat it satisfactorily.

Report of Case

History.—The patient whom I wish to present to you is a man, thirty-one years old, who came to our clinic on May 3, 1957. He gave a history of having had recurring hemorrhages from the intestines for two and one-half years. He said he never had vomited blood, but that he would experience a sense of weakness and exhaustion and the urge to defecate, at which time he would pass dark red-to-black, tarry stools. He had no intervening intestinal disturbance at any time. He was not subject to diarrhea or constipation. The only episode of diarrhea in the previous two years which he could recall was an episode which followed the spraying of his trees with an insecticide. He gave no history of anything of significance other than these periodic passings of blood.

The patient is a large, heavy man. In fact, he was heavy at the age of twelve years. In 1953, he weighed 350 pounds, and his height was 5 feet, 11 inches. In that year he had had a curious type of dysphagia, and he decided that he should lose weight. He curtailed his eating so that he did reduce his weight to 255 pounds.

In December, 1954, about the time that the first baby was due to be born to his wife, the patient became very nervous and agitated. At that time he first noted the passage of a black, tarry stool. He had felt no pain, but noted that his pulse was rapid. He was sufficiently prostrated for his family to have him placed in the hospital. A roentgenogram of the stomach disclosed nothing abnormal. Anemia was found. Because of bleeding and the anemia, it was suggested that he might have a duodenal ulcer. A regime for the treatment of ulcer was prescribed for him.

In February, 1955, he passed a series of black-to-reddish-black stools over a period of three days. There-

after, each month for the next several months, there would be a period of one, two or three days in which he would pass black, tarry stools. Studies made in June of 1955 disclosed nothing, and again it was suggested that the patient had a duodenal ulcer, even though an ulcer could not be visualized.

Prior to coming here, the patient had had an episode of bleeding on April 15, 1957. At that time he had lost a quantity of blood sufficient to require the administration of 5 units of blood. Results of various investigations, including roentgenologic examination of the stomach and of the colon (after a barium enema), were negative. He was strongly urged at that time to undergo an exploratory operation.

Clinical and Laboratory Studies.—At the time of the initial physical examination of this patient at the Mayo Clinic he weighed 255 pounds. He looked pale. Other than the excessive weight, nothing abnormal was noted during the physical examination. The value for hemoglobin was 7.9 gm. per 100 cc. of blood, the erythrocyte count was 4,200,000 and leukocyte count 6,000 per cubic millimeter of blood. The bromsulphalein test of hepatic function showed no evidence of retention of dye. The blood group was O, Rh and the factor was positive. Gastric analysis revealed total acids of 32 and free acids of 32. Results of all roentgenologic studies were entirely normal; these studies included a roentgenogram of the stomach, x-ray, roentgenograms of the colon after a barium enema, and a series of roentgenograms of the small bowel.

The patient was seen in consultation by Dr. B. Marden Black, of our section of general surgery. In view of the fact that the patient had sustained at least eighteen definite hemorrhages from the bowel during two and one-half years, and another hemorrhage about three weeks prior to coming to the clinic, plus the persistence of the previously noted anemia, with a value for hemoglobin of 7.9 gm. per 100 cc., we advised the patient to accept operation in the hope that the source of the hemorrhages could be found. In the face of the repeatedly negative results of the various studies carried out, the cause of the bleeding of this patient could only be speculated upon. He agreed to the exploratory operation, and preoperatively he received 1,000 cc. of blood. The usual preparation of the bowel was done.

Surgical Observations.—On May 13, 1957, operation was performed, at which time it was found that a segment of approximately 200 cm. of the lower part of the ileum was involved by skip areas of regional enteritis.

Read at the meeting of the Southern Minnesota Medical Association, Lake City, Minnesota, September 9, 1957.

Dr. Brown is in the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

The lowest lesion was about 15 cm. above the ileocecal valve, and above that site were multitudes of skip lesions, scattered throughout the ascending 200 cm. of bowel. Above the sector involved by enteritis the small bowel felt normal. The stomach seemed to be normal. There was no evidence of any abnormality in the colon.

Postoperative Measures.—In view of the weight of the patient and the extent of the disease, it did not seem wise to carry out an operation involving resection of more than 200 cm. of intestine. Hence, since resection was not feasible, it was advised that he receive the benefit of roentgen-ray treatments, which would consist of irradiation of the four quadrants of the abdomen on successive days. This course was to be repeated at intervals of four or five weeks for a series of three courses. The patient was unable to remain here, and said he would undergo these roentgen-ray treatments in his home city.

I received a telephone call from the patient's wife during the latter part of July of this year; she said her husband was in the hospital again after another hemorrhage. He had sustained two hemorrhages since he left the clinic, but the one for which he had been hospitalized was severe. Blood had been administered to him three times by noon of the day on which his wife called me. She wanted to know what could be done. She said her husband had received only one course of the three courses of roentgen-ray treatments which we had advised. I told her I thought that he should complete the other two courses of roentgen-ray treatments as soon as possible. I said that if bleeding should still continue, we might have to attempt resection, on the basis that the risk of resection would be less than the hazard of bleeding to death. It was a difficult decision to make, whichever way it went.

Comment

The purpose of this report is not so much to discuss regional enteritis as to present an illustration of severe intestinal bleeding, the cause of which cannot be recognized by our usual methods. When we think of causes of intestinal bleeding, in about 70 per cent of cases we are likely to regard such bleeding as arising from a peptic ulcer. In possibly 15 to 20 per cent of cases this type of bleeding may proceed from disease of the liver, and in the remaining cases it is caused by a heterogeneous assortment of such conditions as Meckel's diverticulum, solitary ileal ulcer, hereditary telangiectasia and leiomyomas—to mention a few.

So far as regional enteritis is concerned, it is fortunately a rare disease. In our experience, regional enteritis occurs about once to every ten instances of ulcerative colitis. Furthermore, of 600 patients with regional enteritis studied by Van Patter,¹ thirty-six (6 per cent) had sustained fairly severe intestinal bleeding, although I would say that the patient in our report certainly experienced hemorrhage as severe as any I have ever heard of. Actually, the incidence of 6 per cent for severe melena, just mentioned, is not too much higher than the incidence of bleeding in the presence of peptic ulcer. Of course, hemorrhage from any source is a frightening and dramatic symptom.

Hence, when a patient experiences recurring episodes of hemorrhage for which no cause can be discovered, the bleeding is a particularly great problem. In the patient whom I have described, resection of the 200 cm. of involved ileum may yet have to be done, lest the patient die of hemorrhage. However, as I pointed out, because of the extent of the disease and the excess weight of the patient, resection did not seem the proper procedure at the time we saw him. As to whether roentgen-ray therapy will control the process, we do not know. In our experience with patients for whom resection is not indicated, 20 to 25 per cent of them will derive definite benefit from irradiation therapy. On the other hand, in an occasional case, irradiation may even cause or increase bleeding, so that the physician must be alert to such a possibility.

We have urged this particular patient to maintain a high intake of proteins but to curtail calories in an effort to bring about loss of another 50 pounds. If this reduction is achieved, and if bleeding persists after the prescribed courses of roentgen-ray treatment have been completed, then resection surely will be attempted.

Fractures and Dislocations of the Hand and Fingers

MALVIN J. NYDAHL, M.D.

Minneapolis, Minnesota

WHILE all of the joints of the upper extremity are important, an injury to any one of them can be fraught with danger. The most critical are those of the fingers and thumb. This is particularly true with respect to the thumb, index, long and ring fingers. The little finger is useful but one can get along without it. Loss of motion of any of the joints of the fingers can be of great economic importance. It is sometimes difficult to avoid this complication, and everything should be done to maintain and regain motion of the joints. The injured finger or fingers should be immobilized, but not the uninjured members. By immobilizing the injured finger, whether it be a sprain, fracture or dislocation, the torn structures are allowed to heal and traumatic exudation is allowed to subside with consequent better chance of recovery of motion. With the injured finger at rest, pain subsides and the other fingers are free to move. If the injured finger is not immobilized, it is painful and causes inhibition of motion of the other fingers which subsequently might become stiff because of the lack of active use.

The practice of immobilizing a finger in the straight position on a flat strip of metal or wooden tongue blade is dangerous, because capsular contraction and dense adhesion formation might occur. This is particularly true at the metacarpal phalangeal joint. A fracture of the phalanx held in the straight position usually increases displacement of the fracture. Further, the other uninjured fingers then cannot move freely in flexion. Active exercises of the uninjured fingers must be carried out, accomplishing full extension and full flexion. The patient must cooperate in these exercises and regain use of the finger with his own power. Passive exercises of

the fingers are to be avoided. If a joint that is tending to become stiff is treated with passive exercises, it likely will tend to become even more stiff because of increase in traumatic exudation with subsequent adhesion formation. Fractures in the hand and fingers should be reduced as accurately as possible. This is particularly true in fractures of the phalanges. Inadequate reduction of fractured phalanges will hinder free movement of the flexor tendons. Fractures of the phalanges usually have forward angulation and, if this is not corrected, there will be a corresponding limitation of motion of flexion due to bony prominence which sometimes will cause permanent stiffness. This is especially true where there is subluxation of a joint that remains uncorrected. The danger of redisplacement of fractures, dislocations or subluxations must be recognized and corrected immediately.

In compound injuries of the fingers, immediate operation must be carried out with thorough debridement of the devitalized soft tissue. Viable skin flaps are replaced and sutured without tension. If there is any question of swelling of the finger, it is better to maintain apposition of the skin edges by bandaging alone. The finger is not constructed to allow for a great deal of post-traumatic swelling. Severed tendons should be sutured if there is no danger of infection. If there is any question, tendon repair can be carried out at a later date after the wounds have healed. It is advisable not to use catgut, since it may act as a foreign body. In an adult where a finger is severely crushed and injured and permanent stiffness appears likely, early amputation is advisable, as this allows for active mobilization of the remaining fingers. In a child where there is more power of regeneration, conservative therapy of a badly traumatized or injured finger is sometimes justified. At no time should a thumb be amputated; it is much better to have a stiff

Presented at the Center for Continuation Study, University of Minnesota, November 21, 1956.

Dr. Nydahl is Clinical Associate Professor, Division of Orthopedic Surgery, University of Minnesota.

thumb against which the fingers can oppose and carry out the grasping function of the hand. Any kind of a thumb, even though it is stiff, is better than no thumb at all. If there has been severe trauma to the skin, one can treat the thumb by the Orr method of immobilization in a plaster dressing with the thumb held in the opposed position. Later, when healthy granulation tissue has developed, skin grafting can be carried out. Another method which can be utilized is that of burying the thumb in a skin flap of the abdomen. The one objection to this is that it does hinder the mobilization of the fingers. In one case that I am aware of, the thumb had been completely severed at the metacarpal phalangeal joint. It was brought in along with the patient. The plastic surgeon* placed it in the abdomen and later transferred it by skin graft and fusion to the distal thumb metacarpal and the patient now is most fortunate and pleased to have a thumb even though stiff. For cosmetic reasons he is most appreciative.

Fractures of the Shafts of the Metacarpals

Care should be taken to avoid excessive immobilization of these fractures. The fingers should be left free so that, no matter what type of bandage or splinting is utilized, active use of the fingers and thumb can be carried out. As in the case of the ribs which are anchored by the intercostal muscles, the shafts of the metacarpals are anchored by the fascia and interosseous muscles. Consequently, very little displacement is apt to occur. Spiral fractures of the shafts of the metacarpal usually can be treated with a dorsal plaster dressing running from the metacarpal phalangeal joints to the upper forearm with the hand firmly strapped. Occasionally, difficulty is encountered in transverse fractures of the metacarpal bones with marked displacement, especially in the case of the index and little fingers. Sustained traction plus volarward pressure on the distal fragment usually will overcome the overriding and backward angulation. If this does not permit satisfactory reduction, one should then carry out an open reduction and impact the fracture fragments. If necessary, internal fixation with an intramedullary Kirschner wire or cross fixation into adjacent metacarpals can be utilized.

*Grotting, John: Personal communication.

Fractures of the Neck of the Metacarpals

This fracture which is frequently termed "Saturday night fracture" is a common fracture and occurs most frequently in the little finger metacarpal bone and to a lesser extent in the index finger metacarpal bone. If satisfactory reduction is not accomplished, rather serious disability may occur. It is a mistake to treat this fracture with the finger in the straight or hyperextended position, as this will tend to increase the forward tilt of the head of the metacarpal towards the palm. Further, in these positions the capsule and lateral ligaments are relaxed, inviting contracture and serious stiffness. The fracture is reduced by flexing the metacarpal phalangeal joint and the proximal interphalangeal joint to a right angle, and, with the middle finger holding the proximal fragment, pressure is applied with the thumb on the flexed proximal interphalangeal joint in the backward direction. Then a posterior plaster dressing is applied from the upper forearm to the fracture site, while reduction is being maintained as outlined above. Next, a narrow plaster splint is applied from the tip of the finger over the extensor surface of the finger joining the splint. Care should be taken to place adequate padding over the proximal interphalangeal joint so as to avoid excessive pressure, which sometimes can result in pressure necrosis of the skin and subcutaneous tissue. Immobilization is carried out for a period of three weeks. During this time the other fingers and thumb are free to carry out active exercises. An alternative method would be to run an intramedullary Kirschner wire through the distal fragment into the proximal fragment after this fracture has been reduced. This method even allows for some motion of the involved finger in addition to the other fingers. This wire is removed after three weeks. In regaining motion, passive stretching should be avoided.

Fractures of the Phalanges

These fractures occur frequently and most commonly in the proximal phalanx. The typical displacement is that of anterior angulation due to the pull of the lumbrical and interosseous muscles which run from the flexor side of the metacarpals to the extensor aspect of the proximal phalanx distally, thus causing flexion of the proximal fragment and extension of the distal fragment. In order to obtain reduction, the finger

is put up in the flexed position. This can be done over a one-inch gauze roll held with adhesive strapping or by utilizing a malleable splint reinforced with a forearm plaster dressing. Or the finger can be immobilized in the flexed position with a carefully molded finger plaster dressing. These dressings have to be watched carefully for any possible loosening with resultant slipping of the fracture fragments. Unstable fractures of the phalanges or unstable fractures involving a joint should be treated with the finger in the flexed position, utilizing pulp traction or skeletal traction to the distal phalanx carried to the volar aspect of the wrist incorporated in a short arm plaster dressing. In lining up the finger, rotational deformity can be avoided if the tip of the finger points toward the tubercle of the navicular bone (toward the base of the thenar eminence).

Sprains

Sprains of a metacarpal phalangeal joint or interphalangeal joint can cause a great deal of concern and sometimes will give symptoms over a long period of time. The involved joint is painful and swollen. X-rays may show small chip fractures. Sometimes an actual dislocation at the time of the injury occurs, with spontaneous reduction and tear of the lateral ligaments and of the capsule. The involved joint should be immobilized for two weeks with firm adhesive strapping or collodion gauze dressing. The patient should be warned that persistent swelling and stiffness of the joint may last for several weeks. Active exercises are utilized in regaining motion. During the period of immobilization the involved joint is bandaged in slight flexion.

Dislocations

Dislocation of a metacarpal phalangeal joint or of an interphalangeal joint usually results from hyperextension of the phalanx and strain causes it to displace backwards. Reduction usually can be accomplished by traction followed by flexion. In some cases, reduction is not accomplished by closed manipulation. This is because the head of the metacarpal becomes buttonholed through a vertical slit in the capsule which closes in on the neck of the bone. One should not hesitate to carry out an open reduction through a lateral incision. The flexor tendons are retracted, the tight bands of capsule are divided, and the dislocated phalanx is pushed forward into its nor-

mal position. In both closed and operative reduction, the involved finger is immobilized for three weeks in the flexed position.

Drop Finger or Mallet Finger

This subcutaneous tendon injury resulting in avulsion of the extensor tendon at its insertion in the terminal phalanx is commonly called "baseball finger" because of its frequent occurrence among baseball players. Power of extension over the distal joint is lost. The injury occurs while the extensor tendon is actively contracting and the finger at the distal joint is forcibly flexed. A secondary deformity may occur with hyperextension at the mid joint. The extensor tendon has two lateral slips which form over the basal phalanx and terminate at the distal joint. A central slip of the extensor tendon inserts at the proximal portion of the mid phalanx and extends the mid joint. With avulsion of the extensor tendon at the terminal joint, the extensor tendon retracts and increases the power of the central slip to extend the mid joint, resulting in hyperextension of this joint. The principle of treatment is the same whether the tendon alone has avulsed, whether it has avulsed along with a fragment of bone or, in children, avulsed along with the epiphysis at the base of the phalanx. It is that of hyperextending the distal joint and flexing the mid joint which allows for reapproximation of the avulsed tendon to its normal site of insertion. With the finger held in this position, a well-molded plaster dressing or malleable metal splint is applied. Continued immobilization should be carried out for six to eight weeks in recent cases. In old cases of several weeks' duration, the same treatment should be carried out, but immobilization should be continued for eight to ten weeks. Operative repair of this injury can be carried out, but conservative therapy is the procedure of choice. The danger of breaking down of the skin and development of a possible draining sinus, because of the superficial location of the tendon, should be recognized. If surgery is performed, the method of repairing the tendon with removable stainless steel wire after the method of Bunnell has merit.

Fractures at Base of Thumb Metacarpal

Fractures at the base of the thumb metacarpal are of two types: (1) Fracture not involving the joint, and (2) Fracture involving the joint with

an actual fracture dislocation (Bennett's fracture dislocation).

These fractures usually occur from a force on the radial side of the metacarpal, forcing it across the palm of the hand, resulting in outward angulation and prominence of the thumb metacarpal at its base. In fractures that do not involve the joint, the fracture is reduced by grasping the neck and the head region of the thumb metacarpal and pulling it backward and outward, while at the same time pressing firmly over the base of the metacarpal with the thumb of the other hand. Then, with the thumb metacarpal held in this position, a short arm plaster dressing is applied incorporating the thumb metacarpal and the proximal phalanx held in the slightly flexed position. Immobilization is carried out for a period of four weeks.

Bennett's fracture dislocation is more serious and the treatment is more complicated. The articular surface of the greater multangular bone is saddle shaped. The base of the fractured thumb metacarpal dislocates proximally with a smaller triangular fragment remaining in its normal position. This fracture dislocation is unstable and reduction is accomplished by traction in abduction on the extended thumb with pressure applied at the basal portion of the thumb metacarpal. Reduction is then maintained by pulp traction or skeletal traction to the distal phalanx of the thumb with a banjo type of splint incorporated in the short arm plaster dressing. Collodion gauze dressing encircling two narrow strips of skin extension tape can also be used. Traction should be continued for a period of four weeks and then discontinued and immobilization in the plaster dressing carried out for another

two weeks to allow for solidification of the fracture.

Dislocations of Carpal Metacarpal Joints

All four finger metacarpal bones can be dislocated posteriorly. Manipulative reduction should be carried out as soon as possible and immobilization carried out for three weeks in a dorsal plaster dressing. Occasionally, only one or two of the metacarpals are dislocated, and closed manipulative reduction should be carried out. Sometimes this is difficult but, fortunately, the bony thickening does not cause too great a disability as far as the function of the hand is concerned. Occasionally, a metacarpal may be markedly displaced either posteriorly or into the palm of the hand and, if closed manipulative reduction is not successful, open reduction should then be carried out. Reduction is maintained by a posterior plaster dressing alone or by the additional insurance of transfixion of the base of the metacarpal into the corresponding carpal bone with a Kirschner wire which is removed after three to four weeks.

Chip Fractures Involving Joints

Where a chip fracture of any size has resulted in marked rotation of the fracture fragment and closed manipulation is not successful, the fracture fragment should be replaced by open reduction. Occasionally, particularly in old cases, the bone fragment should be removed. Very small bone fragments usually do not cause any real trouble. The joints should be immobilized for seven to ten days before active exercises are started.

"O" TYPE MOTHERS LESS FERTILE

Blood group O mothers appear to have a lowered reproductivity as compared with mothers of other blood groups, reports Dr. Warren H. Pearse of the Department of Obstetrics and Gynecology, University of Michigan.

For some years, an apparent differential fertility has been suggested where mother and father belonged to different blood groups. An analysis of some 26,000 deliveries in Australia showed that group A women had a higher average number of pregnancies than did group O women. "The deficiency of group A (and apparently group B) children born to group O mothers

was not present in the first pregnancy, was present in the second and was greatest in third-born children. These findings may suggest some type of immunization mechanism," Dr. Pearse said.

"While there are conflicting reports, it seems definite that the ABO blood groups do result in a selective loss of incompatible children, and that there is a gradual reduction of fertility, or perhaps reproductivity, due to this selection."—PEARSE, W. H.: ABO blood groups in obstetrics, *American Journal of Obstetrics and Gynecology*, 74:538 (Sept.) 1957.

Renal Trauma

C. D. CREEVY, M.D.

Minneapolis, Minnesota

INJURIES of the kidney are surprisingly rare considering the variety of violence to which modern man is exposed by the automobile, the tractor, the airplane, and by heavy industry. In 1941 Campbell found that renal trauma was responsible for but one in three thousand surgical admissions to Bellevue Hospital, which receives a large number of accident victims. Similarly, Nelson observed in 1948 that it caused but 0.03 per cent of 150,000 surgical admissions to the London Hospital. Guterbach estimated that the kidneys were injured in only 10 per cent of the victims of fatal violence.

The protected location of the kidneys undoubtedly accounts for their relative impregnability, since their consistency is such as to permit shattering by comparatively minor blows. They are protected behind by the spine and its muscles, as well as by the ribs, which also shield them to some extent laterally and in front, where the abdominal wall, perirenal fat, and intestines serve to cushion impacts. The loose attachments of the kidneys permit them a limited retreat from blunt forces. The kidneys of children are somewhat more vulnerable than those of adults because of their lower position and the scarcity of perirenal fat, and it is well established that large or distended organs are more easily injured than are normal ones.

The kidneys may be injured by a variety of forces, such as blows with blunt objects, falls (including those upon the feet and buttocks), crushing injuries (automobile wheels), and violent flexion or twisting. In addition, the literature contains a fair number of instances of spontaneous renal injuries, even in the absence of demonstrable antecedent disease. Penetrating wounds (missiles and knives) are quite uncommon in civil life, and are usually associated with injuries to other viscera which overshadow the renal lesions.

Changes in the kidney vary from laceration

Presented at the Center for Continuation Study, University of Minnesota, April 7, 1956.

of a capsular vessel with a small perirenal hematoma to shattering or pulpification of the whole organ, with or without avulsion of its vascular pedicle. Late effects include necrosis of devascularized fragments with consequent secondary hemorrhage, infections in or about the kidney, urinary extravasation, and late fibrosis which may compress the kidney itself or the upper ureter.

At the Los Angeles General Hospital, which has an active emergency service, there were 220 renal injuries between 1934 and 1950. Eighty-four were classified as contusions, seventy-eight as lacerations, and twenty-two resulted from shootings or stabbings. In addition there were thirty-six which were incidental to extensive skeletal or visceral traumas.

It suffices to classify renal injuries rather simply as contusions (which include perirenal hematomata), and lacerations (which include rupture of the organ and avulsion of its vessels). Injuries to the renal pelvis and ureter will be discussed separately.

Contusion and Perirenal Hematoma

When contusions occur, there is pain in the flank with tender fullness, bulging, or a palpable mass in the region of the kidney. Spasm of the psoas muscle is common, and signs of anemia, hemorrhage, and shock vary with the amount and rate of bleeding. The urine is ordinarily clear but contains microscopic blood, although gross hematuria occurs with more serious damage. Roentgenography shows blurring or absence of the lateral margin of the psoas with, in larger hematomas, enlargement of the renal shadow. Curvature of the spine with its concavity toward the affected side may or may not appear, and elevation of the hemidiaphragm may be found. Excretory urography discloses a normally functioning and appearing kidney, although the collecting system may appear compressed; extravasation of contrast agent is uncommon. If contusion is extensive, function on the affected side may be absent, only to return later. A urogram should always be made so that the condition of

the opposite kidney will be known should operation become necessary.

At a variable time after injury there may be ecchymosis in Petit's triangle or in the groin. In other words, there is a history of injury with some evidence of internal bleeding, and clinical and radiologic evidence of a perirenal accumulation of fluid without the toxemia which accompanies perinephritic abscess.

Treatment begins with bed rest and close observations of the pulse, blood pressure, urine, local swelling, and hemoglobin. Conservative treatment with primary reliance upon transfusion is indicated unless bleeding gets out of hand, because bruises cannot be repaired surgically, and operation is likely to lead to removal of a potentially useful kidney. Because organisms may reach the traumatized tissue via the blood stream, a wide spectrum antibiotic should be given. A hematoma or perinephritic abscess may require later evacuation.

Subsidence of signs and symptoms should not lead to resumption of activity for two or, preferably, three weeks because of the danger of severe secondary bleeding.

If profuse hematuria persists despite repeated transfusions, surgical exploration is required. A conventional lumbar incision is indicated unless there is evidence of an intraperitoneal lesion. A large quantity of matched blood should be instantly available. Scholl has maintained that operation is easier and safer if a number of days has elapsed since injury, because much bleeding will have stopped spontaneously and the tissues will be less friable. Devitalized renal fragments may be removed, arterial bleeders ligated, and venous bleeding controlled by compression with ribbon catgut passed through "belt loops" made in the renal capsule. This should be tied just tight enough to stop the bleeding without strangling the renal substance. If the capsule has been stripped off by the bleeding, recourse may be had to packing with absorbable hemostatic agents or gauze. This may be inserted over a sheet of rubber dam to facilitate easy removal. If the kidney has to be removed and the capsule has been stripped off so as to conceal the renal vessels, it may be incised circularly around the hilus and the pedicle easily found. Scott's maneuver of compressing the aorta with a stick sponge may be invaluable in the presence of brisk arterial bleeding.

A patient treated successfully by conservative methods, either surgical or medical, should be kept under observation for a considerable time after recovery. Followup should include excretory urography to detect hydronephrosis from ureteral compression by late scarring, urinalysis to uncover silent infection, and repeated measurement of the blood pressure, because perirenal fibrosis may occasionally produce hypertension through compression of the parenchyma. These complications are not common enough to be used as arguments for nephrectomy at the time of injury, because a slightly crippled kidney is better than none, especially in a young person. Priestley has found that about 25 per cent of patients treated conservatively will be left with some disorder of the kidney.

Laceration of the Kidney

Obviously, laceration of the kidney differs from the foregoing only in degree: bleeding is more severe, blood pressure is harder to maintain, and local findings are more conspicuous. Since this represents a more severe trauma, associated extrarenal injuries are more common. Thus preliminary studies should include a film of the abdomen made in the upright position, if feasible, in order to detect free gas under the diaphragm. While the injured kidney may not be visualized by excretory urography, it should be employed if only to make sure that the other organ is competent to support life. If it is desired to delineate the affected kidney, retrograde pyelography properly done is innocuous, and will show extravasation.

The general principles of treatment have already been outlined. Because of the more extensive character of the injury there is more likely to be extravasation of urine or perinephritic abscess or both, and operation is more likely to be necessary. One may safely say, however, that the majority of renal injuries will heal with good conservative management. Of the 220 cases from the Los Angeles General Hospital already mentioned, only twenty came to operation, with one death. Many of the others who died were in the group with extensive extrarenal injuries, so that the renal injury did not play a significant part in the fatal outcome.

Injuries of the Renal Pelvis and Ureter

These structures are ordinarily protected from blunt trauma by their flexibility, mobility, and loose attachments; even penetrating lesions are

rare, coming more often from ureteral catheters and surgical instruments than from external violence. Symptoms depend upon the level and character of the injury, and consist usually of bleeding, followed by signs of urinary extravasation, and, if unrecognized, by infection and toxemia. Bleeding may be absent if the excretory channel is torn off.

If such a lesion is suspected but not shown in the excretory urogram, a retrograde pyeloureterogram will demonstrate it. If a laceration is found and a catheter can be passed to the renal pelvis, it should be secured in place and antibiotics administered. If clinical signs of extravasation appear, extraperitoneal drainage will be required.

A severed ureter requires repair. Ragged edges are trimmed off and a small Robinson catheter with extra eyes at the renal end is inserted through a perforation just below the injury and passed to the renal pelvis. A simple end-to-end anastomosis is made with fine chromic catgut (nonabsorbable sutures will become encrusted), which is also used to secure the catheter to the ureteral adventitia.

The ureters may be injured either surgically or cystoscopically. A catheter may be pushed through the ureteral wall in the presence of an ureteral stone or other obstruction. If the urine is sterile and the perforation is below the obstruction, no harm usually results. If virulent organisms are present, or if the hole is above the obstruction, relief of the latter and external drainage are essential. If local or general conditions prevent a definitive operation, nephrostomy may save the kidney, but should be supplemented by local drainage, correction of the obstruction being done later.

One or both ureters may be crushed, perforated, divided, or ligated during difficult pelvic or lower abdominal operations, usually as a result of clamping, sewing, or cutting in a pool of blood. If the injury is recognized at the time, ties and stitches should be removed from the area; if the ureter has been crushed, the damaged tissue should be removed and an end-to-end anastomosis made as previously described. Simple division is similarly treated but without removal of tissue. A small perforation (needle) can be covered with a flap of adjacent peritoneum (serous side down) without drainage. The localization of injury may be facilitated by the insertion of ureteral catheters through a cystoscope during operation.

Symptoms and findings of ureteral occlusion not recognized at the time depend upon the level and character of the damage, as well as upon whether one or both ducts have been injured. Bilateral occlusion causes anuria; urine leaking into the peritoneum produces peritoneal irritation and later demonstrable free fluid; if damage is bilateral, uremia will occur. An intraperitoneal leak can be demonstrated by excretory urography done before renal function has been suppressed. Any of these situations requires cystoscopy and ureteral catheterization to disclose the level of obstruction. Occasionally, this will be due to simple kinking of the ureter by an adjacent ligature. If a catheter can be passed to the renal pelvis, a Foley catheter should be inserted into the bladder and the former tied to it. They should be left *in situ* for some time. Usually, however, bilateral obstruction will prove to be complete and will require surgical correction. If the general state is good, the incision should be reopened and the offending ligatures removed or the necessary repairs made as already outlined. If it is poor, unilateral nephrostomy is made and the ureters repaired later. Rarely after nephrostomy, an obstructing tie will be absorbed so that no further treatment will be necessary.

Unilateral injury may be silent or cause chills, fever, or renal pain. If the opposite kidney is normal, unilateral ligation will not be reflected in the urinary output. Sometimes it will first be suspected after an extravasation has ruptured externally, resulting in an urinary fistula. This is readily identified; the ureterovaginal fistula is readily distinguished from the vesicovaginal variety by the fact that colored fluid injected into the bladder will not enter the vagina in the former.

The occurrence of an urinary fistula necessitates ureteral catheterization. Obstruction is found on the side and at the level of the fistula. In the unlikely event that the catheter on the affected side will pass to the kidney, it should be left inlying for some time in the hope that the fistula will close.

If obstruction is complete, surgical correction is needed. If the patient is elderly with a normal opposite kidney, nephrectomy is the simplest solution. In younger patients and in older ones with abnormal opposite kidneys, surgical repair of the

Tracheotomy in the Acutely Injured Patient

ROBERT E. PRIEST, M.D.

Minneapolis, Minnesota

RECENTLY trauma to the head, face, neck and chest has provided many indications for tracheotomy. In times past, most tracheotomies were done to relieve obstruction of the airway caused by inflammatory conditions or neoplasms. Acute injuries of rather severe degree are becoming more common in our modern civilization with its rapid transportation.¹⁻³

Tracheotomy is a useful procedure in head injuries with cerebral concussion, even though the face and neck are not injured. In the unconscious patient the jaw relaxes, the tongue falls back into the throat, and evacuation of secretion from the pharynx by voluntary means under control of the patient ceases. Pooling of secretion in the pharynx may occur and aspiration of this secretion may follow. Aspiration of vomitus is not uncommon. The use of feeding tubes produces irritation of the pharynx and causes more secretion to be formed in the pharynx. Cough reflex is at a minimum of efficiency. The use of tracheotomy to permit frequent and adequate cleansing of the lower respiratory tree has grown steadily in recent years. Similar indications exist in barbiturate and other poisonings.

Jaw fractures, injuries to the front of the neck with edema of the pharynx, and fracture and edema of the larynx make it necessary to provide an airway by opening the trachea below the point of injury; inability of the patient to clear his own airway may occur in these conditions, as well as in cerebral concussion or poisoning.

Tracheotomy in burns may be necessary because of aspiration of hot gases which cause edema of the larynx. In World War II, it was found that aviators who were apparently in good condition when rescued from burning aircraft sometimes died unless "prophylactic" tracheotomy was per-

formed; secondary swelling of the laryngeal interior occurred, and the patient died of asphyxia even though all other potential causes for death were under control.

During the past few years, the use of tracheotomy in the treatment of chest injuries has become more and more widespread.⁴⁻⁶ The purpose of tracheotomy in chest injury is twofold. Cleansing the lower respiratory tree by suction through the tracheotomy probably is the most important reason for doing tracheotomy in chest injuries. A second indication occurs in the so-called "flail chest." Here a large segment of the chest wall "floats" and there is paradoxical motion on respiration. When the patient breathes in, the flail segment of the chest goes in instead of out, because it is no longer anchored to the rest of the chest wall.

It has been shown by several authors that patients with flail chests do better with tracheotomies, because the total volume of air moved during the respiratory act is reduced. Resistance of air coming in through the tracheotomy is less than through the nose and pharynx. Experimental work measuring pressures in the pleural spaces before and after tracheotomy in humans and in dogs has shown a definite advantage in the case of tracheotomy.

Positive pressure can be applied during the inspiratory phase of respiration to provide stabilization, or at least partial stabilization, of the flail segment of the chest. This reduces pain and also increases respiratory efficiency.

Wounds of the larynx, fractures of the larynx, fractures of the trachea constitute indications for tracheotomy. Perhaps the first case of tracheotomy in trauma reported was that of Habicot who wrote in 1620 A.D. He recounted the case of a boy wounded and left for dead. He opened the boy's trachea and removed a laryngeal blood clot. Habicot had two other successful cases, one was an officer with a cut throat, and the other was a young woman with a gunshot wound of her

Dr. Priest is Clinical Associate Professor of Otolaryngology in the University of Minnesota Medical School, and Senior Consultant in Otolaryngology at Minneapolis General Hospital.

This paper was presented at The Center for Continuation Study April 6, 1956, as part of a Symposium on Trauma.

throat. In 1714, Detharding recommended that the operation be done on persons apparently drowned. This recommendation was later reiterated by Heister (1739) and de Pouteau (1783) in order that all water might be got out of the lungs through a tube.⁷

A most interesting case report, for an indication which will not be met in normal life, is as follows: A London surgeon named Chovell persuaded a condemned man named Gordon to allow him, for a substantial fee, to perform a tracheotomy upon Gordon the night before his execution by hanging was scheduled. The surgeon reasoned that the rope would go around the condemned man's neck above the point where the trachea would be opened. The condemned man was to hang for a certain number of minutes and then be cut down. If he could survive the hanging, he had satisfied the law's requirement that he be punished. The surgeon had tried the experiment on several dogs always with success. But his human subject, although still alive when cut down by his friends after the hanging, succumbed very soon.

Tracheotomy can be done under emergency conditions or can be done in orderly fashion. It is possible to convert emergency conditions into orderly conditions by introducing an airway through the larynx when this is possible.

Laryngotomy or intercricothyrotomy consists of making a horizontal incision through the cricothyroid membrane and holding the opening patent by some temporary type of retractor until a real tracheotomy can be done. Intracricothyrotomy should always be a temporary procedure. If it is not, damage to the voice will occur.

Emergency tracheotomy is done, according to the technique of Chevalier Jackson as follows: The surgeon stands on the patient's right and with his left hand sweeps the soft tissues away from the midline by pushing his thumb and middle finger from the midline laterally. He makes a vertical incision in the midline following the knife with his index finger down the front of the larynx and trachea. He feels the cricoid cartilage, then the tracheal rings and guides the knife blade through the tracheal rings and holds his finger there until something can be put into the trachea to hold it open. Naturally, there is profuse bleeding and the procedure must be revised as soon as orderly conditions occur.

Orderly, or tranquil, tracheotomy is done when an airway can be provided. The introduction of a bronchoscope, an anesthetic endotracheal tube, or a Mosher lifesaving tube, through the larynx provides the patient with an airway and permits orderly tracheotomy to be done. It may be done under local or general anesthesia depending upon the conditions. Infiltration with one per cent procaine is satisfactory. One can make a midline incision or a "collar" incision. In small children, there is more danger of skeletonizing the trachea too much with a collar incision. In adults, the contraindications to a collar incision are much less valid than they are in children.⁸

The skin and superficial fascia are incised and veins are secured and ligated. The deep fascia is incised until the thyroid isthmus is encountered. The thyroid isthmus may be cut in the midline or retracted. We generally cut it in the midline. The cricoid and trachea are identified and the tracheotomy incision is made through the second or third tracheal rings and a "button" of tracheal wall is removed. This does no harm to the trachea on a permanent basis and makes changing of the tube much less dangerous than when a "slit" incision is made in the tracheal wall. A tracheotomy tube of proper size is inserted and the wound is not closed; this helps to prevent emphysema of the soft tissues of the neck and head.

Errors and accidents accompanying tracheotomy.—Too short an incision prolongs the operation and makes it more difficult; after incision of the skin and superficial fascia, the next layer may not be separated in the midline and the operator may become disoriented; the dome of the pleura may be punctured as it bulges up into the wound and pneumothorax may be induced. The knife used to incise the trachea may be carried through the posterior wall of the trachea into the esophagus. The cannula may fail to enter the tracheal lumen and may make a false passage outside of the trachea. The operator may fail to identify the cricoid cartilage and open the larynx instead of the trachea; this results in difficult decannulation and damages the voice very markedly. Entrance of blood into the trachea can be prevented by proper hemostasis unless there is very urgent need for opening the trachea. It should be sucked out carefully when conditions are orderly and will be coughed out by the patient unless

he is unconscious when emergency tracheotomy is carried out.

Postoperative complications include emphysema of the subcutaneous and fascial layers of the neck. This is usually not serious. Emphysema of the mediastinum occurs in many cases of tracheotomy and is not particularly important unless pneumothorax occurs with it. Pneumothorax, which sometimes occurs, may be fatal if it is bilateral. If there is a "tension pneumothorax," the condition may have to be relieved by endothoracic suction. Blood in the mediastinum was found at autopsy in one of our cases, although it did not appear to be the cause of death. Laryngeal or tracheal stenosis should not follow a properly done tracheotomy. Wound infections are rare, particularly since antibiotic therapy has been available. Tracheitis usually follows tracheotomy but is transitory.

Decannulation is carried out after the tube has been plugged by a rubber stopper for twenty-four to forty-eight hours. If the tracheotomy has been

properly performed, decannulation should not be difficult.

RENAL TRAUMA

(Continued from Page 855)

fistula is indicated. If the fistula is close to the bladder, ureteral reimplantation is preferred. If the opening is too high for this, and especially if the ureter distal to it has been destroyed, some form of ureteral substitution is needed. Defects extending as high as the brim of the pelvis can be replaced with tubular flaps fashioned from the bladder (Boari). A two-stage procedure is required to replace both pelvic ureters by this method. Anastomosis to the ureter must be meticulously accurate, and a catheter must traverse the new and old ureters so that the eyes of the catheter lie in the renal pelvis, lest urine pass down along-side it and burst suture lines with recurrence of the fistulae.

When the defect is too long for this method, one may isolate a loop of distal ileum, make an enteroanastomosis around it, close both ends of

the loop, and implant both ureters into it (Longuet, Pyrah). The middle of the loop is widely joined to the bladder. For unilateral defects a shorter loop is closed at one end and joined to the bladder at the other, the ureteral stump being implanted near the upper end. If necessary, the whole ureter can be replaced in this manner (Annis).

Very occasionally, as Millin has pointed out, anuria following pelvic operations may result from compression of the ureters by a pelvic hematoma. In such cases, ureteral catheters pass without difficulty and free diuresis ensues as long as they are present. Such an hematoma may require evacuation.

Periodic ureteral dilatations should be carried out at increasingly longer intervals after any ureteral injury in order to detect and dilate strictures.

Successful Expulsion of Tapeworms

JOHN H. THOMPSON, JR., Ph.D.

Rochester, Minnesota

QUESTIONS frequently are directed to parasitology laboratories relative to the therapeutic expulsion of tapeworms, and reports of repeated failures to accomplish this have been received. The primary objective in the care of a patient harboring a tapeworm is the recovery and identification of the head of the worm. Failure to accomplish this means inability to determine the results of the treatment. This is true whether the parasite be *Taenia solium* (pork), *T. saginata* (beef), *Diphyllobothrium latum* (fish), or one of the smaller forms, such as *Hymenolepis nana* or *H. diminuta* (cereals). Immediate riddance of these worms is a major concern for patients who know they are harboring them.

In the case of *T. solium*, which is rare in the United States, there is further concern beyond that of the esthetic considerations because of the danger in the continued presence of this parasite in the intestine. The eggs of *T. solium* are able to hatch in the intestine of the human host; the larval stage (onchosphere) then pierces the intestinal wall, is carried by the blood to various sites, such as the brain, and produces cysticercosis not unlike that seen in the hog, which serves as the intermediate host.

Cysticercosis is difficult to treat and may prove fatal. Thus, the person known to be harboring the adult pork tapeworm should be freed of the parasite as quickly as possible. The head of the worm should be recovered and identified, after which the patient need have no further concern beyond avoidance of the repetition of infection. However, if the head is not recovered, a needless period of doubt and delay ensues with the serious potential consequences already mentioned. The term "needless" is used advisedly, since there is, and has been for some time, available a method of treatment that, when conducted properly, will assure success.

From the Section of Clinical Pathology, Mayo Clinic.

This is the thirty-eighth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

This method was described in 1927 by Magath and Brown.¹ It involves three essential steps, namely (1) preparation of the patient, (2) administration of the anthelmintic and (3) the search for and recovery of the head. The first step requires the patient to forego lunch and supper on the day prior to treatment, although coffee, tea or water may be taken freely. The evening prior to treatment, the patient takes 15 to 30 gm. of magnesium sulfate, and the same dose is taken again early the next morning. No breakfast is given. After a bowel movement, the patient is given 30 ml. of the following emulsion: oleoresin of aspidium, 6 gm.; powdered acacia, 8 gm.; distilled water to make 60 ml. One hour after administration of the first 30 ml. of this emulsion, the second 30 ml. is given. Two hours after the second dose of emulsion, 30 gm. of magnesium sulfate is given, followed two hours later by a large soapsuds enema. For children, and for adults who cannot tolerate the treatment by mouth, it is preferable to administer the materials through a gastric tube. The amounts of magnesium sulfate and oleoresin of aspidium should be reduced by half for children.

The method of collection of stools requires emphasis. This part of the procedure is critical, and it demands absolute attention to details and strict supervision by the physician or those assisting in the procedure. Stools passed prior to administration of the aspidium should be collected in one container and kept separate from those collected in a second container, which is designated "following aspidium." It is imperative to have available large receptacles that the patient may use directly; stools should not be collected in vessels to be transferred to other containers. Strict supervision of the patient is required so that no toilet paper or other material be allowed in the containers. The patient should not use a flush toilet. The search for and recovery of the head of the worm should follow immediately after passage of stools following the enema.

When the procedure has been carried out as just outlined, the receptacle used after treatment will contain several quarts of water, shreds of mucus and the tapeworm. The water is decanted carefully through a large (at least 12 cm. in diameter) 20-mesh sieve. Warm water is then run gently through the sieve to remove debris, leaving only the tapeworm. The contents of the sieve then are emptied into a black enamel pan measuring about 25 by 30 cm. The inverted sieve is rinsed out thoroughly with warm water into the pan so that nothing remains on the meshes. The search for and positive identification of the head of the worm are done by examining the entire specimen and any portions broken from it.

One often recovers a complete and intact specimen from terminal segments to head. However, owing to mechanical injury in passage and the active peristalsis resulting from the treatment, one sometimes recovers specimens that are broken in several places. The head may be present in the washings but may be broken off so near the first segment that extreme care in the search is required. It is also for this reason that no food particles or toilet paper be in the recovered material. I have been confronted on occasions with the presence of food particles and by diligent searching and good fortune have found the head inside the undigested shell of a kernel of corn or a pea; once it was found adhering to a small clump of disintegrated toilet paper that was among several pieces in the container.

If the head is not recovered, the success of the treatment remains in doubt, as already mentioned. Then a period of approximately twelve weeks must

follow in order to allow segments to develop and appear in the stools, which will occur if the head has not been expelled.

During the thirty years following publication of this standardized treatment for tapeworms, many patients infested with these parasites have come to this laboratory. In most instances, they have told of previous repeatedly unsuccessful courses of treatment involving a variety of drugs and techniques. The method just outlined has resulted in no failures to date in all patients on whom the procedure has been carried out with precision and with attention to details.

Without trying to evaluate other methods currently advocated in the literature, I should like to mention three trials in which quinacrine hydrochloride (atabrine) was substituted for emulsion of aspidium. Two were attempts to eradicate *T. saginata* and one was an attempt to expel *D. latum*. Results of all three trials were unsatisfactory. Portions of the worms were recovered, but the head was absent from the collected material. In each of these three instances, when the patients returned for a second course of treatment, oleoresin of aspidium was used and the entire worm and its head were expelled. This time-proved method of Magath and Brown is recommended to those who have difficulties in effecting expulsion of entire tapeworms and recovery of the all-important head.

IMPORTANCE OF X-RAY IN APPENDIX CONDITION

X-ray examination can be the basis for life-saving surgical removal of appendiceal coproliths, even when the physical examination and symptoms fail to present a clear cause for abdominal pain.

This is the report of two radiologists from Bismarck, N. D., Drs. R. M. Berg and H. Milton Berg, who reported their experience with the coproliths in the June, 1957, issue of *Radiology*.

Sometimes a patient's symptoms are not characteristic of the presence of the coproliths, which cause the appendicitis, the Bismarck physicians pointed out.

"A review of thirty-five patients with the condition reveals that 50 per cent would not have had sufficient evidence, without x-ray findings, for surgical explora-

tion, despite the history, physical and laboratory examinations. In four patients, the physical examination was entirely normal, although acute symptoms were present," they added.

Other conclusions in their report:

—The correct diagnosis can frequently be achieved only by x-ray examination of the abdomen. Other findings were insufficient to justify a diagnosis of appendicitis in half of the patients.

—There is a 90 per cent chance that a patient with the coproliths has an acute appendicitis; there is a 48 per cent chance that the appendix is gangrenous or perforated.

Spontaneous Pneumothorax

COLEMAN J. CONNOLLY, M.D.

Saint Paul, Minnesota

THE PROBLEM of spontaneous pneumothorax is one which deserves serious attention by the physician because of the urgency of a tension pneumothorax with mediastinal displacement or a bilateral pneumothorax. Death may result from either of these latter circumstances.

Because of this the physician should be in complete control of the situation at all times, and this control can best be obtained by surgical excision of ruptured blebs or bullae, usually located on the apex of the lung. When a bilateral pneumothorax is encountered, one can do a simultaneous, bilateral thoracotomy through a transverse, transternal incision in the 4th intercostal spaces anteriorly with astonishingly low morbidity.

The diagnosis of spontaneous pneumothorax is difficult without a roentgenogram of the chest. Patients sometimes ascribe the onset of their difficulty to lifting, stretching, reaching, or childbirth. Major symptoms are shortness of breath and pain. The latter may be a constant, dull ache or may be aggravated by deep respiration and coughing. When a tension or bilateral pneumothorax is present, the patient may be restless, very dyspneic, or even cyanotic and comatose. Auscultation with the stethoscope is seldom helpful. Palpation of the neck with deviation of the trachea to the opposite side, however, may lead one to suspect the proper diagnosis.

Alternatives of treatment other than open thoracotomy are attended with prolonged hospitalization and disability. Maintenance of constant negative pressure via a catheter inserted into the pleural space requires several days of hospitalization followed by inactivity and observation at home for fear of recurrence. More than one catheter may have to be inserted. This form of treatment has been somewhat simplified by the use of the Fuller-Clagett S-needle, but the duration of treatment remains the same.

Simple bed rest may require even a longer period of time. The insertion of irritants such as talcum powder or hypertonic solutions have not been very satisfactory.

Thoracotomy remains, then, the treatment of

choice. One can examine the entire lung, and if no bullae are readily apparent, the common finding is a small area of fibrosis or "scar" in the apex. Ehrenhaft¹ has shown that this scar is found in tuberculin-negative as well as tuberculin-positive patients and is, therefore, nontuberculous. In the midst of this small scar there is usually a tiny bleb which is the source of the pneumothorax. This may be seen more readily when the anesthesiologist vigorously applies transient positive pressure (to 25 cm. of water). This area is then excised by wedge resection, a portion of the pleura either roughened or removed, and the thorax closed. Most patients are out of the hospital in a week and may rest assured that the source of their pneumothorax has been removed.

Editorial Comment

Dr. Connolly is to be congratulated for taking a firm stand in expressing his opinions concerning the treatment of spontaneous pneumothorax. There are many thoracologists, however, who would consider his approach to the problem a radical one, and there are a few who would consider it a bit too conservative.

Perhaps one should fit the treatment to the individual patient or to the magnitude of the problem each patient presents. Certainly, many minimal pneumothoraces are undetected, perhaps are called "pleurisy," and heal without treatment. Some of those which are minimal require only brief observation after detection. The majority may be treated very satisfactorily by constant suction for twenty-four hours via a malleable S-needle, then observation for twenty-four to forty-eight hours. Total hospitalization may be two to three days. When surgery for uncontrollable pneumothorax is necessary, Dr. Connolly's operation may be applicable. Excision of the parietal pleura, however, has been done by many surgeons with satisfactory results. Recently, bilateral simultaneous thoracotomy has been proposed for unilateral spontaneous pneumothorax.

These comments are made so the reader will realize that the treatment of this condition is not stereotyped and that there is not unanimity of opinion concerning the proper treatment for every patient with a spontaneous pneumothorax.

HOWARD A. ANDERSEN, M.D.

Clinical-Pathological Conference

of Clinical Pathologists
DONALD F. GLEASON, Editor

CASE PRESENTATION—MINNEAPOLIS VA HOSPITAL

HENRY A. JOHNSEN, Jr., M.D.
SAMUEL NESBITT, M.D., Ph.D.
Minneapolis, Minnesota

First Admission (1939).—A forty-four-year-old white man, a chronic alcoholic, received serum therapy for Type II pneumococcal pneumonia of the right middle lobe. He had a reaction characterized by arthralgia and an erythematous eruption. The blood pressure was 145/80, the pulse rate 96 and the urinalysis was normal. There was no history of scarlet fever or renal disease. He had had gonorrhea in 1920 and had been treated for syphilis. The serum Wassermann and Kahn tests were positive.

Second Admission (1945).—He was hospitalized for a pneumonia of the right lung, in association with an hallucinosis and following an alcoholic debauch. The blood pressure was 140/85 and the pulse rate 130. The urinalysis was normal. The serum Wassermann was 3-plus and the spinal fluid Wassermann was negative.

Third Admission (October, 1950).—He was received in transfer from another hospital, where he had been given penicillin and digitalis. He was now complaining of severe exertional dyspnea and paroxysmal orthopnea, with intermittent ankle edema and cough for six months. The temperature was 98.0 degrees F., the blood pressure 150/108 and the pulse was 62 and irregular. The fundi showed only some arteriolar attenuation. The vital capacity was 2.4 litres, slowly expelled. Three urinalyses showed a maximum concentration of 1.015 and a trace of sugar in one specimen. A chest film revealed a resolving pneumonia of the right middle lobe, plus some ectasia of the ascending aorta. The ECG showed broad, notched P waves, frequent premature ventricular beats and depressed ST segments over the myocardium of the left ventricle. A course of penicillin was completed for latent lues.

Fourth Admission (February, 1951).—He was hospitalized after being recalled for follow-up. The blood pressure was 115/110 with a pulse of 62 and later was 140/90 with a pulse of 94. The cardiac silhouette had enlarged and there was evidence of early pulmonary

Dr. Johnsen is Instructor in Medicine and Instructor in Neurology and Psychiatry, University of Minnesota and is Physician-in-Charge, Psychiatry Research Laboratory, VA Hospital.

Dr. Nesbitt is a former Associate Professor of Medicine, University of Minnesota, and Consultant in Medicine, VA Hospital. His present address is 25 East 83rd Street, New York 28, New York.

Dr. Flink is Professor of Medicine, University of Minnesota and Chief of Medical Services, VA Hospital.

Dr. Gleason is Chief of Pathology, VA Hospital.

congestion. He was instructed in salt restriction and, after some symptomatic improvement, was released.

Fifth Admission (August, 1951).—He returned with a recurrence of dyspnea and dependent edema. On examination, the neck veins were distended. The right pupil was larger than the left but both reacted normally to light and accommodation. The blood pressure was 180/100. The pulse rate was 130 and irregular. There was a soft apical systolic murmur in association with a gallop rhythm. The ECG was unchanged. The brom-sulfalein retention was 12.5 per cent after forty-five minutes and the zinc sulphate turbidity was 18.5 units. He responded well to treatment and was discharged on digitoxin and salt restriction.

Sixth Admission (Dec, 1951).—He had complained of a sudden "heart attack" in which his arms had become stiff and numb and he had vomited. There had been no pain or dyspnea and the symptoms had been relieved by brandy. The blood pressure was 160/98 in the right arm and 146/90 in the left arm. The ECG showed frequent runs of premature ventricular beats from different foci and the QRS complex was widened. Five urinalyses revealed a maximum concentration of 1.016 and traces of sugar and albumin were noted. The hemoglobin was 12.2 grams per cent.

Seventh Admission (August, 1952).—He returned with recurrent dyspnea and edema. He was disoriented and was perspiring profusely. Moist râles were heard over the lung bases, a presacral edema was present, the neck veins were distended in a sitting position and Cheyne-Stokes respirations were noted. There was irregular attenuation of the retinal arterioles and two flame-shaped hemorrhages were seen near the right disc. The heart was enlarged and exhibited a gallop rhythm with a Grade 2 blowing systolic murmur at the apex. The blood pressure was 158/128 and the pulse rate was 130. A PA film of the chest revealed further increase in the heart size and in pulmonary congestion. Two urinalyses revealed traces of albumin and sugar, as on a previous admission. The fasting blood sugar was 71 mgm. per cent. The ECG now exhibited a complete left bundle branch block. The serum Wassermann remained positive. He again responded well to a regime of penicillin and salt restriction. Digitoxin was discontinued.

Eighth Admission (November, 1952).—The dyspnea and orthopnea had recurred but without edema. He had raised some blood-streaked sputum for two days. Precordial pain on exertion had become a problem since his last admission. Fine, moist râles were heard over the right lung base posteriorly. The heart was markedly enlarged. The second heart sound was well preserved and of equal intensity in the aortic and pulmonic areas. The blood pressure was 160/110. The fundi revealed focal and generalized arteriolar narrowing. The circulation time from arm to tongue was 20 seconds. He was digitalized and received aerosolized penicillin. He

again improved promptly and was discharged after eight days.

Final Admission (August, 1953).—The patient stated that he had continued to take his digitoxin and had felt fairly well until the two weeks prior to admission. At that time, after a heavy alcoholic intake, he had again suffered from increasing dyspnea, orthopnea and ankle edema. On examination he was apprehensive, very cyanotic and orthopneic. The neck veins were distended. The rectal temperature was 100 degrees F. The blood pressure was 170/110. The pulse rate was 145, with total irregularity. Moist râles were heard over both lung bases. The heart was grossly enlarged. The liver edge descended four fingerbreadths below the costal margin. There was minimal pitting edema of the ankles. The venous pressure was 28 centimeters of isotonic saline. The circulation time had increased to thirty-seven seconds. The ECG now showed rapid atrial fibrillation with multifocal, premature ventricular beats and an intraventricular conduction defect. Ten minutes following the administration of 0.4 mgm. of digitoxin intravenously, the rhythm was found to be regular and the rate 160. Within five minutes, however, atrial fibrillation returned and continued thereafter. He expired three hours after admission.

Discussion

DR. EDMUND B. FLINK: It is always a pleasure to participate in one of these conferences. There are many interesting features in this protocol. This man had at least three different episodes of pneumonia—one in 1939, one in 1945 and one in 1950. He might have had an agammaglobulinemia but there is a better and more common explanation for his multiple episodes of pneumonia, namely chronic alcoholism. He had a reaction to serum therapy which was characterized by arthralgia and an erythematous eruption. In other words he had serum sickness. The rest of his course, however, permits one to dismiss a hypersensitivity state as being of importance. He had an incidental history of gonorrhea and lues, incidental because it is unlikely that lues had anything to do with his subsequent course.

On the third admission some of his symptoms suggest the ultimate cause of this man's death. He complained of severe exertional dyspnea, paroxysmal orthopnea and some ankle edema. I am impressed by the word "paroxysmal." His blood pressure was 150/108 and his pulse was irregular. Later the electrocardiogram showed multiple, premature contractions of ventricular origin, as the cause of his arrhythmia. He probably did not have atrial fibrillation at that time. Notice that he had a vital capacity of 2.4 litres, slowly expelled. He was by this time 54 or 55 years old and undoubtedly had some emphysema. I do not think that emphysema was an important factor, however. He also had a resolving pneumonia but this, I think, was a secondary phenomenon. Notice that traces of glycosuria were found on several admissions. I believe that the glycosuria is significant. On the fourth admission his blood pressure was stated to be 115/110. Is that correct?

DR. NESBITT: Yes.

DR. FLINK: Someone must have written it incorrectly. You can have your choice. You can have 195, 185, 175 and all the way down to the 115 as stated for

the systolic blood pressure. It was probably 175 and someone wrote it to look like 115. On that admission it was first noted that his heart was enlarged. He had a recurrence of congestive heart failure as indicated by dyspnea and edema and it was noted that he had neck vein distention. He had some bromsulfalein retention and a high zinc sulphate turbidity, suggesting that he had cirrhosis of the liver. The diagnosis of cirrhosis in the presence of congestive heart failure on the basis of two laboratory tests is difficult.

The sixth admission began with the complaint of a sudden "heart attack," in which his arms became stiff and numb and in which he vomited. These symptoms should be considered with the severe exertional dyspnea and paroxysmal orthopnea which the man had in August. Notice that his ECG is becoming more abnormal as time goes on and that eventually he develops a left bundle branch block. This is not an uncommon sequence in a patient who has hypertension. Serial tracings reveal that the QRS complex becomes progressively more prolonged. This does not necessarily mean, in my opinion anyhow, that there was an occlusion of one of the coronary arteries.

On the seventh admission he had recurrent dyspnea and edema and profuse sweating appears to be another important clue. Notice now that his retinal findings had progressed. Irregular attenuation of the retinal arterioles and two flame-shaped hemorrhages were noted, which simply means that he had continuing hypertension. His blood pressure had never been very startling and yet he developed these retinal findings in association with an increase in heart size and congestive heart failure. Traces of sugar and albumin were again found in the urine. The fasting blood sugar was normal and I would like to ask if there were any other determinations of the blood sugar or of the glucose tolerance at any time.

DR. NESBITT: That is the only fasting blood sugar reported and there is no record of a glucose tolerance test.

DR. FLINK: The assumption can be made that he had intermittent hyperglycemia and that the blood sugar was normal at other times.

On the eighth admission the findings are not very different. However he had complained of some precordial pain on exertion for a few months before his return here. This is not surprising in a man who had persistent hypertension. Certainly with the combination of hypertension and his age and with episodes of congestive heart failure, it is not surprising that he should have had precordial pain, indicating that he undoubtedly had some sclerosis of his coronary arteries. His heart was markedly enlarged at that time. Notice that his blood pressure again was not very high. Incidentally, was a serial record of his blood pressure kept?

DR. NESBITT: No.

DR. FLINK: The circulation time was twenty seconds. One of the causes of congestive heart failure, of course, is hyperthyroidism superimposed on another lesion of the heart or on hypotension but under such circumstances the cardiac output would be increased, rather than

decreased. This is just a straw in the wind. Actually there is no other evidence for this and I probably shouldn't build a straw man just to knock him down, without any more evidence.

On the final admission he again had become rather ill in a short period of time. He had been drinking quite heavily and it is a little difficult to sort out cause and effect. He was apprehensive, very cyanotic and orthopneic. He had the signs of congestive heart failure again. His blood pressure was 170/110 and his pulse rate was 145 and totally irregular. This time he had atrial fibrillation with many premature ventricular beats. He died suddenly three hours after he was admitted to the hospital. I would like to see the x-ray films at this time.

DR. J. V. TESTOR (Resident in Roentgenology): I have selected some representative films from each of his hospital admissions. This is one from his first admission in 1939 and shows the middle lobe pneumonia that was described in the protocol. His next admission was in 1945 and here again we see extensive pneumonia, this time predominately in the right upper lobe. The remainder of the lung films appear clear and his heart appears to be of normal size in 1945. His third admission occurred in October, 1950, and we see the resolving right middle lobe pneumonia that was described. I believe there was no mention of cardiac enlargement in the protocol at that time, but I do have films here from the cardiac fluoroscopy which was done then and I think there is evidence that the heart had enlarged, especially in comparison with the earlier films. In the LAO projection it appears that the enlargement is primarily left ventricular. This man had lues and we looked for evidence of luetic aortitis, but were not overly impressed with the size of the aorta. For this man's age I would say it was within normal limits and I can see no evidence of calcification or of dilatation of the ascending portion of the aortic arch. There is no evidence of valvular calcification. On the next admission, in 1951, we see that the heart had become greatly enlarged in comparison with the previous studies. We have evidence of pleural effusion on the right. We also have evidence of pulmonary congestion. You can see the effusion running up into the interlobar fissure on the right. In August of the same year no appreciable change is seen. On subsequent admissions we see some pleural effusion on the left as well as on the right and the vascular markings are accentuated. In December, 1951, a comparison of the oblique films suggests an actual reduction in cardiac size. I think further cardiac enlargement was initially described on this admission. These films may have been taken after treatment because the over-all heart size does look smaller than it did on the earlier examination in August of that year. The final film taken in August, 1953, shows a massive cardiac enlargement with pulmonary congestion.

DR. FLINK: Is a film of the abdomen available?

DR. TESTOR: We have a single flat plate of the abdomen. One can see the liver edge and the liver does not

appear enlarged. I am not able to identify the spleen. The renal shadows are not clearly visualized either. No conclusive evidence of any abnormality within the abdomen can be detected from this film.

DR. FLINK: Thank you. I would like to ask whether serial weights were recorded on this patient.

DR. GLEASON: I looked for them. There aren't any weights recorded during the first two admissions. He weighed 146 pounds in 1950 and on subsequent admissions his weight fluctuated between 158 and 168 pounds.

DR. FLINK: After seeing the films, it appears that the emphysema must have been minimal. Perhaps the vital capacity was compromised by the pneumonia and congestive heart failure. I think he had some cirrhosis and he had lues which was treated and was insignificant. There was no evidence, as we have seen, of an aortic involvement by lues. The primary disease that we are concerned with is the hypertension with recurrent congestive heart failure. I have pointed out several places in the protocol where sudden attacks of heart failure had occurred. Paroxysmal dyspnea can occur in ordinary hypertension. In fact this is the usual manifestation of left ventricular failure, regardless of cause. There was no evidence of renal disease. He did have some albuminuria but this was minimal and there was a striking lack of any statements in the protocol relating to the kidney. I intended to ask about the blood urea nitrogen determinations. I assume they were normal.

DR. NESBITT: They were.

DR. FLINK: Of course primary hypertension is a possibility. This is the diagnosis usually made in a situation like this. I expect that a diagnosis of hypertension with hypertensive and arteriosclerotic heart disease was made clinically. However, the history of profuse perspiration and the sudden attacks of dyspnea are important. The word "paroxysmal" was used to describe the dyspnea. This use may have been inadvertent, but it is at least suggestive of importance to me. Of course it may have been used deliberately (*laughter*).

These considerations, plus the frequent presence of sugar in the urine in the face of a normal blood sugar, all make one think of a pheochromocytoma. There is one other extra-clinical reason for suspecting that diagnosis in this instance. I didn't think that I would be asked to discuss this case if it were just hypertensive heart disease. Therefore I am going to extend a long neck (which may not remain long for any period of time) and make a diagnosis of pheochromocytoma. I can defend that diagnosis on the basis of what we read in the protocol.

There are many reviews on pheochromocytomata, as you know. The paper on this subject given by Dr. Vernon Vix at our Medical Grand Rounds is a good source of information. There are two additional reports that I want to call to your attention. Minno et al. found fifteen cases of pheochromocytomata at autopsy which had been unsuspected clinically. One was suspected before death but the patient died so soon after arrival at the hospital that nothing could be done. The

hypertension was persistent in ten of these cases. Twelve of the patients died of the complications of pheochromocytomata. Pulmonary edema occurred in five and, in reviewing the literature on this subject, one notes that the development of pulmonary edema was generally found to indicate a poor prognosis. Pulmonary edema in ordinary hypertension, of course, is a grave sign also. There is another review of a selected group of cases by Green. He reviewed fifty cases and found definite sustained hypertension in thirty-seven of these. Only fourteen patients had paroxysmal hypertension. The sum of the two groups totalled fifty-one instead of fifty, however. Sustained hypertension was related to the duration of the presence of symptoms for the most part. There was definite cardiac enlargement in seventeen of the thirty-seven cases. There were ten who had left axis deviation on the ECG. Twenty had albuminuria. Azotemia was present in two cases. Some abnormality in renal status was present in twenty-four of the thirty-seven cases of sustained hypertension. At autopsy there was no significant renal pathology, however, in nine of the sixteen cases in this group that came to post-mortem examination. The major causes of death in the patients not operated were acute left ventricular failure, cerebral vascular accident and chronic congestive heart failure. I think on the basis of reviews of this subject, that my diagnosis can be at least defended. I hasten to add that I have entertained this diagnosis a number of times on previous patients but have been proven correct only in those instances where the diagnosis had already been suspected and where appropriate tests were confirmatory.

DR. NESBITT: Is there any further discussion? Remember that this may be the day we start to discuss garden variety cases in these conferences. Dr. Zieve, do you have anything to say?

DR. L. F. ZIEVE: I must say that I didn't think of a pheochromocytoma in this case, but now that Dr. Flink suggests it, I was wondering if Dr. Nesbitt had any further information tucked away to explain that pupillary inequality that occurred in 1951. Did he have any evidence of a vascular accident?

DR. NESBITT: No, there is no further description in the chart.

DR. R. E. SMITH: Dr. Flink asked me to collect the diagnoses made by the medical students and thereby relieve him of a lot of red herrings. The students did not suggest this diagnosis as a possibility and all but one of them thought very strongly of luetic cardiovascular disease. They mentioned a number of things which Dr. Flink has already dismissed. I think it is important that the students clearly understand why he does not consider syphilis to be an important factor in this man's demise.

DR. FLINK: I intended to discuss it a little more. For one thing, he does not have any calcification in the root of the aorta. I didn't know that and the protocol doesn't say so, but we see no evidence of it on x-ray. The protocol does call attention to some ectasia of the

aorta but that is not enough to make a diagnosis of luetic aortitis. There is a complete absence of any suggestion of aortic regurgitation. If lues were the cause of his illness, significant aortic regurgitation would be necessary as a cause for his heart failure. The pulse pressure was not increased on multiple examinations. He did have a Grade 2 systolic murmur but a diastolic murmur was never described. You might say that he could have had an aortitis, associated with an aneurysm, with embarrassment of the circulation through the coronary ostia, but this is improbable.

DR. ZIEVE: You led up to the implication that he also had secondary coronary artery disease. Would you care to elaborate on that point?

DR. FLINK: Yes. Hypertension of any cause may be associated with coronary artery disease.

MEDICAL RESIDENT: Was there any family history of cardio-vascular disease?

DR. NESBITT: No.

DR. FLINK: Was there anything to suggest the presence of neurofibromata?

DR. NESBITT: No. A peculiar generalized dusky hue was noted in the skin, however, even during those periods when the patient was not cyanotic. As Dr. Flink has already suggested, the patient was felt to have chronic hypertensive cardiovascular disease during his multiple admissions here.

Doctor Flink's Diagnoses

1. Pheochromocytoma
2. Secondary hypertensive cardiovascular disease
3. Congestive heart failure
4. Portal cirrhosis of the liver

Pathologic Findings

DR. GLEASON: At autopsy there was no ascites, edema or jaundice. However, there were 500 cc. of fluid in the left pleural cavity and 200 cc. in the right pleural cavity. That was somewhat unusual. If the pleural fluid is not largest in volume in the right side, it is almost always due to something other than simple congestive heart failure. In this man there was more fluid on the left side.

The heart weighed 725 gm. Differential weights were as follows: left ventricle, 300 gm.; right ventricle, 150 gm.; septum, 100 gm. Therefore both ventricles were enlarged. There was only minor atherosclerosis of the major coronary arteries and no scars were visible in the myocardium. All the valves were normal, as was the root of the aorta. The left lung weighed 700 gm. and the right lung 950 gm., both being much heavier than normal and both being very wet. Much frothy fluid was expressed from the cut surfaces. The spleen weighed 100 gms. The liver weighed 1,950 gm. and was markedly "nutmegged" in character. There was a scar just past the pylorus which was suggestive of an old healed duodenal ulcer. The right kidney weighed 200 gm. and the left kidney 275 gm. Grossly, there was a small

amount of fine pitting on the surfaces of the kidneys, but they were otherwise normal. The abdominal aorta was moderately atherosclerotic in its lower abdominal portion. The adrenals appeared normal. The remaining gross autopsy examination was essentially normal. Permission for examination of the brain could not be obtained.

On microscopic examination, there was slight thickening of individual myocardial fibers. There was a tiny amount of fine fibrosis also noted throughout the myocardium. The kidneys were surprising in that they showed very little evidence of hypertension. There was some hyaline atherosclerosis and moderate intimal thickening of the larger intrarenal vessels but nothing that was not consistent with the patient's age. The lungs were congested and there was a small amount of precipitated protein material in the edema fluid in the alveoli. There was a small amount of early bronchopneumonia. The adrenal was considered normal at the time of autopsy, when it was sectioned in a few places before being placed in the formalin fixative. However, at the time of further sectioning of both glands in the preparation of material for tissue slides, a small tumor was found inside the substance of one of the glands and this seemed to be located within the medulla. On microscopic examination, the cortex was markedly thinned and compressed by this tumor, which is made up of cells that resemble those of the adrenal medulla (Fig. 1). This is a pheochromocytoma and it is apparently benign. It is very small, measuring about 1 cm. in diameter on the slide. It is not a cortical adenoma. At the time of preparation of the tissue slides, a portion of the fixed tumor tissue was taken out of formalin and subjected to the silver staining process used for carcinoid tumors. The tumor cells took up a small amount of the silver in the form of tiny granules. This silver stain for carcinoid tumors will stain the epinephrin-like material of pheochromocytomata in fresh tissue, but is not usually effective in material that has been fixed very long in formalin. I think we were lucky to get a lot of silver staining here (Fig. 2). Another characteristic feature of a pheochromocytoma, like some carcinoid tumors, is an affinity for chromium salts. Recent work has shown that both types of tumors secrete vasoactive amines, 5-hydroxytryptamine (serotonin) being elaborated by some carcinoid tumors and catecholamines (epinephrin and norepinephrin) being elaborated by functioning pheochromocytomata. These amines, or their precursors, are probably responsible for the cytoplasmic argentaffin and chromaffin granules seen in these tumors. In order to demonstrate the chromaffin properties of this tumor, we would have had to suspect its presence beforehand and fix it in a modified Zenker's solution, containing chromium salts. This is not a routine procedure.

Section of the liver showed a minimal portal cirrhosis and some congestion in the center of the lobules.

Tumors of this size have been reported as being associated with hypertension. We asked Dr. E. T. Bell about it and he has seen several of this size. We feel strongly that this tumor was the cause of the patient's difficulty.

MEDICAL RESIDENT: I wonder if a BMR was done. I remember a case of pheochromocytoma that was picked up because of the results of this test.

DR. ZIEVE: Yes, but that would have been worthless in this case. He had congestive failure and the associated dyspnea would invalidate the procedure.

DR. FLINK: It should be noted, however, that per-

GOMORI SILVER STAIN OF ADRENAL

Fig. 1 (above) Small pheochromocytoma located next to intraadrenal vein and compressing cortex.

Fig. 2. (below) Section of tumor magnified 440 \times and demonstrating intense argentaffin staining of cytoplasmic granules. Photographs by Medical Illustration Service, VA Hospital, Minneapolis.

sistent hypermetabolism without hyperthyroidism should make one suspicious of a pheochromocytoma. As a matter of fact, a pheochromocytoma may be wrongly diagnosed as hyperthyroidism because of weight loss, sweating and hypermetabolism. The statement is made in the literature that the size of the tumor has little relationship to its manifestations. I don't know how small the size can be for that statement to be valid. I was ready to look for a trap door when you said the adrenals appeared normal (*laughter*).

MEDICAL RESIDENT: What would the surgeon do when he saw that normal appearing adrenal?

DR. FLINK: The patient would have to be explored from an anterior approach and the adrenals examined bilaterally. If the diagnosis had been suspected and the

proper tests were positive, then the surgeon would have to look very carefully. He might have to look in other areas. He might be misled and not take out the adrenal, even with positive benzodioxane, regitine and histamine tests. I think that in the periods of his low blood pressure, it would have been worthwhile to do a histamine test on this patient. In retrospect, all three tests should have been done, of course. The measurement of the twenty-four-hour urinary excretion of catecholamines is an even more important test to perform.

MEDICAL STUDENT: When these tumors are multiple, do they ever occur elsewhere, without being present in the adrenal? Do they occur in the carotid sheath or anywhere along the sympathetic chains?

DR. FLINK: Multiple pheochromocytomata occur most commonly in both adrenals. There is no reason why they cannot occur in other chromaffin tissues, however. When they occur in both adrenals, a portion of the cortex can be saved so that the patient does not develop adrenal cortical insufficiency. Again, the anterior approach for seeking these tumors is advisable, since one can examine both adrenals, the gland of Zuckerkandl and the peritoneal cavity and retroperitoneal areas. When the tumor is extra-adrenal in position, the problem is very much greater, of course. This patient's very small tumor reminds me of a patient at the University Hospitals who had positive benzodioxane,

regitine and histamine tests and yet no tumor was found on exploring the adrenals. This leaves one with a very uneasy feeling.

DR. SMITH: I would like to ask the pathologist to review the pathologic classification of tumors of the adrenal medulla. Is it a functional or an anatomical classification?

DR. GLEASON: Given the location in the adrenal, pheochromocytomata have a fairly characteristic morphology. This benign one looked much like the adrenal cortex except that the tumor cells were granular instead of vacuolated. The malignant pheochromocytomata may be much more variable.

Final Anatomic Diagnoses

1. Pheochromocytoma with hypertension
2. Myocardial enlargement and congestive heart failure
3. Minimal portal cirrhosis

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Minnesota License of Washington Physician Revoked for Drug Addiction

The Minnesota State Board of Medical Examiners on November 8, 1957, revoked the medical license held by Dr. Orin P. Thorson of Bremerton, Washington. Dr. Thorson was found guilty by the Board of habitual indulgence in the use of dilauid and morphine sulphate. After evidence was presented to the Board that Dr. Thorson had issued prescriptions for morphine sulphate for his personal use at a time when he did not possess a valid Federal narcotic tax stamp, Dr. Thorson admitted the truth of the charges in the citation that had been issued by the Board in his case. Dr. Thorson had also been charged with issuing numerous prescriptions for dilauid for patients who, pursuant to his instructions, had the prescriptions compounded at various drug stores in the State of Washington and then delivered the dilauid tablets to Dr. Thorson, who then removed part of the dilauid tablets for his own use and substituted non-narcotic drugs therefor.

Dr. Thorson's Minnesota medical license has been previously suspended twice by the Minnesota State Board of Medical Examiners for drug addiction. On May 14, 1948, Dr. Thorson's license was suspended for a period of three years and on February 14, 1952, the Board suspended his license for five years. When the suspension of Dr. Thorson's medical license expired in February, 1957, the Board learned that he had again been the subject of an investigation by agents of the Federal Bureau of Narcotics in the State of Washington, whereupon the present proceeding for the revocation of his license was instituted. Dr. Thorson, who was born at Madison, Minnesota, on September 4, 1900, received his M.D. degree from the University of Minnesota on June 11, 1928. He was licensed by examination in Minnesota in 1927 after obtaining his M.B. degree. Dr. Thorson was engaged in the practice of medicine for twelve years at Northfield, Minnesota, before moving to Bremerton, Washington, in 1940.

License of Minnesota Physician Revoked for Misconduct

On November 8, 1957, the Minnesota State Board of Medical Examiners revoked the medical license held by Tauno E. Ketola, M.D., 29 years of age, who practiced medicine for a short time in 1956 at Cloquet, Minnesota. Dr. Ketola was present at the hearing and admitted the truth of the charges contained in a citation for the revocation of his license which had been issued by the Board on July 16, 1957. Dr. Ketola was charged in the citation with conducting himself as a licensed physician and surgeon immorally, dishonorably and unprofessionally in that he had committed immoral, improper and indecent sexual acts with more than eleven persons of the male sex between 1953 and February, 1957. There was no evidence that any of these persons had ever consulted Dr. Ketola as a patient.

Dr. Ketola, on April 15, 1957, had entered a plea of guilty before the Hon. Mark Nolan in Carlton County District Court to an information charging him with the crime of sodomy. The charge had been filed against Dr. Ketola because of his misconduct with boys who were minors. Judge Nolan continued the case for a pre-sentence investigation and ordered Dr. Ketola to undergo a psychiatric examination. After he had been hospitalized and given psychiatric treatment, Dr. Ketola again appeared before Judge Nolan on October 3, 1957, at which time the Court continued the matter for one year when the case will be reviewed and Dr. Ketola will be sentenced.

Dr. Ketola, who was born in Iron, Minnesota, on July 6, 1928, graduated from the University of Minnesota with an M.D. degree on June 13, 1953. He was licensed to practice medicine in Minnesota in the following month and subsequently he served an internship for one year at the Highland Alameda County Hospital in Oakland, California. In May, 1956, Dr. Ketola was separated from the United States Air Force for similar misconduct.

GOVERNMENT

I am happy to accept the invitation to write a series of editorials on "Government" for MINNESOTA MEDICINE. I regard it as an opportunity to perform one of the important functions of my office—that is, to use every available means to bring about a greater understanding of the problems of government on the part of the people of our state.

There are some significant differences, and some important similarities, between the practice of the science and art of medicine and the science and art of government. The medical profession requires great ability, as well as long, arduous, specialized training. It requires constant and alert attention to the latest scientific advances. Facts, information, and understanding are of utmost importance.

The medical profession makes use of its great scientific development to contribute to the health and happiness of human beings. Its goal is not the amassing of skill and knowledge as an end in itself, but rather as tools to use to relieve human suffering. And therefore members of the medical profession must understand the needs and wants of the individuals whom they serve. The art of healing and the science of the prevention of disease are of utmost importance to human welfare.

What can we say about government? By some, it is regarded as "a necessary evil," but this concept is not only frivolous but totally wrong. Human beings could not live in the world of today without government, and nothing that is essential to human society can be regarded as evil in itself. To be sure, there are some governments in the world today—as there have been in the past—which we regard as evil in their methods and goals. And perhaps there is no government in which some evil cannot be found. But in a free, democratic government such as ours, the responsibility for serious faults must lie, in the last analysis, with all of the people.

Government, like medicine, is dedicated to the welfare and happiness of human beings. True, physicians deal primarily with individuals, while

government deals with individuals in their relationships with each other. But medical science must also consider human relationships. It cannot set standards for a pure water supply, or prevent epidemics, by dealing with individuals alone. And government must consider the dignity and worth of each individual human being if it is to maintain the freedom to which we in the United States are so thoroughly committed.

But if government and medicine are similar in their common dedication to human welfare, what about other characteristics? Those who engage in the medical profession are highly trained and carefully selected for aptitude and ability. What can be said for those who engage in government?

Many are, of course, extremely able and well trained. Government today has become complicated and specialized, and must seek out and secure the services of well qualified men and women. But it is an essential part of our democratic philosophy of government that those who hold the policy-making positions in government must be elected by the people. For such officials, the absolutely necessary qualification is their ability to secure the majority of the votes. In the final analysis, then, every voter not only shares in the government, but must be held responsible for the wisdom of the choices he makes.

Good government, therefore, depends not only on the ability and integrity of those whose principal occupation is in government, but also on the ability and judgment of the people. It requires not only an intelligent and educated electorate, but one that is adequately informed on public questions. The decisions that voters must make involve questions too complicated to be solved by slogans and shibboleths. They require a real understanding of the problems involved.

ORVILLE L. FREEMAN, *Governor*

IRON METABOLISM

Iron is an essential constituent of hemoglobin, myoglobin, and certain respiratory enzymes such as cytochrome and catalase. It is thus intimately concerned with tissue respiration. Because of the

body's need for iron, provision must be made for its absorption, transport, storage, and perhaps also for its excretion.

That there is more iron in blood than can be accounted for by the presence of hemoglobin alone was suggested as early as 1872. The presence of iron in normal human serum, however, was not established definitely until 1927. Normal human serum contains from 60 to 180 micrograms of iron per 100 cubic centimeters. In the serum, iron is bound to a beta-1-globulin, siderophilin. Normal serum contains a sufficient amount of siderophilin to bind approximately 300 micrograms of iron per 100 cubic centimeters. The normal iron-binding capacity of serum is therefore approximately one-third saturated. Serum iron is transport iron, i.e., iron which is on its way from the intestinal tract to storage sites, from storage sites to hematopoietic tissues, or from sites of blood destruction back to storage sites. Serum iron is a dynamic fraction, showing considerable variation throughout the day in a given individual as well as from day to day.

Iron is absorbed from the intestine principally in the ferrous state. Because food iron is mainly in the form of insoluble ferric salts, food iron must be brought into solution and reduced before it can be absorbed. While hydrochloric acid of the stomach is probably of some importance in bringing ferric iron into solution, the reducing substances in the gut such as vitamin C and glutathione are of considerably more importance in iron absorption. Absorption occurs mainly in the duodenum and upper jejunum. There is evidence to suggest that the absorption of iron is regulated, in part, by the body's need for this element. Urine, bile, and sweat each contain small amounts of iron. The total amount of iron excreted in this manner amounts to less than 1 milligram per day and is not increased when iron intake is increased. The body thus possesses no regulatory mechanism for the excretion of iron. Women lose an additional 20 to 50 milligrams of iron with each menstrual period.

Another important factor in the regulation of the serum iron level is the balance at any given moment between blood destruction and new blood formation. Normal blood destruction accounts for the release of approximately 25 milligrams of iron each day, and this must be transported back to the marrow for new blood formation. Nor-

mally, of course, destruction and formation are in balance although at any given moment it is likely that one or the other may be proceeding at a higher rate. In certain disease states, this balance is disturbed. When blood formation is decreased to a greater degree than blood destruction as, for example, in aplastic anemia, the serum iron will be high. On the other hand, when the rate of blood formation is relatively faster than that of destruction, as in iron deficiency anemia, the serum iron will be low.

For reasons that are not well understood, infection seems to result in an increased demand for iron by the normal storage sites, that is, the liver, spleen, and bone marrow. Because of this demand, the serum iron is usually low in the presence of infection even in the absence of anemia. An exception to this general rule is hepatitis which is usually characterized by a high serum iron. This is thought to be due to the release of iron from damaged liver cells.

The normal adult male body contains approximately four to five grams of iron. Of this, almost 60 per cent occurs as hemoglobin iron, approximately 20 per cent as the iron of myoglobin and the respiratory pigments, and the remaining 20 per cent as storage iron. The iron of myoglobin and the respiratory pigments is inviolate; that is, it cannot be used for the manufacture of hemoglobin even in the presence of severe iron deficiency. On the other hand, stored iron, which is present in the liver, spleen, and bone marrow, is a very mobile fraction and can be used readily when there is excessive iron loss or insufficient iron intake. In the management of iron deficiency anemia, the necessity for replenishing the depleted iron stores is all too frequently overlooked. Iron therapy is often stopped too early with the result that the anemia recurs.

Perhaps the most interesting disturbance in the metabolism of iron is hemochromatosis, a condition characterized in its fully developed form by widespread hemosiderosis, cirrhosis of the liver, diabetes, and bronzing of the skin. Since, as has been pointed out above, the body has no mechanism for the regulatory excretion of iron, hemochromatosis must represent a disorder of iron absorption. Considerable evidence suggests that the disease actually begins very early in life, long before symptoms are manifested. In recent years, encouraging results have been obtained in

the treatment of this disorder by removing large amounts of iron from the body by means of repeated venesection.

Iron is an essential constituent of the body. Disorders of iron metabolism can be treated most rationally when its metabolism is well understood.

ROBERT B. HOWARD, M.D.

CALENDAR HISTORY

The Twin Cities have the largest per capita distribution of calendars and the West Coast the largest distribution per capita for area. The largest religious calendar orders originate in New York City.

Brown & Bigelow furnishes subject matter for every kind of business and industry. It produces 600 paper items in addition to 200 metal, plastic and leather advertising novelties. It turns out eight million decks of playing cards annually.

From a one-room operation in 1896 with one of the partners, Bigelow, its lone salesman, the Brown & Bigelow company has grown to a huge operation with vast plants in St. Paul and Minneapolis. Its 1,100 salesmen, working out of fifty-nine district offices, cover the entire country. It has hundreds of representatives in foreign countries.

This vast operation has been built principally on the need for a device with which people can keep track of the days, months, and years—the calendar.

With emphasis on developing quality and beauty in the calendar line, Brown & Bigelow has brought the product a long way from the simple reproduction of figures which tell the day.

The pad of dates hanging on the wall serves its function but has little glamour. A businessman wishing to carry a message to this customer or prospect, via the calendar he distributes, is anxious to make an impression.

As result, Brown & Bigelow has enhanced its calendar pad with illustrations of the finest works of nationally-known artists. This results in real advertising pull for the merchant.

In addition, certain types and subjects are given to specific businessmen under a franchise so that year after year his firm and product are identified with the calendar he sends out.

For instance, the Boy Scout calendar published exclusively by Brown & Bigelow for thirty-three years is one of the best in the line. Illustrated

by Norman Rockwell, America's famed artist, this calendar is specifically designed for public places, Boy Scouts, Cub Scouts and parents. In its various editions, this piece fosters co-operation with the Boy Scout movement and is designed to develop good citizenship.

The national organization of the Scouts receives royalties on each one of these calendars sold by Brown & Bigelow. This official Boy Scout calendar is given under franchise to a merchant who may have exclusive right to its use in a specific territory.

The 4-H club calendar is published under similar arrangement with royalties going to support the national 4-H camp.

The calendar carrying a portrait of the Dionne quintuplets painted exclusively for Brown & Bigelow was a popular item. This series was discontinued after the death of one of the quints.

Although early American calendars were designed specifically for hanging in offices and public places, the trend toward home calendars has given impetus to the development of the calendar business.

A national independent survey has disclosed that a housewife averages two calendars in the home but is looking eagerly for more. Those questioned merely sought additional variety and said that if they were given the choice of more subjects, they would gladly accept them for home use.

The attention-getting quality of this home necessity was proved by housewives when queried at their doors. They were able to recall the advertisers' names on 78 per cent of all the calendars hanging on walls or placed on desks and tables about the home.

In this still wide-open field, Brown & Bigelow keeps growing. It continues to develop quality along with quantity. New types of calendars, new illustrations, new sizes and new utility features are introduced each year to make the calendar as much a functional part of every room as the very wall itself.

SAFETY GLASS AND YOUR CAR

Safety, in respect to the glass areas in your car, starts with the finest quality of glass—safety plate glass. In addition to the physical protection af-

Second in a series of three editorials on safety glass.

MINNESOTA MEDICINE

forded the occupants in case of accident, it involves the quantity of vision—how expansive a field of view is provided.

Educators who teach people how to drive safely agree that a wide visual field is a prime requisite in accident prevention.

The area one can see from side to side while looking straight ahead is called your field of vision, according to the driver training textbook of the American Automobile Association. There are standard tests for peripheral vision and the average person can see a 180 degrees field. Some even cover 195 degrees and more. However, there are a few persons who have "tunnel vision." They see only straight ahead, as if looking through binoculars. Necessarily, they are at great disadvantage when driving through intersections and at all times in heavy traffic.

Older motor cars with narrower windshields, divided strips down the center, and prominent forward corner posts, gave every motorist some of the characteristics of tunnel vision.

However, with the advent of the panoramic windshield, a few years ago, the tunnel view is pushed aside by a much wider windshield of greater area, with corner posts moved back and obstructions in the windshield itself removed.

For instance, the area of windshields in current models of the Chevrolet car are now 67 per cent greater than those of the 1947 model. Much the same trend has been shown in all other General Motors cars and many other popular makes.

Another move to increase the quantity of vision has been the enlarging of backlights. In the 1957 Chevrolets the backlights are 180 per cent larger than they were ten years ago.

Taken together, the big back windows and the large panoramic windshields benefit other drivers as well as you when seated in the driver's seat of your own car. The man in the car behind, can see right through your car and take in much of the area ahead of you. In some situations one may see through two or three cars ahead and for some distance through cars at the rear. The more warning a driver has, the less chance there is for accident.

Large rear windows also provide a safety factor for backing out of a driveway.

To prove up the safety advantages of a more expansive view, one needs only to compare specific

views from the modern car with the same views from the finest cars produced ten years ago. Not only have the seeing areas become larger but the engineers have designed the car itself to employ these windows to the best advantage for the driver.

The greater efficiency of vision embodied in the panoramic windshield was not achieved without a struggle. It took ten years of research work to bring this product to production. The first of the panoramic windshields were installed in 1954 models of Cadillac, Buick and Oldsmobile cars. Libbey-Owens-Ford Glass Company (largest manufacturer of automotive safety glass) began its investigations of curved glass in automobiles in 1941. In 1943 they engaged the late Dr. Adelbert Ames, Jr., and Dr. Kenneth N. Ogle, of the Dartmouth Eye Institute, to assist in the research. Their studies found that one specific type of windshield curvature would increase the comfort and safety of the driver even over the flat windshield then in use. That gave the manufacturers their cue. However, whenever curved glass is introduced into the field of view, quality of vision must be carefully assessed. Car manufacturers followed this investigation closely over several years and many changes in styling and body design were effected merely to preserve the best optical effects in the new curved windshields.

Most important result of all the factory research was an exclusive Libbey-Owens-Ford method of manufacture which costs more but produces a superior panoramic windshield.

In a less expensive process, one starts with a flat block size of $\frac{1}{8}$ -inch glass cut to a curved pattern. Then the patterned shapes are bent under heat to the finished curvature. In the Libbey-Owens-Ford process the rectangular block sizes are first bent to curvature under heat and the trimming of the peripheral waste glass is done later. It was early discovered that it was in the peripheral area of the glass adjacent to the mold supports where uneven bending caused distortion and gave poor optical results. Yes, the two processes turn out products which fit the testing templates but only the latter process brings forth a windshield that also provides all-over superior optical results for the car driver.

WILFRID HIBBERT

Libbey-Owens-Ford Glass Company

CONFESSIONS OF A HOBBYIST

Baking

Some five years ago, while mixing the ingredients for a photographic formula, it occurred to me that it shouldn't be hard to mix cooking ingredients. After poring over a couple of cookbooks, I wasn't so sure. Expressions like "Beat until light," "Fold in the whites," and "Cook until done" seemed to me a bit vague. Then I got hold of Betty Crocker's Picture Cookbook, and light began to dawn. Not only were there pictures of how to do things, but there were precise measurements, and precise information about temperatures and times. That was right up my alley, and I got busy and made two loaves of white bread. It was good, too! It was a short step from this to cakes and pies, and I tried nearly every cake and pie in the book. The payoff came when my daughter asked me to make her wedding cake. I set up a pilot plant, so to speak, and made a small one, and when this came out all right, got busy with the big, three-story cake. It had a priming coat of one kind of frosting, and a finishing coat worked into patterns with a squirt-gun. Since it uses eighteen egg whites, the eighteen yolks had to be made into cupcakes. We got tired of cupcakes!

Pies are real fun. The only difficulty in making good piecrust is getting the water mixed in evenly, and I fixed that by putting my four tablespoonfuls of water in a pop-bottle with a five-cent aluminum sprinkler cork. Chiffon pies are complicated to make, but are delicious, and well worth the trouble.

I'm not interested in cooking on top of the stove. The utensils are too hard to clean up, and besides, if I got good at it, I might have to take over. I shouldn't know how to cook a lamb chop, even if I had money enough to buy one. I admit without shame that if left alone, it is simpler to get a package of corn-flakes and some cream. Once I did make eight quarts of watermelon pickle, and came to grief, not knowing that the boiling point of vinegar, sugar and water, suddenly changes when the mixture boils down. Without warning, the whole thing went WHOOSH—and the innards of the stove aren't cleaned up yet.

I do put up a lot of cranberry sauce, because

my relatives in the East raise some 10,000 barrels of the things every year, and send me a large box of an especially fine variety. Outside of this, as far as I am concerned, baking is real fun, but stove-top cooking—NO.

JOHN DEQ. BRIGGS

CAN YOU BE INSURANCE POOR?

The Young Physician

From what the life underwriter hears, just about everyone must be "insurance poor." In many instances a man says he is in order to divert the interview, but there are occasions when an individual is paying more for insurance of one type or another than is practical, assuming this is what is meant by "insurance poor."

Many individuals could be said to be "insurance poor" for another reason—not because they own too much coverage, and not because their premiums are too high in comparison to income, but because their premium dollars are not being applied wisely to cover their needs.

For example, recently a young physician rejoined his family after a two-year confinement for tuberculosis. He is currently finishing his last year of residency, which was interrupted two years ago. Unfortunately, for many years to come his application for life insurance will be rejected, or if not rejected, premiums will be rated high and benefits will be limited. Previous to his illness he had purchased \$15,000 of permanent life insurance including Waiver of Premium for Disability, carrying a premium of approximately \$400 per year. His life insurance premiums were waived during his illness, but he had no disability income.

This young physician, like others in special fields, has \$40,000 to \$50,000 invested in the cost of his education and deferred or lost earnings. It is said that there are two ways for a physician to protect his investment: (1) to live and maintain good health while applying it in his practice or (2) to insure. Because he cannot determine how long he will live and be able to practice, the only means available to protect his investment is to insure, with both life and disability insurance.

A prominent insurance educator has advocated that an insurance buyer determine how much insurance is needed to do the job intended, and that he pay as much premium as he can afford for that coverage. The amount of premium will determine

the type of insurance. For the young professional man (with limited income and seemingly unlimited needs for income) this will require the use of a high percentage of term insurance until income permits more substantial premiums for permanent insurance. It is more attractive, in some ways, to use the limited premium to buy a smaller amount of permanent insurance, recognizing that all or a portion of the premiums paid can be refunded as cash value if the policy is terminated. Furthermore, the interest on the cash values will reduce the actual cost of the insurance over a period of years. Many individuals will be lucky enough to complete their insurance program on the basis of purchasing smaller amounts of permanent insurance periodically. That was not the case with the young doctor just described. He based his planning on the premise that he would be insurable when he decided to expand his program and that quite likely he would not die or be disabled before he completed his program.

It appears that this young physician could be said to be "insurance poor" because he needs and could have owned more protection for his \$400 per year. To illustrate: for the \$400 per year it would have been possible for him to purchase a combination policy carrying \$10,000 permanent insurance and \$30,000 of term insurance, with a rider providing for waiver of premium and disability income benefits for total and permanent disability.

If this physician had used this plan he would have protected his investment for the benefit of his family in event of premature death and for himself in event of disability. Also, he would have preserved the right to expand his permanent insurance up to \$40,000 by use of the conversion privileges on the term insurance, regardless of health at a later date.

Would owning this plan make him "insurance poor"? It is obvious the latter course of action would have been the correct "corridor in the maze," the more advantageous alternative. You might say that hindsight is much better than foresight. You might say that this doctor's misfortune was a remote possibility. But you could say, also, that it is the remote possibilities for which we insure.

HERBERT F. MISCHKE, *C.L.U.*

DEFINITION OF THE TUBERCLE BACILLUS

A Bacteriologist's Definition.—The tubercle bacillus (human, bovine and avian types) belongs to a parasitic branch of the family of mycobacteria whose non-parasitic branches are widely distributed in the soil. Mycobacteria belong to the order of Actinomycetales, which includes the families of Actinomyces, Streptomyces and Nocardia—the members of which have a complex life history:—a generation of rods interchanging with a mycelial generation, each with their own mode of reproduction. Mycobacteria and Nocardia are now known to have a common ancestry.

The parasitic branches of the family of Mycobacteria occur and reproduce as rods. Only the tubercle bacillus of the avian type, if grown in culture, may show a *reversion* to ancestral forms of growth and reproduction. The life history of mycelial avian strains shows a development in stages from *non-acid-fast* mycelial structures to colonies of acid-fast bacillary rods and filaments. From different branches of the same mycelium colonies of the "non-orientated," the "orientated" type may arise. This family history explains the "pleomorphism" often seen in ordinary cultures of avian type bacilli.

In the human and bovine type, reversion to the mycelial growth habit may also occur (*in vivo* as well as *in vitro*) but is rare. However non-acid-fast filaments and rods may precede an acid-fast generation. Colonies of "non-orientated" and "orientated" type (cords and ropes) are a common occurrence and can be explained, in view of the developments in mycelial avian strains, by the family history of the mycobacteria.

While in culture as well as in animal tissues, at the time when infection had become established, the human tubercle bacillus seems to reproduce as bacteria do, there are certain differences and the question of the reproductive processes in the *invasive* phase of infection is still a matter of controversy.

A Cytologist's Definition (from observations with the electron microscope on fixed specimens).—A typical rod-shaped tubercle bacillus resembles ordinary bacteria in its finer structure. It consists of a protoplast enclosed in an outer cell wall. The protoplast has a plasma membrane which lies just inside the cell wall and which

has been shown to possess a number of enzymes, including those necessary for cell division.

The cytoplasm is granular, as in other bacteria, and contains a number of characteristic structures or organelles such as: (a) one or more larger granules which appear sharply defined and very dense in the electron microscope, due to their high content of metaphosphates (which have a possible function in energy metabolism); (b) oxidative-reductive enzymes which in animal cells are associated with the mitochondria and which in the tubercle bacillus are distributed throughout the cytoplasm apparently not associated with structured organelles; and (c) the nuclear apparatus, which is similar to that of ordinary bacteria, and consists of networks of coiled fibrous material, which is supposed to contain the genetic material of the cell.

The division of the rods normally occurs by the formation of a cross wall and the separation of the two daughter cells, each containing part of the nuclear apparatus. Some rods, however, grow into filaments and a different reproductive process takes place in which rows of intracellular units form within the bacillus. Each unit has its own limiting membrane and the process is suggestive of spore formation.

Mycelia in avian strains are found to be formed from chains of individual cells which reproduce by crosswall formation and also by budding, the buds arising from bulges in individual cells.

A Pathologist's Definition.—A pathologist would define the tubercle bacillus as the causative agent of tuberculous disease. It has the ability to multiply in the tissues of a susceptible host and causes a specific tissue response: tubercle formation, necrosis and caseation.

In tissue culture, bacilli also multiply freely in macrophages, with both partners living together apparently unharmed for shorter or longer periods until the growing cluster of bacilli disrupts the cell. But contrary to growth *in vivo* there is no specific tissue response, no sign of tubercle formation, no toxic action and no caseation. Furthermore, bacilli multiply in macrophages of tissues from animal species which are known to possess a native resistance to infection.

The clue to the definition of the tubercle bacillus as a parasite and its pathogenicity may well lie in the difference between the host-parasite relationship in the *in vivo* and *in vitro* infection.

A study of the life history of the tubercle bacillus in its parasitic existence, now in progress, will throw more light on the problem of pathogenicity.

E. M. BRIEGER, M.D.
Strangeway Laboratory
Cambridge, England

SIMPLE REVERSIONARY TRUST

One of the physician's most pressing financial problems today is his high Federal Income Tax.

He would like to reduce it without reducing his earnings . . . and while this seems like "pie-in-the-sky," it can be done through the use of a simple reversionary trust with the income payable to and taxable to the beneficiary.

For years, trusts have been widely used for tax and other purposes. The reversionary trust is relatively new, however, and trusts that transfer the tax liability to the beneficiary are downright rare.

The reversionary trust differs from the standard trust in that the corpus (body) of the trust reverts back to the donor after a period that cannot be less than ten years.

This enables an individual who does not need the income from certain investments to divert that income to a beneficiary for a period of not less than ten years, and, after that time, to receive back his original investment.

Then, if the trust is properly drawn, the beneficiary is also made responsible for the tax which can mean the difference between a minimum 20 per cent tax which the trust would ordinarily pay and no tax at all because of the beneficiary's normal tax exemption.

Thus, the simple reversionary trust becomes one of the most effective legitimate opportunities for a doctor, temporarily, to shift to others some of his investment income, and, more important, also the tax burden that goes with it.

Ideal for Parents

This simple reversionary trust is ideal for parents with young children who will later go to college and for those with dependents with little or no income of their own.

For example, on an investment yielding \$500 annually, a physician in the 50 per cent bracket would have to pay \$250 tax . . . but his son or daughter would not have to pay any tax at all

if they received the \$500 and didn't have too much other income.

Since any taxpayer can have taxable income up to \$675.00 without having to pay any Federal Income Tax, and because \$50.00 of the dividend income would be nontaxable, the annual dividend income to the beneficiary could be up to \$725.00 per year, reduced by income from other sources, if any, without his having to pay any Federal Income Tax.

If the beneficiary is a child under nineteen (or a child in school, regardless of age) and one furnishes over one-half of that child's support, one would not lose the dependency exemption for that child because of the trust income. However, if the beneficiary is an adult dependent other than the above, then it is recommended that the beneficiary's gross income from all sources be less than \$600.00 per year to prevent loss of dependency exemption.

Here is a table showing how much more one would have to invest or how many times the rate of return one would need, to accomplish results equal to this trust.

If Tax Bracket is	Earnings necessary to clear \$600.00 after Federal Income Taxes	(Without Trust) Number of times investment principle must be increased to clear same as with Trust (up to \$600.00).	(Without Trust) Number of times the rate of return (of Trust) must be increased on a specified investment to clear the same amount (up to \$600.00).
30 %	857.14	1.42	1.42
40 %	1,000.00	1.66	1.66
50 %	1,200.00	2.0	2.0
60 %	1,500.00	2.5	2.5
70 %	2,000.00	3.33	3.33
80 %	3,000.00	5.0	5.0

What to Use as Corpus of Trust

Practically anything can be used as the corpus or body of a reversionary trust. A mutual fund is very suitable as it provides a broad investment program in one security under the supervision and management of professional analysts. It is simple to use in a trust and since most funds are composed largely of common stocks, it also provides a hedge against inflation.

The value and dividends on the shares will increase or decrease with changes in market value and income of the investments in the fund, of course, but the management has the responsibility of managing the fund to meet changing conditions, to the best of its ability.

This is very important since a reversionary trust must run a period not less than ten years.

How Much to Put in Trust

A trust can be written with a corpus of any amount from \$1 to 1 million dollars, or more. It all depends on how much income is to be diverted to the beneficiary. However, there is usually a minimum charge made for the administrative work of the Trust Officer (usually \$25 or \$50 annually depending on locality and the policy of the bank) and therefore trusts of at least \$5,000 would seem advisable.

But whatever amount is used, the donor should proceed with care as any investment that results in lower taxes is usually carefully scrutinized by the Internal Revenue Department. This is especially true of a trust, such as discussed here, which makes the income taxable to the beneficiary and not to the trust.

The simple reversionary trust holds important opportunities for tax savings but all benefits can be thrown away by a wrong sentence, phrase or even a single inadvisable word in the trust instrument. This is truly a time when the phrase "investigate—then invest" is appropriate.

LE ROY B. EVANS

Dow Theory Forecasts, Inc.

DIFFUSE OTITIS EXTERNA

Following a comprehensive discussion of the differential diagnosis and etiologic relationships involved in diffuse otitis externa, the author presents details of an effective method of treatment. He advocates prompt measures to alleviate pain and to control infection, because, he states, "the commonness of pain as the presenting complaint indicates that infection is usually present when the majority of patients seek help."

The author states that in practice, treatment with an agent whose established use is confined to local application is both safe and satisfactory. His best results have been attained with a special liquid preparation—Otobiotic. This nontoxic and nonirritating topical medication which has a physiologic pH of 6.5, contains 3.5 mg. neomycin (as sulfate) and 50 mg. sodium propionate per cc. of alcoholic glycerin vehicle. The spectrum of neomycin includes a gram-negative and gram-positive organisms, notably *Pseudomonas bacilli* and hemolytic staphylococci which are the bacteria found most commonly in ear infections. Propionic acid is particularly effective against the fungi, reported present in about 25 per cent of these cases.

As a routine measure against pain, the author prescribes aspirin and codeine, or, if necessary, a more potent analgesic. He also advocates local cold applications and avoids hot applications.

Of 713 patients treated successfully by the author's method, 347 required only one office treatment; 237 required two visits; 87, three, and 32, four treatments. The remainder required more than four, but their ear conditions had been complicated by perforated drums and other effects of previous chronic otitis media. However, following application of Otobiotic, their ears became free of discharge and improvement in chronic otitis media was noticed.—LAWSON, G. W.: Postgrad. Med., 22:501 (Nov.) 1957.

President's Letter

A REVIEW OF THE YEAR

In January of this year, eleven months ago, I presented in these pages my first letter as President of the Minnesota State Medical Association to the medical profession of Minnesota. In that letter, I called attention to the fact that we are now in the second century of the existence of our great Association, meaning that for more than a century our organization had been working for the greater good and the better health of the people of Minnesota and the nation.

I also wrote that this Association has been in the forefront of medical progress and organization for many years, and I pointed out how selflessly the physicians of the state have served the interests of the organization in everything that has to do with the improvement of the health concerns of the people of Minnesota.

A year ago, I appointed members of committees which were to carry out the many and varied activities of our Association. Now I wish to thank all of you for the notable service you have rendered to the Minnesota State Medical Association and the people of our state. Not a single physician who was asked to serve on a committee or to perform any service for the solution of health problems refused to do so. This is truly a reflection of the willingness with which the physicians of Minnesota serve mankind and strive for the betterment of the health of everyone.

My second letter dealt with Medicare. I outlined the plan of the Federal Government for the medical care of dependents of men in uniform, and I set forth what was required of physicians of the state in making the plan work. I said, "The burden of making this plan succeed rests upon the physicians of Minnesota and the people generally." Thus far, at least, the plan has been successful. We all realize that in such a complicated mechanism many corrective measures have to be taken from time to time, but no major health plan of the magnitude of Medicare could function smoothly without modifications and changes. I wish to acknowledge the remarkable co-operation of the physicians of the state in helping to make this plan successful.

My third letter dealt with the role of Blue Shield in medicine. In this letter, I called attention to the exemplary work that has been accomplished by Blue Shield. I stressed the fact that the current esteem manifested toward Blue Shield by members of the profession here and elsewhere is the result of tireless efforts by a board of directors devoted to a cause. I also set forth some of the problems which face us, and I stressed the fact that members of the profession should be united in their efforts further to improve our economic progeny, meaning Blue Shield.

Requests recently have been voiced in many quarters for greater participation of individual physicians in the Blue Shield corporate structure. It has been suggested that this be accomplished by increasing the number of physicians who constitute the corporate body of Blue Shield. I explained my conviction that members of the medical profession and the directors of Blue Shield Board ought to discuss their problems around a conference table, since the question of increasing the corporate structure of Blue Shield is only one among many. I repeat now my original contention: if members of the medical profession continue to remain loyal to Blue Shield, there can be little question that we shall also continue to maintain an adequate, effective and proper voice in the economy of medical practice.

The annual Scientific Assembly of the Minnesota State Medical Association was held in Saint Paul on May 13, 14 and 15. It was a great success from many standpoints. We were addressed by outstanding national and international authorities in their particular fields of medicine. There was an excellent social program. The banquet was an impressive success, from the standpoints of attendance, menu

and afterdinner activities. Still, I think that the practice of the omission of the President's Address on this occasion (delivery of which was transferred to the General Assembly) deserves some consideration for the future. Those of us who arranged the program of the Scientific Assembly were disappointed in the rather small attendance at the scientific lectures, panels and presentations. I dealt with the problems of the Scientific Assembly and the annual convention in my fourth letter.

In another letter, I addressed myself to some of the problems which confront the Minnesota State Board of Medical Examiners, another group of fine physicians who give themselves selflessly for the improvement of standards for the practice of medicine in this state. I particularly recommend that you read this letter again, because it explains, to some extent, the legal responsibilities of each physician and the high regard in which the Hippocratic Oath should be held by each physician.

In a subsequent letter, I discussed the attempts which have been made by medical societies (the Minnesota State Medical Association, in particular) and industry, to bring about a more satisfactory distribution of physicians. This is a very important field of endeavor, because where it is successful, it inevitably improves the practice of medicine generally. I believe every physician ought to do what he can to help this eminently worthwhile project.

Later, I commended the notion of the Fifty-Year Club, saying that every physician who practices medicine long enough to become a member of that club has performed outstanding service to the people of our state. It should be the ambition of every practicing physician to live long enough to become a member of the Fifty-Year Club.

In another communication, I stressed the importance of physicians' contributing funds to the American Medical Education Foundation, so that those who follow us in the future may be assured of continuing the practice of medicine in a free-enterprise economy, and so that the people will be able to continue to consult the physicians of their choice.

Another letter afforded me the opportunity to review some efforts which I think should be made in keeping the cost of medical care down.

Finally, last month, I remarked on the problem of inclusion of physicians in the Social Security system.

In the present letter, I find myself reviewing the year as a means of taking stock and seeing what, if anything, has been accomplished during that time. I hope that by calling your attention to these matters, and perhaps inducing you to read some of these letters again, I may renew your interest in the activities of the Minnesota State Medical Association and stimulate you to come forth with offers to my successor of suggestions or measures which will improve our stature as physicians in the community in which we live, the standing of our profession as a whole, and to further those actions which are for the greater good of the people whom we serve.

President, Minnesota State Medical Association

Committee Action

Child Health Committee

*Accidents
School Health
Resuscitation of the Newborn
Retarded Children
(and other interests)*

The Child Health Committee of the Minnesota State Medical Association must, of necessity, concern itself with many aspects of the care of children. The main interests of the committee this past year have been in accidents, school health, resuscitation of the newborn, retarded children, cooperation with the Fifth Governor's Council on Children and Youth, cooperation with a Committee on Children's Diagnostic and Treatment Program, in the revision of feeding cards, in the study of neonatal deaths being carried out in Hennepin County, and in various aspects of immunization.

The interest of the committee in work concerning immunization has been shared with that of the Minnesota State Medical Association Committee on Vaccination and Immunization.

Accidents continue to be the leading cause of death among children of the ages of one year to fifteen years. Legislation was passed at the last session of the Minnesota State Legislature which will enable the Minnesota Department of Health to employ a health educator, much of whose work can be devoted to the prevention of accidents. The committee feels that when such a person has been selected, a much more vigorous and effective accident-prevention campaign can be carried out throughout the state. The committee has been working on this problem for a number of years in cooperation with the Minnesota Department of Health.

The creation of a center for the control of poisoning is another aspect of accident-prevention in which we have been interested. Dr. Tague C. Chisholm has been working on the establishment of such a center for several years. During the past year the accident committee of the Minnesota chapter of the American Academy of Pediatrics also has become interested. Dr. Robert Semsch, chairman of the Academy committee in question, with the cooperation of Dr. Chisholm, Dr. A. B. Rosenfield and others, has succeeded in establishing such a center. It is now in operation. Information about the functioning of the center has been and will be distributed by means of the *News Letter*.

Much credit should be given Dr. Tague C. Chisholm, who has worked for many years to

further the cause of prevention of accidents among children in this state.

School health is a very important aspect of the work of the Child Health Committee. One to three members of the committee have attended each of the biennial conferences on school health in Highland Park, Illinois, for the past ten years. These conferences are held on every odd-numbered year, and are sponsored jointly by the American Medical Association and the National Education Association of the United States. Dr. Robert Bergan has been the representative this year.

State school health conferences were begun in 1954, and subsequently were held in 1955 and 1956. The Minnesota State Medical Association has been one of the sponsors each time, the others being the Minnesota State Dental Association, the Minnesota Association of School Superintendents, the Minnesota Department of Health and the Minnesota Department of Education. The meetings have been held at the Center for Continuation Study at the University of Minnesota. Members of the Child Health Committee have attended and participated in these conferences, and also one of our committee members, Dr. Rosenfield, of the Minnesota Department of Health, has planned each of the meetings. It is expected that these meetings will continue to be held, but probably biennially.

Resuscitation of the newborn is a problem confronting not only those in general practice, but obstetricians, pediatricians and anesthesiologists. It is hoped that the combined efforts of the committees representing the foregoing groups can evolve a recommended standard procedure which will be of help to men practicing throughout the state.

The recognition, management and education of retarded children often constitute a difficult problem. In 1950, a nation-wide organization, the National Association of Retarded Children, was organized. Many chapters of this organization are active in Minnesota. The Child Health Committee is trying to maintain contact with them. The committee also is keeping close contact with a federally financed, federal-state study of retarded children in a nonurban area. This study is ex-

COMMITTEE ACTION

pected to be carried on over a four-year period. The four counties selected as sites for the study are Becker, Clay, Otter Tail and Wilkins.

Beginning in 1948, the Governor of Minnesota has appointed a Council on Children and Youth which has held a state-wide meeting in St. Paul or Minneapolis in every even-numbered year. The last meeting was in May, 1956. Members of the Child Health Committee have participated in these meetings, which have provided common meeting places for all organizations in Minnesota interested in children and youth. An advisory council composed of the chairman, vice chairman and consultants of each committee of the Council is continuing now as an active interim body. The chairman of the Child Health Committee is a member of this advisory council.

There is great need in our state for a Children's Diagnostic and Treatment Center for those children who have emotional and psychiatric diseases. In January, 1957, Judge Theodore B. Knudson, of Minneapolis, as a public-spirited citizen, called together representatives of about forty organizations interested in the establishment of a children's psychiatric hospital in Minnesota. The Minnesota State Medical Association was asked to send a representative. President J. Arnold Borgen appointed the chairman of the Child Health Committee to be this representative. A meeting with representatives of the state legislature and government was held at the Coffman Memorial Union at the University of Minnesota on February 16, 1957. Discussion concerned not only the psychiatric hospital but also a center for the outpatient care of children who have psychiatric problems and a screening center for the Youth Conservation Commission. The group recommended that the creation of a staff for the projected hospital be started, that further planning be done, that the legislature at the 1957 session provide for the acquisition of land and also some funds with which to start construction before 1959, if plans could be completed by then. The group was organized as a committee of nine, three of whom are physicians: Dr. Hyman S. Lippman of St. Paul, Dr. Reynold A. Jensen, of the University of Minnesota Medical School, and the chairman of the Child Health Committee. This group met on March 9, and subsequently, in person or by letter testified before a senatorial committee. In spite of the immediate need for these units, it is obvious that more planning is needed. Such planning is continuing. It is hoped that the nucleus for a staff for the new psychiatric hospital can be brought together by use of the presently available but grossly inadequate facilities at the Hastings State Hospital.

The Minnesota Department of Health for many years has published a series of cards bearing recommendations for the feeding of babies. Many physicians throughout the state have found these

cards useful. The cards must be periodically revised, however, and members of the Child Health Committee act in an advisory capacity in that duty.

Members of the Child Health Committee observe with great interest the follow-up study on neonatal deaths which has been carried on in Hennepin County for several years. Ultimately, it is hoped that this study can be enlarged to include the entire state.

Immunization against poliomyelitis and various other similar procedures have been cooperatively discussed with the Committee on Vaccination and Immunization. The chairman of the Child Health Committee, in addition to Dr. Raymond L. Page, of St. Charles, and Mr. Harold Brunn, represented the Minnesota State Medical Association in Chicago in January, 1957, at a national meeting called to deliberate the problem of immunization against poliomyelitis. Members of the Child Health Committee as well as those of the Committee on Vaccination and Immunization act in an advisory capacity to the Minnesota Department of Health for the publishing of the card of recommended practices for immunization procedures.

For many years the Parent-Teachers' Association has sponsored so-called summer roundups throughout the state. The roundups constituted an examination program carried out with the objective of assuring that all children would enter school in good health. The National Parent-Teachers' Association now has recommended, with the cooperative advice of many of the national medical organizations and other organizations interested in children, a program of health supervision which is more nearly adequate than simply examination of a child at the age of five years. Further information about this program will appear in *MINNESOTA MEDICINE*. An editorial on the subject already has appeared in the *Journal of the American Medical Association*. In the old summer round-ups, the Minnesota State Medical Association cooperated on a state level, and through many individual members on a local level. It is to be hoped that this cooperation will continue to be forthcoming in the new program. Dr. Eldon B. Berglund is the member of the Child Health Committee specifically working on this project.

The problems of children in Minnesota are many and varied. The Child Health Committee must be interested in all of them, and enlist the support and help of every member of the Minnesota State Medical Association. Cooperation among committees within the state medical association is most important and necessary. Similarly, cooperation with nonmedical or paramed-

George Earl, M.D., Chairman

SPECIAL CHANNELS FOR PHYSICIANS' EMERGENCY USE URGED

Six radio channels for nationwide emergency use of physicians has been formally recommended to the Federal Communications Commission by the American Medical Association. Use of several channels for non-commercial FM educational broadcast stations was also recommended by the AMA.

Present availability of radio communication channels for the medical profession is very limited and that as a result, the value of this medium in the practice of medicine has not been fully realized, stressed the AMA.

Separate frequencies for hospitals and hospital associations was requested. More effective communication with ambulances and automobiles of staff physicians and surgeons, as well as for use in time of disaster were reasons cited.

U. S. WORKERS' HEALTH COVERAGE DRIVE RESUMED

Fact sheets with questions and answers and charts depicting advantages of the Administration-sponsored plan for prepaid medical care (including catastrophic coverage) and hospitalization will come out every two or three weeks up to return of Congress in January. Distribution by the Civil Service Commission will be to members of House and Senate committees on civil service, government personnel directors and employ unions.

PREPAID MEDICAL PLAN SUBSCRIBERS WANT ADDITIONAL BENEFITS

Michigan prepaid medical plan subscribers want more services and are willing to pay for them.

A public opinion survey conducted by the Michigan State Medical Society included results from an interview survey of 1,000 persons, a questionnaire mailed to more than 60,000 Michigan residents, a separate survey of doctor opinion and a compilation of facts from other surveys on this subject.

Results of the cross-section opinion study involv-

ing the views of more than 12,000 persons were reported.

The survey indicated the majority of the 81% of Michigan residents who are covered by some form of health insurance indicate they are satisfied with the situation. 64.6% have Blue Shield. Only 10% expressed unfavorable opinion of the service, 64% liked it, and 26% were noncommittal. The survey also showed that Blue Shield subscribers believe they pay an average of \$5.95 a month for medical and surgical coverage. The actual average is \$2.83. The majority are willing to pay up to \$6.95 a month in order to obtain additional benefits.

Diagnostic service in hospitals was the most requested added benefit. Many persons also expressed their desire to have Blue Shield include coverage for x-rays, emergency house calls, vaccinations, surgery in doctors' offices, and medical consultations.

Those in favor of such partial coverage voted for \$25 deductible per case rather than \$50 or \$100.

CONSCIOUSNESS OF COST ELIMINATES PATIENT-SURGEON MISUNDERSTANDING

A greater need for the medical profession to directly consider with the patient or his family the financial background of medical care was emphasized by Dr. William L. Estes, in his presidential address before the 43rd annual congress of the American College of Surgeons, in Atlantic City.

He explained that often the potential sources of surgeon-patient misunderstanding might be eliminated if patients were more fully informed regarding the total cost of medical procedure and the extent of benefits from insurance coverage.

A straightforward explanation of the hospital costs and surgical fees, preferably before the operation or at the earliest convenience in the case of an emergency, was the solution suggested by Dr. Estes.

ONE UNDERWRITER INSURANCE COVERAGE ADVISED FOR PHYSICIANS

Maintain your professional insurance under one underwriter is the advice given by Dr. Homer C. Pheasant in an article for the Bulletin of the Los Angeles County Medical Association. He suggests that physicians place their public liability and professional liability with a single insurance company, in order to avoid possible dispute in responsibility of coverage.

Dr. Pheasant cites the classic example of the patient who comes in to an ophthalmologist's office and receives drops in the eyes for the purpose of examination. Upon leaving the doctor's office, the patient stumbles due to a depression in the reception room floor. The premise liability insurance carrier rejects the claim, stating that it is one for the professional liability carrier due to the fact that the patient could not observe the depression as a result of the professional treatment received. In turn, the professional liability carrier alleged that the fall was a result of the depression in the floor and such fall was covered by the public liability carrier.

Dr. Pheasant further suggests the advisability of physicians engaged in group practice maintaining their total professional insurance coverage with a single insurance carrier, to also avoid confusion regarding responsibility.

FULL MEDICAL BENEFITS URGED BY AMERICAN LEGION

The American Legion has expressed increased opposition to the American Medical Association regarding the provision of medical and hospital benefits to veterans for non-service connected illness. The Legion adopted a resolution at its recent convention in Atlantic City reaffirming its support of Veterans Administration health services to non-service connected cases unable to afford private care. A comprehensive study of hospital beds and domiciliary facilities available to veterans suffering chronic diseases was also recommended by the Legion.

In his address to the convention, VA Administrator Harvey V. Higley criticized organized medicine for opposing hospitalization privileges to the non-service connected veteran. He went on to propose construction of an additional 3,300 mental and general medical and surgical beds, chiefly in Florida, Texas and California. At the

same time, he said, steps could be taken to close out 3,900 tuberculosis beds as a balancing measure.

NATIONAL HEALTH SURVEY COMMITTEE APPOINTED

A twenty-four member committee of physicians, educators, nurses, pharmaceutical executives, welfare leaders, public health officials, and insurance executives has been appointed to advise the Public Health Service on operations of the National Health Survey. The continuing project, established by the 1956 Congress was supported by the American Medical Association. However, the AMA cautioned that the operation must be so conducted as to insure general acceptance of its findings.

MEDICAL ASSOCIATIONS GET NEW TAX RULING

Action of Internal Revenue Service in reversing its own 1956 ruling dealing with group medical practice is highly significant. One of its results may be to smooth the road for passage of the Keogh-Jenkins pension plan. The chronology: In January, 1956, IRS ruled that doctors who form an association with the idea of obtaining corporate status benefits—including eligibility of member physicians to subscribe to tax-deferred pension plans—constitute a partnership and so they are disqualified for such plans, which are for *employees* and not employers or partners. This ruling went counter to the Federal court decision earlier (WRMS No. 450), which held that the association operating Western Montana Clinic fulfilled criteria of a corporation, for tax and pension plan purposes.

For nearly two years, tax headquarters in Washington was in the painful position of having to explain over and over again why the doctors in the Montana group could utilize Sec. 401 (a) of Internal Revenue Code—because court said so—while other medical groups administered in identical manner could *not* do so—because IRS said so. Now IRS is “modifying its position,” to use its own words.

New policy: Fact that a medical group sets up a pension plan under 401 (a) will *not* be determinative in categorizing the organization as a partnership or anything else. Rather, the usual tests will be applied to ascertain whether group

has more of the criteria of a corporation than a partnership. Basic criteria, which will hinge on the group's pattern of organization and administration, to be used in making final determination will be published at a later date.

TREATMENT OF MILITARY PERSONNEL OF THE ARMY

Colonel George E. Leone, Army Surgeon, Headquarters Fifth Army Medical Corps, offers the following information to facilitate prompt payment of vouchers for medical care provided Active Army personnel by civilian physicians and hospitals:

Military personnel of the Army who are on authorized absence, should have in their possession Department of Army Form No. 31, "Request and Authority for Absence." The reverse side of this form contains instructions pertaining to medical treatment or hospitalization that may be required while a military person is absent from his home station. Failure to follow these instructions sometimes results in delay in processing bills for care provided by civilian physicians and hospitals. Physicians and hospitals who treat military personnel are urged to assist them in notifying the proper military authorities. The processing and payment of bills for the care of military personnel should not be confused with the medicare program for dependents.

WALTER P. REUTHER GIVES LABOR'S PREPAYMENT GOALS

The following are excerpts from the text of the 1957 Biddle Lecture before the Annual Convention of the Michigan State Medical Society prepared for delivery by Walter P. Reuther, UAW president and read by Leonard Woodcock, UAW vice president.

"The president of the American Medical Association recently deplored labor demands for full payment of all items in medical care. He accused labor, by setting this improperly high standard, of disparaging the performance of existing plans. This charge doesn't even come close to the real issue. We are not, as Dr. Allman seems to think, arguing about extending insurance from covering most of the cost of health to covering all of it. Present insurance plans, at best, cover only one-third of the average family's

health service bill, and we are trying to get benefits extended to cover about another third of health needs.

Workers not only want more and better prepaid health coverage, but they are willing to pay for it. . . . The fact that employers pay premiums in full or in part has led to the false assumption that workers will make unreasonable demands for health coverage because, somehow, they are not paying for it. They are, because employer contributions are monies the worker could otherwise get in cash or other benefits.

Doctors have made great gains out of the fact that the workers have earmarked a portion of their wages as social wages. This has permitted a greater economic allocation to the cost of hospital and medical care, if only by the fact that in this collective way, workers as a whole, have been able to pay for medical care that they could not have paid for on an individual basis. The trouble is that this has led some doctors to assume that the insurance has increased the worker's ability to pay, and they charge more for their services. As a result, we have found that the dollar paid by the employer and the worker under the health plan is not worth as much as the dollar paid out of pocket at the time the service is performed. . . .

Medical societies entered prepayment to avert legislation. They were relatively less concerned with finding the best possible way of prepaying medical care. Rather than to hammer out a whole new set of insurance principles that could be properly applied to medical care, they adapted the ready made doctrines of casualty insurance. . . .

I really don't believe that the average doctor, with his deep interest in medical services, is ready to adopt the insurance industry's concepts of losses rather than benefits, indemnity rather than service, financial devices to inhibit use, to eliminate the small claim and to exclude predictable expenses rather than preventive care, early diagnosis and easy access to health service. . . .

The UAW decided not to launch a separate union medical care program. It has taken the much more difficult course of working with the rest of the community. . . .

We will support experimentation which is soundly conceived and medically oriented and which effectively removes the economic barriers to medical care."

PRELUDE TO PUBLIC RELATIONS

Development of a doctor-hospital-press code for the handling of medical news was the subject of a panel discussion held recently in conjunction with the fall meeting of the Minnesota Associated Press newspapers in Crookston, Minnesota. The Minnesota State Medical Association participated on invitation of the AP, and Dr. C. L. Oppengaard of Crookston, Chairman of our Council, and Mr. John L. Bach of Chicago, Director of Press Relations for the American Medical Association, represented medicine on the panel.

Mr. Paul Swenson, managing editor of the *Minneapolis Star* and chairman of the AP hospital-doctor-press code, was directed to confer with state representatives of the other two groups. After agreement at the state level on the desirability of such a code, local newspapers and hospital and physician groups were urged to work out codes locally.

Similar conferences under county medical society sponsorship have been suggested for other areas of the state.

Recent revision in the American Medical Association code of ethics gives doctors more freedom than they once had in their relations with news media. Use of this latitude in promotion of these three-way conferences will not only produce a better understanding as to handling of medical news but will certainly advance public good will generally.

Hennepin County Medical Society and the Red River Valley Medical Society have already adopted such codes.

The following editorial regarding the medical profession and its relationships to news media appeared recently in the *Detroit Medical News*. Dr. Milton R. Weed is the author.

"Some physicians bitterly critical of medical news reporting refuse to talk to reporters. They accuse newspapermen of sensationalism, inaccuracy, lack of perspective, and even purposeful distortion of news. Almost all doctors dread having their names appear in newsprint for, if an article is favorable, they may be accused of self-laudation, and if it is not, they are likely to be condemned for undermining the public's confidence in the profession.

"Every science writer knows, however, that to write with authority he must cite his references as accurately as a scientist documents his premises. And his problem is complicated by news competition and deadlines. This situation creates misunderstanding and recrimination.

"Actually newspapermen and doctors have much in common.

"Both are usually motivated by public interest. The majority of editors are men of discernment, high ideals and public spirit and this attitude is transmitted in greater or lesser degree to their staffs. The doctor, bound by oath and the ethical code to protect his

patient, the best interests of the public and the honor of his profession, may forget that reporters are responsible people too: they do not deliberately embarrass their sources of information—they may want to use them again—, or make fools of their paper or its readers, but they are determined to provide the public with legitimate news and any attempt at suppression arouses suspicion of skullduggery.

"Physicians and newspapermen also agree that the public is entitled to medical news fairly and accurately presented. Medicine, in self interest, needs good science reporting to interpret its discoveries, health information and viewpoints to the public which supports it.

"Obviously, better medical news reporting cannot be realized if scientists refuse to talk to newspapermen. Nor can it be achieved by cutting off any authoritative source of information, or by declining to give the facts, background, or perspective—ethical and scientific—needed for good reporting. . . .

"Can more be done? Should not all physicians feel free to talk to reporters? Most reporters we have encountered are sympathetic to patients' rights and the public's interest when they understand how these are involved. From doctors seeking self laudatory publicity we have little to fear. Reporters conditioned by press releases and innumerable interviews with ax-grinding publicity-seekers can spot a phony faster than a pediatrician can recognize chicken pox.

"It seems to us that all physicians ought by every means available to cultivate intelligent understanding and honest co-operation with newspapermen in the interest of accurate medical news. Maybe we are naive; maybe it just happens that the reporters we know are exceptional guys—none writes for *Confidential*."

COMMITTEE ACTION

(Continued from Page 879)

ical groups interested in problems of children also is essential and can be very rewarding.

Finally, I would pay tribute to the members of the Child Health Committee who have served with me these past 11 years: Drs. R. O. Bergan, Eldon B. Berglund, Tague C. Chisholm, George Erickson, John J. Galligan, O. H. Jones, A. B. Rosenfield, Viktor O. Wilson, Charles W. Rogers, Edward Zupanc, William B. Richards, Stuart L. Arey, Frank G. Hedenstrom, Roland E. Nutting, Lawrence F. Richdorf, Raymond J. Josewski, Roger L. J. Kennedy, Irvine McQuarrie, Oswald S. Wyatt, Edward E. Novak, C. H. Schroder, Erling S. Platou, and Lyman R. Critchfield. No chairman could wish for a more willing and able group of men.

GEORGE B. LOGAN, M.D.,
Chairman

Meetings and Announcements

STATE

MINNESOTA STATE MEDICAL ASSOCIATION, 105th annual meeting, Minneapolis, May 22, 23 and 24, 1958. Business sessions and exhibits, Minneapolis Auditorium. Headquarters, Leamington Hotel.

NATIONAL

American College of Surgeons, sectional meeting, Des Moines, Iowa, March 27-29, 1958.

American College of Chest Physicians. Warwick Hotel, Philadelphia, Pennsylvania, December 2-3, 1957.

American Gastroenterological Association, 59th annual meeting, Washington, D. C., May 30-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

Cardiac Symposium sponsored by the American Heart Association. Valley Ho Hotel Scottsdale, Arizona, January 31-February 1, 1958.

Mediclinics of Minnesota. Fort Lauderdale, Florida, March 2-12, 1958.

Second Illinois Congress on Maternal and Infant Care. Hotel Pere Marquette, Peoria, Illinois, February 4-6, 1958.

INTERNATIONAL

Fifth International Congress on Diseases of the Chest, sponsored by American College of Chest Physicians, Tokyo, Japan, September 7-11, 1958.

Fifth International Congress of Internal Medicine, Philadelphia, Pennsylvania, April 24-26, 1958. Edward R. Loveland, Secretary-General, 4200 Pine Street, Philadelphia 4, Pennsylvania.

International Society of Internal Medicine, Fifth International Congress of Internal Medicine, Philadelphia, Pennsylvania, April 24-26, 1958. Edward R. Loveland, Secretary-General, 4200 Pine Street, Philadelphia 4, Pennsylvania.

World Congress of Gastroenterology, Washington, D. C., May 25-31, 1958. H. M. Pollard, M.D., Secretary-General, University Hospital, Ann Arbor, Michigan.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, are as follows:

December 5-7	Fractures for General Physicians
January 6-11	Ophthalmology for Specialists
January 9-11	The Newer Drugs in General Practice
Jan. 30-Feb. 1	Emergency Surgery for General Physicians
February 6-8	Cardiovascular Diseases for General Physicians
February 10-15	Neurology for General Physicians and Specialists

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

NURSING LICENSE RENEWAL FOR 1958

Currently licensed Minnesota registered nurses and licensed practical nurses who intend to practice in Minnesota next year are reminded to renew their licenses prior to January 1, 1958. The 1958 renewal fee of \$1.00 (money order preferred) is to be sent to the Minnesota Board of Nursing, 700 Minnesota Building, St. Paul 1, Minnesota. A late penalty fee of \$1.00 will be charged for renewals postmarked after December 31, 1957.

Requests for placement in the non-practicing status may be made instead of renewal of license by those currently-licensed nurses who do not intend to practice in Minnesota at any time in 1958.

CHICAGO OPHTHALMOLOGICAL SOCIETY

The Chicago Ophthalmological Society will hold its annual clinical conference on February 21 and 22, 1958, at the Drake Hotel in Chicago, Illinois.

The guest speakers will include Dr. Wendell L. Hughes, Hempstead, N. Y.; Dr. P. Robb McDonald, Philadelphia, Pa.; Dr. Phillips Thygeson, San Jose, California; Dr. Lorenz E. Zimmerman, Washington, D. C.; Dr. Eugene R. Folk, Chicago, Illinois; Dr. Orville E. Gordon, Chicago, Illinois; Dr. William F. Hughes, Chicago, Illinois; Dr. Peter C. Kronfeld, Chicago, Illinois; Dr. David Shoch, Chicago, Illinois; Dr. Derrick Vail, Chicago, Illinois, and Dr. Howard L. Wilder, Chicago, Illinois.

The subjects will include a symposium on the complications of ophthalmic surgery, the zonule of the lens, glaucoma and retinal detachment surgery, plastic surgery techniques, management of glaucoma and cataract, melanotic tumors of the iris, and the structure of the vitreous.

Registration fee for the entire course including round table luncheons and buffet supper is \$45.00 and may be payable to the Registrar: Mrs. Edward J. Ryan, 1150 North Lorel Avenue, Chicago 51, Illinois.

The Fourteenth Annual Samford R. Gifford Memorial Lecture will be delivered by Dr. Phillips Thygeson of San Jose, California, on Friday, February 21, 1958, at the Drake Hotel at 5:15 p.m. All ophthalmologists are invited to attend the Gifford Memorial Lecture and the buffet supper which follows.

RED RIVER VALLEY MEDICAL SOCIETY AND AUXILIARY MEET

The Red River Valley Medical Society and Auxiliary held their annual fall dinner meeting at the Rex Cafe, Thief River Falls, in October.

Dr. W. E. Anderson of Clearbrook, president of the Society, conducted the program, which included a paper on surgical treatment of coronary heart disease given by Dr. Nathan K. Jensen of Minneapolis.

Members of the Auxiliary met at the home of Mrs. Wm. Feigal.

Medical Economics

Activity in Washington slows; new fiscal year begins, 588
 Administration endorses barbiturates control bill, 444
 AFL-CIO to fight medical society actions, 660
 Aircaide team to take legislative issues to cities, 135
 AMA announces administrative changes; organization of new committee, 662
 AMA House of Delegates acts upon wide variety of subjects, 514
 AMA legislative machinery summarized, 54
 AMA protests President's budget, 516
 Bills introduced on tax deferment for self-employed, 190
 Blue Cross issues annual report, 516
 British M.D.'s continue to consider walk-out, 340
 British physicians quoted, 192
 Capitol action slow on health bills, 190
 Chiropodists bidding for greater recognition, 662
 Civil service working on new federal health plan, 54
 Consciousness of cost eliminates patient-surgeon misunderstanding, 880
 Contributions to medical schools increase, A-36
 Costa Rican doctors attempt to finance retirement fund, 275
 Disabled "over fifty" start drawing monthly benefits, 517
 Earnings of physicians surveyed, 276
 85th Congress gets under way with record number of bills introduced, 134
 Facts on medical education (AMEF state chairmen to meet, more women studying medicine, states producing most medical students), 56
 FDA circularizes on Hoxsey cure, 192
 February selective service call largest in two years, 55
 Federal appropriations for U. S. public health service, 442
 Federal health legislation outlined, 274
 Fees increased and authorization time extended in home-town care program, 734
 Figures on life expectancy, 590
 First checks for the disabled go to 100,000, 660
 FTC to question eighteen firms on antibiotics profits, 662
 Full medical benefits urged by American Legion, 881
 Government to spend \$14 billion for welfare in next budget year, 275
 Group Health Federation meets in Two Harbors, 661
 Health groups asked to aid Hungarian medical personnel, 135
 Health statistics revealed, 193
 Highlights of HEW budget reviewed, 338

Hospital and surgical care through insurance company policies, 814
 Hospital medical care payments total over \$2 billion, 274
 How to write Minnesota congressmen, 191
 Joint declaration on physician-hospital relations, 445
 Legal medical matters (close cooperation between AMA and ABA, AMA-ABA action on Jenkins-Keogh bill, the physician as a medical witness), 55
 Legislative review (1957), 735
 Little health legislation activity on Capitol Hill, 515
 Major protection policies are popular, 735
 Medical associations get new tax ruling, 881
 Medical quackery in mails reaches new high, 517
 Medical societies to base fees on price index, 815
 Medical student statistics compiled, 276
 "Medicare" is big business in Minnesota, 734
 Medicare plan launched in December, 54
 Medicare program running smoothly, 191
 Minnesota included in award for research building, 339
 Minnesota physicians contribute \$28,000 to AMEF, 276
 More talk of social security for physicians, 339
 National health survey begun, 444
 National health survey committee appointed, 881
 National medical library selects architects, 662
 New bills filed in Congress; more hearings scheduled, 338
 New doctor-draft plan due for House hearing, 339
 New health legislation in Congress, 443
 One underwriter insurance coverage advised for physicians, 881
 Osteopath, naturopath bills passed in Utah, 517
 Personnel changes in new department (Health, Education and Welfare), 135
 Physicians reminded of professional tax deductions, 136
 Physicians threaten strike in Britain, 275
 Physicians voice objections to Medicare "red tape," 816
 Possible battle looms over control of corporation, 590
 Prelude to public relations, 883
 Prepaid medical plan subscribers want additional benefits, 880
 President's budget request for NEW tops \$3 billion, 192
 Record number of health-medical bills enacted by 85th Congress, 814
 Reuther, Walter P., gives labor's prepayment goals, 882
 Rise in hospital admissions indicated, 55
 Rules on osteopath commissioning outlined, 191
 Russian technology is rapidly approaching U. S. standards, 275
 Series of important resolutions passed at annual MSMA meeting, 514
 "Sick pay" makes lost time almost profitable, 662
 Special channels for physicians' emergency use urged, 880
 Statistics on physicians and nurses released, 55
 Statistics on obstetrical costs, hospital occupancy, 340
 Statistics revealed on cost of prescriptions, 661
 Supreme court declines to support naturopathy, 330
 Survey conducted on doctors' dues, 516
 Survey reports of interest to physicians (the doctor's investment woes, income comparison survey results), 56
 Survey reports on physicians, 136
 Tax relief for Canadian self-employed, 735
 Treatment of military personnel of the army, 882
 Twenty-four physicians receive Sears-Roebuck grants, 136
 Two government agency reports concern cost of medical care, 590
 U. S. aid to medical training increases, 443
 U. S. contribution to WHO budget drops, 516
 U. S. delegates named to WHO meeting at Geneva, 444
 U. S. GP's support British colleagues, 516
 U. S. Steel offers new major medical coverage, 56
 U. S. workers' health coverage drive resumed, 880
 VA Hospital needs cited, 816
 Veterans affairs committee reviews medical care, 274

War service brings some M.D.'s into social security, 191
Washington selected as medical library site, 444

Medical-Legal Opinions

New tax regulations, 60
Obtaining consent of patient for surgery, 131
Sterilization, 60
Test for alcohol, 206

Meetings and Announcements

Academy of Psychosomatic Medicine, 665
American College of Chest Physicians, prize essay contest (Oct.) A-50
American College of Physicians to hold postgraduate courses, 342
American College of Surgeons to hold sectional meeting in Saint Paul, 140
American Foundation for Allergic Diseases, Fellowships available from, (Nov.) A-46
American Medical Association, 665
Chicago Ophthalmological Society, 884
Congress of Legal Medicine and Law-Science Problems, 454
Congress of Physical Medicine and Rehabilitation to meet at Rochester, 209
Continuation courses, 342, 592, 666. (Oct.) A-50, (Nov.) A-46, 884
Essay contest, 598
Fellowships available from National Foundation for Infantile Paralysis, 597
Fellowships for vacation time study for medical students, 69
Films available for medical groups, 599
Fourteen fellowships in psychiatry announced, 288
Harvey Tercentenary Congress, 69
International prizes for family physicians, 70
Kenny Foundation scholarships, (Oct.) A-50
Laboratory assistants graduate in September, 599
Lecture on hemophilia, 342
Mayo Clinic to present clinical reviews, 69
Medical continuation courses at University of Minnesota, 70, 210
Minnesota Academy of General Practice, 596
Minnesota Heart Association, 666
Minnesota Medical Foundation Day, 666
Minnesota State Medical Association
Highlights of 104th annual meeting, 518
Preliminary program—104th annual meeting, 204, 283
Revision of articles of incorporation, constitution and by-laws, 194
Roster, 347
National hearing week, May 5-11, (April) A-38
New law on emergency admissions to state mental hospitals, 598
New York University Post-Graduate Medical School announces courses, 288, (Oct.) A-52
Northern Minnesota Medical Association, 595
Nursing license renewal for 1958, 884
Olivia girl wins 1956 AAPS essay contest, 529
Omaha Mid-West Clinical Society, (Oct.) A-51
Pathologists meet, 598
Red River Valley Medical Society and auxiliary meet, 884
Rural medical scholarship awarded to Anoka man, 210
Southern Minnesota Medical Association, 596
State Medical Association offers science fair scholarships, 210
State Medical Association officers announced, 69
State ophthalmologists urged to aid firearms safety training program, 210
Symposium on alcohol, 288
Symposium on peripheral vascular disease, 596
Symposium on radioisotopes, 665
Symposium on recent development in diabetes mellitus, 666

Tenth annual postgraduate course on diseases of the chest, 209
Two fellowships to recruit workers in audiology and speech, 666
University course on advanced oral pathology, 598, (Oct.) A-51
Urology award, 529
Van Meter prize award, (Oct.) A-50
World Congress of Gastroenterology, 209
World Health Assembly to meet in Minneapolis, (Nov.) A-46

Minnesota State Board of Medical Examiners

Chaska, Minnesota, man sentenced in Minneapolis for basic science violation, (March) A-34
License of Saint Paul physician revoked, (March) A-34
Minneapolis man sentenced to four-year prison term for abortion, (Aug.) A-34
Minneapolis woman sentenced to four-year term for abortion attempt, (April) A-47
Orderly in Minneapolis nursing home sentenced for violation of drug ordinance, 345
Physician's license revoked, 520, (Aug.) A-32
Physician's license suspended for three years, 520
Physicians licensed February 10, 1956, 447
Physicians licensed May 11, 1956, 448
Physicians licensed July 6, 1956, 449
Physicians licensed November 9, 1956, 451
Prior Lake woman sentenced for obtaining narcotics by means of forged prescription, 73
Saint Paul dentist sentenced to eight-year prison term on abortion charge, (March) A-34
Saint Paul barber sentenced for illegal sale of medicine, 453
Saint Paul man sentenced for abortion attempt, 453
South Saint Paul man sentenced for attempted abortion, (Aug.) A-32
Two Minneapolis men ordered to serve terms for abortion, 346
Two Minneapolis men sentenced for abortion, 74
Two sentenced at Le Center for abortion, 73
Two University of Minnesota graduate students charged with abortion, (Aug.) A-32

Miscellaneous

Minnesota Blue Cross-Blue Shield, (March) A-49, (April) A-46, (May) A-37, (June) A-55, (Aug.) A-40, (Sept.) A-62, (Oct.) A-62, (Nov.) A-68
New film on professional liability hazards, (Aug.) A-42

In Memoriam

JOHN LEO DELMORE, SR.

Dr. John Leo Delmore, Sr., Roseau physician and surgeon, died November 7, 1957, at his home. He was seventy years old. He had served as physician and surgeon in the Roseau area since 1909.

In 1949, Dr. Delmore was publicly honored for forty years of service to his community. He was also honored in 1954 by the Minnesota State Medical Association with the presentation of a gold-inscribed associate membership plate in recognition of his forty years of service in the medical profession.

Dr. Delmore was born in 1886 in Elroy, Wisconsin, and received his preliminary education in the Marshfield, Wisconsin, schools. He was a graduate of the University of Minnesota School of Medicine, class of 1909. He interned at St. Joseph's Hospital in St. Paul.

Positions and professional affiliations held by Dr. Delmore included: Superintendent and Chief of Staff at Budd Hospital, Roseau, Phi Beta Pi Medical Fraternity, Red River Valley Medical Society, Minnesota State Medical Association, and American Medical Association.

He is survived by his wife; four sons—Dr. John, Roseau, Dr. Robert, New Orleans, La., Michael, Manitowoc, Wis., and James P., Rochester; three daughters—Mrs. Louise LaBonte, Roseau, Mrs. D. L. Bray, Algona, Iowa, and Sister St. Jean, Grand Forks, North Dakota.

JAMES N. DUNN

Dr. James N. Dunn, St. Paul physician, died at his home November 15, 1957, at the age of sixty-six.

He was former chief of staff at St. Joseph's Hospital, St. Paul. At the time of his death, he was on the staff of Ancker and St. Joseph's hospitals and on the courtesy staff of St. Luke's Children's and Miller hospitals.

Dr. Dunn was a past president of the Ramsey County Medical Society. He was an active member of the Minnesota State Medical Association, the American Medical Association, and the American College of Physicians. He was a former member of the Ramsey County Welfare Board and, during World War II, he served on the advisory board for draftee examinations and on the state board for procurement of medical officers.

Dr. Dunn was born in Alexandria, South Dakota, and received his preliminary education at North High School in Minneapolis. He was a graduate of the University of Minnesota School of Medicine, class of 1916. Special work included one year of internship at St. Paul Ancker Hospital and one year at Base Hospital 64, Fort Riley, Kansas. In 1932, he did postgraduate work at St. Bartholomew's Hospital in London, England.

Survivors include his wife, Pearle; a son, James M., Ames, Iowa; four daughters, Mrs. Donal Barrer, Bethesda, Maryland; Mrs. Keith Kuehn, Kenosha, Wisconsin; Mrs. Vincent Erickson, North Hollywood, California; and Mrs. Glabe Staffin, St. Paul; two sisters, Mrs. George Frey, Luverne, and Mrs. Marshall Osborne, Inglewood, California; and eleven grandchildren.

EDWARD QUIRIN ETEL

Dr. Edward Quirin Ertel, Ellendale, Minnesota physician for more than forty-eight years, died in an Albert Lea hospital, October 29, 1957, at the age of 76.

He began his practice in the Ellendale community, September 23, 1908, and for many years was that community's only physician.

Dr. Ertel was a graduate of the Medical College of Iowa, class of 1907.

He served as a member of the Ellendale school board for thirty-six years. In 1956, Dr. and Mrs. Ertel donated a five-acre tract of ground to the school system of that community to be used as an athletic field. In addition, Dr. Ertel had also served on the Ellendale village council, had been an Ellendale health officer, and was a member of the Steele County health board.

He was a member of the Minnesota State Medical Association and former president of the Steele County Medical Society.

Dr. Ertel is survived by his widow. The couple had no children.

CHARLES E. PROSHEK

Dr. Charles E. Proshek, formerly honorary Czechoslovakian consul in Minneapolis, died October 30, 1957, at his summer home. He was sixty-four.

Dr. Proshek, native of New Prague, Minnesota, received his degree from the University of Minnesota Medical School in 1917.

For more than thirty-five years, Dr. Proshek practiced medicine in Minneapolis. He was a staff member of Swedish Hospital and a member of Hennepin County Medical Society, Minnesota State Medical Association, and the American Medical Association.

After World War I, Dr. Proshek worked in Europe with the Red Cross in settling displaced persons. Following World War II, he served in a similar capacity with the United Nations Relief and Rehabilitation Association. The assignment included a one-year term with the United States Public Health Service in Munich, Germany. Dr. Proshek resigned from his consular post in 1948 after twenty years of service.

Survivors include his wife, Gabriela; a son, Dr. Lumir C. Proshek, Edina; three brothers, Frank and George, New Prague, and Theodore, Colorado Springs, Colorado; three sisters, Mrs. Jenny Vanasek, New Prague, Mrs. Antoinette Machacek, Northfield, and Mrs. Barbara Benjamin, Washington, and a grandson.

Many physicians do not make routine pelvic examinations, although this procedure should be an integral part of the periodic health examination of every woman.

* * *

The principal symptoms of cerebellar tumor are unsteadiness of gait with headache and vomiting.

* * *

The most important part of a complete health inspection—and a part not at present carried out by the general practitioner—is the rectal examination; this should include a digital examination and sigmoidoscopy.

More direct control of specific rheumatic types

● Effective, fast anti-rheumatic activity *without experimentation*—that's the simple truth about P-B-SAL-C (Ulmer) combinations which have been demonstrated in a wide range of rheumatic diseases.

Relief is not only fast, but is sustained on small daily dosage. Specially fabricated combinations of P-B-SAL-C provide a choice in specific rheumatic disorders. In severe joint pain (particularly in persons over 40, say leading medical authorities), P-B-SAL-C with COLCHICINE can be used diagnostically to ascertain or disprove a gouty condition. Colchicine is specific for the diagnosis and control of gout.

And for muscular spasm associated with severe joint pain, P-B-SAL-C WITH ESOPRINE provides a two-way action to help control both pain and spasm.

Where arthritis is complicated by cardiovascular conditions, P-B-SAL-C SODIUM FREE brings relief without disturbing electrolyte balance. Neither sodium nor potassium are contained in this combination.

In routine therapy, high plasma salicylate levels are quickly reached with the basic combination, P-B-SAL-C.

Whichever P-B-SAL-C combination is prescribed, you're assured that thousands of patients have experienced rapid relief and sustained it at a very moderate cost. Let us forward your name to our nearest detail man for complete information.

Woman's Auxiliary

GOODHUE COUNTY AUXILIARY HOLDS MEETING

The Goodhue County Medical Auxiliary held its October meeting at the St. James Hotel, Red Wing. Following luncheon, a business meeting was held, presided over by Mrs. Ezra Bridge of Mineral Springs Sanatorium, Cannon Falls. It was with deep regret that the resignation of Mrs. Bridge was accepted. Dr. and Mrs. Bridge are leaving shortly to make their home in Port Huron, Michigan, where Dr. Bridge will enter private practice.

"Health is a Joint Endeavor" is the theme for the ensuing year, not only on a county level, but throughout the nation.

Following the meeting, the group proceeded to the Washington School, where they observed the work being done with exceptional children. This project is one of several in which the auxiliary is vitally interested and lends its support.

RAMSEY COUNTY AUXILIARY NEWS

Board members of the Women's Auxiliary to the Ramsey County Medical Society met in the medical library on November 11. Mrs. Herman Wolff, president, presided and members made cancer dressings during and following the meeting.

Mrs. Ralph L. Olsen attended a Traffic Conference, and Mmes. Leroy Fox, Walter Gardner, and Herman Wolff attended a Tuberculosis Christmas Seal dinner on October 28, as Auxiliary representatives. Reports on the meetings were given.

The Auxiliary has agreed to collect medical magazines for the Bruce Publishing Company, who will send them to foreign countries. The magazines will be made available to interested people in other countries.

Members of women's clubs in St. Paul are competing in a table decorating contest at the Golden Rule. Mrs. Albert Hayes will represent the Ramsey County Auxiliary.

The monthly luncheon meeting was held on November 18 in the University Club. Mrs. John Meade and Mrs. Burtis Mears, program chairmen, presented Mr. Warren T. Mosman, art consultant for Ellerbe and Company, who spoke on the very interesting topic, "Art in Professional Buildings."

RANGE AUXILIARY DISCUSSES YEAR'S PROGRAM

The Range Medical Society Auxiliary held its October meeting in the Androy Hotel, Hibbing. Dinner was

enjoyed with members of the Range Medical Society. A short business meeting followed.

Mrs. Richard Barnes of Aurora, auxiliary president, reported on the instructional program she had attended two weeks previously in Minneapolis.

The auxiliary program for the coming year will stress safety, mental health, the American Medical Education Foundation, and *Today's Health* magazine.

The next auxiliary meeting will be held in Virginia at Hotel Coates.

MRS. C. L. OPPEGAARD ADDRESSES ZUMBRO VALLEY AUXILIARY

Mrs. C. L. Oppegaard, Crookston, state auxiliary president, was guest speaker at the November 13 luncheon meeting of the Zumbro Valley Medical Auxiliary, held at the Rochester Country Club. Other state officers present were Mrs. William Gjerde, Lake City, state mental health chairman, and Mrs. W. O. Finkelnburg, Winona, state cancer chairman. Also present were members from Austin, Winona, Lake City, Cannon Falls and Spring Valley.

Mrs. Howard Polley, Region One advisor, presided at the meeting and introduced Mrs. Oppegaard. The latter outlined the four main objectives of the auxiliary for the coming year. They are: (1) promotion of the American Medical Education Foundation or fund, (2) promotion of subscriptions to "Today's Health," a magazine for lay people, (3) the safety project, which includes sponsoring of drivers' education for high school students, (4) increased interest in legislation as it affects medical practice.

Mrs. W. E. Wellman, president of the Zumbro Valley Auxiliary and former state AMEF chairman, emphasized the importance of doctors and their wives continuing their support of the AMEF as a means of giving financial aid to medical students.

Mrs. Gjerde requested more volunteer help in all the state mental health hospitals.

MINNESOTA BLUE SHIELD-BLUE CROSS

Minnesota Blue Shield has provided benefits for the delivery of over 111,615 new Minnesotans. This is the number of obstetrical claims paid by Blue Shield from the date the plan began operations through August, 1957.

Obstetrical benefits provided by Blue Shield as of August 31, 1957, total over \$6,494,000. This figure is equal to an average Blue Shield obstetrical allowance of approximately \$58, because from the plan's beginning through the year 1953, the maximum obstetrical benefit under Plan A contracts was \$50. However, the maximum Plan A obstetrical benefit was increased to \$60 on January 1, 1954, and at the same time the waiting period for obstetrical benefits was reduced from ten to nine months. Moreover, on March 1, 1954, the Plan B contract, which has obstetrical benefits of \$100 was offered to the public.

During the first eight months of 1957, Blue Shield provided benefits for 14,121 obstetrical deliveries, a monthly average of more than 1,765. The amount paid by Blue Shield for obstetrical services during this eight-month period was \$927,969, an average obstetrical benefit of over \$65. The amount in excess of \$60 is attributable primarily to obstetrical benefits provided under Plan B contracts.

Blue Cross payments totaling \$20,916,957.18 have been provided for 151,325 Minnesotans during the first nine months of 1957. These totals reflect 908,294.2 days of hospital care.

The incidence rate of hospitalization represented by this experience was 482 cases paid per year per 1,000 contracts protected, an increase of 5.5 per cent compared with the hospitalization experience during the same period of 1956.

The leading cause for hospitalization of Minnesota Blue Cross subscribers during the first nine months of 1957 was accidental injury. Accidental injury was also the leading reason for increased incidence over the same nine-month period in 1956.

Of the 151,325 cases paid for all subscribers during the first nine months of 1957, 25,679 required care for accidental injuries.

Although leading in number of cases paid, accidents ranked seventh in dollar cost. Approximately \$1,400,000 in hospital benefits have been provided for accidental injury of Blue Cross subscribers.

During this same nine-month period (January through September) 24,112 Blue Cross subscribers were admitted to hospitals for conditions of pregnancy. Benefits provided for this category exceeded \$3,000,000. Conditions of pregnancy cases amounted to 15.9 per cent of Blue Cross cases paid, or the second largest reason for increased Blue Cross incidence.

The third ranking reason for hospitalization of Blue Cross subscribers was respiratory illness. 20,174 cases, or 13.3 per cent of Blue Cross cases paid for the first nine months of 1957, were for this reason. Benefits paid for respiratory conditions amounted to approximately \$1,950,000.

Ranking fourth in the reasons for hospitalization of Blue Cross subscribers was digestive illnesses. Blue Cross benefits during the first nine months of 1957 in this category approximated \$3,600,000. Although ranking fourth in frequency of occurrence, digestive diseases outrank all other categories in benefits paid.

A contributing reason for this high-benefits-paid figure is the fact that digestive diseases require a longer period of care than any other three leading causes of hospitalization. Digestive illness required an average of 7.2 days per case, compared to 3.1 days for accidents, 4.7 days per case for conditions of pregnancy, and 4.4 days per case for respiratory illness.

As of September 30, 1957, there were 427,359 Blue Cross contracts in effect representing 1,127,678 Minnesotans.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

TRAITÉ DE TECHNIQUE CHIRURGICALE. By B. Fey, P. Mocquet, S. Oberlin, and others. Second ed. Vol. 5—Organes génitaux de la femme, Césariennes, Mamelle. 780 pages. Illus. Price 300 fr. Paris: Masson et Cie, 1956.

This volume of surgical technique, which is one of a series, is concerned with the female genital organs. The book is well written and fairly complete. The illustrations are good. As with many volumes like this, some of the procedures are obsolete and others are not too critically reviewed. All in all, though, it is a fairly good review. The index is adequate.

C. E. R.

TUBERCULOSIS: EVERY PHYSICIAN'S PROBLEM.

By J. Arthur Myers, Professor of Internal Medicine and Public Health, Medical and Graduate Schools, University of Minnesota. 290 pages. Illus. Price \$7.50. Springfield, Ill.: Charles C Thomas, ©1957.

Chemotherapy may have postponed deaths from tuberculosis, thus decreasing the mortality rates, but it has not

eradicated the problem of the disease; and, in fact, chemotherapy may lull us into a feeling of false security.

Dr. Myers has summed up for the physician and the public health worker the problem of tuberculosis—from his brief historical sketch in the first chapter to a summary of the role of the physician, in the final chapter. Feeling "that ultimately eradication of tubercle bacillus is dependent upon adequate diagnosis, proper treatment and preventive measures directed by physicians and their allies," he has set forth in readable style a concise description of the tubercle bacillus and how it invades the human body, of the diagnostic procedures and treatment employed today in each clinical type of the disease, and of the methods known and used for prevention and control.

An interesting chapter is on "Anachronisms," which, in this book, are "theories and opinions which have long been in use but have proved of no value or are even harmful."

It is due in large part to Dr. J. Arthur Myers that Minnesota is one of the leaders in the fight against tuberculosis, and in this book he draws, of course, from his experiences and cites methods used in this state.

This will serve well as a handbook on the problems of tuberculosis; and for those who wish to pursue some phase further, the author has included references at the end of each chapter.
